1 □ FUNCTIONS AND MODELS

1.1 Four Ways to Represent a Function

In exercises requiring estimations or approximations, your answers may vary slightly from the answers given here.

1. (a) The point $(-1, -2)$ is on the graph of f , so $f(-1) = -2$.
(b) When $x = 2$, y is about 2.8, so $f(2) \approx 2.8$.
(c) $f(x) = 2$ is equivalent to $y = 2$. When $y = 2$, we have $x = -3$ and $x = 1$.
(d) Reasonable estimates for x when $y = 0$ are $x = -2.5$ and $x = 0.3$.
(e) The domain of f consists of all x -values on the graph of f . For this function, the domain is $-3 \leq x \leq 3$, or $[-3, 3]$. The range of f consists of all y -values on the graph of f . For this function, the range is $-2 \leq y \leq 3$, or $[-2, 3]$.
(f) As x increases from -1 to 3 , y increases from -2 to 3 . Thus, f is increasing on the interval $[-1, 3]$.
2. (a) The point $(-4, -2)$ is on the graph of f , so $f(-4) = -2$. The point $(3, 4)$ is on the graph of g , so $g(3) = 4$.
(b) We are looking for the values of x for which the y -values are equal. The y -values for f and g are equal at the points $(-2, 1)$ and $(2, 2)$, so the desired values of x are -2 and 2 .
(c) $f(x) = -1$ is equivalent to $y = -1$. When $y = -1$, we have $x = -3$ and $x = 4$.
(d) As x increases from 0 to 4 , y decreases from 3 to -1 . Thus, f is decreasing on the interval $[0, 4]$.
(e) The domain of f consists of all x -values on the graph of f . For this function, the domain is $-4 \leq x \leq 4$, or $[-4, 4]$. The range of f consists of all y -values on the graph of f . For this function, the range is $-2 \leq y \leq 3$, or $[-2, 3]$.
(f) The domain of g is $[-4, 3]$ and the range is $[0.5, 4]$.
3. From Figure 1 in the text, the lowest point occurs at about $(t, a) = (12, -85)$. The highest point occurs at about $(17, 115)$. Thus, the range of the vertical ground acceleration is $-85 \leq a \leq 115$. In Figure 11, the range of the north-south acceleration is approximately $-325 \leq a \leq 485$. In Figure 12, the range of the east-west acceleration is approximately $-210 \leq a \leq 200$.
4. *Example 1:* A car is driven at 60 mi/h for 2 hours. The distance d traveled by the car is a function of the time t . The domain of the function is $\{t \mid 0 \leq t \leq 2\}$, where t is measured in hours. The range of the function is $\{d \mid 0 \leq d \leq 120\}$, where d is measured in miles.

2 □ CHAPTER 1 FUNCTIONS AND MODELS

Example 2: At a certain university, the number of students N on campus at any time on a particular day is a function of the time t after midnight. The domain of the function is $\{t \mid 0 \leq t \leq 24\}$, where t is measured in hours. The range of the function is $\{N \mid 0 \leq N \leq k\}$, where N is an integer and k is the largest number of students on campus at once.

Example 3: A certain employee is paid \$8.00 per hour and works a maximum of 30 hours per week. The number of hours worked is rounded down to the nearest quarter of an hour. This employee's gross weekly pay P is a function of the number of hours worked h . The domain of the function is $[0, 30]$ and the range of the function is $\{0, 2.00, 4.00, \dots, 238.00, 240.00\}$.

5. No, the curve is not the graph of a function because a vertical line intersects the curve more than once. Hence, the curve fails the Vertical Line Test.
6. Yes, the curve is the graph of a function because it passes the Vertical Line Test. The domain is $[-2, 2]$ and the range is $[-1, 2]$.
7. Yes, the curve is the graph of a function because it passes the Vertical Line Test. The domain is $[-3, 2]$ and the range is $[-3, -2) \cup [-1, 3]$.
8. No, the curve is not the graph of a function since for $x = 0, \pm 1$, and ± 2 , there are infinitely many points on the curve.
9. The person's weight increased to about 160 pounds at age 20 and stayed fairly steady for 10 years. The person's weight dropped to about 120 pounds for the next 5 years, then increased rapidly to about 170 pounds. The next 30 years saw a gradual increase to 190 pounds. Possible reasons for the drop in weight at 30 years of age: diet, exercise, health problems.
10. The salesman travels away from home from 8 to 9 A.M. and is then stationary until 10:00. The salesman travels farther away from 10 until noon. There is no change in his distance from home until 1:00, at which time the distance from home decreases until 3:00. Then the distance starts increasing again, reaching the maximum distance away from home at 5:00. There is no change from 5 until 6, and then the distance decreases rapidly until 7:00 P.M., at which time the salesman reaches home.
11. The water will cool down almost to freezing as the ice melts. Then, when the ice has melted, the water will slowly warm up to room temperature.

12. The summer solstice (the longest day of the year) is around June 21, and the winter solstice (the shortest day) is around December 22.

13. Of course, this graph depends strongly on the geographical location!

14. The temperature of the pie would increase rapidly, level off to oven temperature, decrease rapidly, and then level off to room temperature.

15. Height of grass

16. (a)

- (b)

- (c)

- (d)

17. (a)

(b) From the graph, we estimate the number of cell-phone subscribers in Malaysia to be about 540 in 1994 and 1450 in 1996.

18. (a)

(b) From the graph in part (a), we estimate the temperature at 11:00 A.M. to be about 84.5°C .

19. $f(x) = 3x^2 - x + 2$.

$$f(2) = 3(2)^2 - 2 + 2 = 12 - 2 + 2 = 12.$$

$$f(-2) = 3(-2)^2 - (-2) + 2 = 12 + 2 + 2 = 16.$$

$$f(a) = 3a^2 - a + 2.$$

$$f(-a) = 3(-a)^2 - (-a) + 2 = 3a^2 + a + 2.$$

$$f(a+1) = 3(a+1)^2 - (a+1) + 2 = 3(a^2 + 2a + 1) - a - 1 + 2 = 3a^2 + 6a + 3 - a - 1 + 2 = 3a^2 + 5a + 4.$$

$$2f(a) = 2 \cdot f(a) = 2(3a^2 - a + 2) = 6a^2 - 2a + 4.$$

$$f(2a) = 3(2a)^2 - (2a) + 2 = 3(4a^2) - 2a + 2 = 12a^2 - 2a + 2.$$

$$f(a^2) = 3(a^2)^2 - (a^2) + 2 = 3(a^4) - a^2 + 2 = 3a^4 - a^2 + 2.$$

$$[f(a)]^2 = [3a^2 - a + 2]^2 = (3a^2 - a + 2)(3a^2 - a + 2)$$

$$= 9a^4 - 3a^3 + 6a^2 - 3a^3 + a^2 - 2a + 6a^2 - 2a + 4 = 9a^4 - 6a^3 + 13a^2 - 4a + 4.$$

$$f(a+h) = 3(a+h)^2 - (a+h) + 2 = 3(a^2 + 2ah + h^2) - a - h + 2 = 3a^2 + 6ah + 3h^2 - a - h + 2.$$

20. A spherical balloon with radius $r+1$ has volume $V(r+1) = \frac{4}{3}\pi(r+1)^3 = \frac{4}{3}\pi(r^3 + 3r^2 + 3r + 1)$. We wish to find the amount of air needed to inflate the balloon from a radius of r to $r+1$. Hence, we need to find the difference $V(r+1) - V(r) = \frac{4}{3}\pi(r^3 + 3r^2 + 3r + 1) - \frac{4}{3}\pi r^3 = \frac{4}{3}\pi(3r^2 + 3r + 1)$.

21. $f(x) = x - x^2$, so

$$f(2+h) = 2+h - (2+h)^2 = 2+h - (4+4h+h^2) = 2+h-4-4h-h^2 = -(h^2+3h+2),$$

$$f(x+h) = x+h - (x+h)^2 = x+h - (x^2+2xh+h^2) = x+h-x^2-2xh-h^2, \text{ and}$$

$$\frac{f(x+h) - f(x)}{h} = \frac{x+h-x^2-2xh-h^2-x+x^2}{h} = \frac{h-2xh-h^2}{h} = \frac{h(1-2x-h)}{h} = 1-2x-h.$$

22. $f(x) = \frac{x}{x+1}$, so $f(2+h) = \frac{2+h}{2+h+1} = \frac{2+h}{3+h}$, $f(x+h) = \frac{x+h}{x+h+1}$, and

$$\frac{f(x+h) - f(x)}{h} = \frac{\frac{x+h}{x+h+1} - \frac{x}{x+1}}{h} = \frac{(x+h)(x+1) - x(x+h+1)}{h(x+h+1)(x+1)} = \frac{1}{(x+h+1)(x+1)}.$$

23. $f(x) = x/(3x-1)$ is defined for all x except when $0 = 3x-1 \Leftrightarrow x = \frac{1}{3}$, so the domain is $\{x \in \mathbb{R} \mid x \neq \frac{1}{3}\} = (-\infty, \frac{1}{3}) \cup (\frac{1}{3}, \infty)$.

24. $f(x) = (5x+4)/(x^2+3x+2)$ is defined for all x except when $0 = x^2+3x+2 \Leftrightarrow 0 = (x+2)(x+1) \Leftrightarrow x = -2$ or -1 , so the domain is $\{x \in \mathbb{R} \mid x \neq -2, -1\} = (-\infty, -2) \cup (-2, -1) \cup (-1, \infty)$.

25. $f(t) = \sqrt{t} + \sqrt[3]{t}$ is defined when $t \geq 0$. These values of t give real number results for $\sqrt{t}$, whereas any value of t gives a real number result for $\sqrt[3]{t}$. The domain is $[0, \infty)$.

26. $g(u) = \sqrt{u} + \sqrt{4-u}$ is defined when $u \geq 0$ and $4-u \geq 0 \Leftrightarrow u \leq 4$. Thus, the domain is $0 \leq u \leq 4 = [0, 4]$.

27. $h(x) = 1/\sqrt[4]{x^2-5x}$ is defined when $x^2-5x > 0 \Leftrightarrow x(x-5) > 0$. Note that $x^2-5x \neq 0$ since that would result in division by zero. The expression $x(x-5)$ is positive if $x < 0$ or $x > 5$. (See Appendix A for methods for solving inequalities.) Thus, the domain is $(-\infty, 0) \cup (5, \infty)$.

28. $h(x) = \sqrt{4-x^2}$. Now $y = \sqrt{4-x^2} \Rightarrow y^2 = 4-x^2 \Leftrightarrow x^2+y^2 = 4$, so the graph is the top half of a circle of radius 2 with center at the origin. The domain is $\{x \mid 4-x^2 \geq 0\} = \{x \mid 4 \geq x^2\} = \{x \mid 2 \geq |x|\} = [-2, 2]$. From the graph, the range is $0 \leq y \leq 2$, or $[0, 2]$.

29. $f(x) = 5$ is defined for all real numbers, so the domain is $\mathbb{R}$, or $(-\infty, \infty)$. The graph of f is a horizontal line with y -intercept 5.

30. $F(x) = \frac{1}{2}(x+3)$ is defined for all real numbers, so the domain is $\mathbb{R}$, or $(-\infty, \infty)$. The graph of F is a line with x -intercept -3 and y -intercept $\frac{3}{2}$.

31. $f(t) = t^2 - 6t$ is defined for all real numbers, so the domain is $\mathbb{R}$, or $(-\infty, \infty)$. The graph of f is a parabola opening upward since the coefficient of t^2 is positive. To find the t -intercepts, let $y = 0$ and solve for t . $0 = t^2 - 6t = t(t-6) \Rightarrow t = 0$ and $t = 6$. The t -coordinate of the vertex is halfway between the t -intercepts, that is, at $t = 3$. Since $f(3) = 3^2 - 6 \cdot 3 = -9$, the vertex is $(3, -9)$.

6 □ CHAPTER 1 FUNCTIONS AND MODELS

32. $H(t) = \frac{4-t^2}{2-t} = \frac{(2+t)(2-t)}{2-t}$, so for $t \neq 2$, $H(t) = 2+t$. The domain is $\{t \mid t \neq 2\}$. So the graph of H is the same as the graph of the function $f(t) = t+2$ (a line) except for the hole at $(2, 4)$.

33. $g(x) = \sqrt{x-5}$ is defined when $x-5 \geq 0$ or $x \geq 5$, so the domain is $[5, \infty)$. Since $y = \sqrt{x-5} \Rightarrow y^2 = x-5 \Rightarrow x = y^2+5$, we see that g is the top half of a parabola.

$$34. F(x) = |2x+1| = \begin{cases} 2x+1 & \text{if } 2x+1 \geq 0 \\ -(2x+1) & \text{if } 2x+1 < 0 \end{cases}$$

$$= \begin{cases} 2x+1 & \text{if } x \geq -\frac{1}{2} \\ -2x-1 & \text{if } x < -\frac{1}{2} \end{cases}$$

The domain is $\mathbb{R}$, or $(-\infty, \infty)$.

35. $G(x) = \frac{3x+|x|}{x}$. Since $|x| = \begin{cases} x & \text{if } x \geq 0 \\ -x & \text{if } x < 0 \end{cases}$, we have

$$G(x) = \begin{cases} \frac{3x+x}{x} & \text{if } x > 0 \\ \frac{3x-x}{x} & \text{if } x < 0 \end{cases} = \begin{cases} \frac{4x}{x} & \text{if } x > 0 \\ \frac{2x}{x} & \text{if } x < 0 \end{cases} = \begin{cases} 4 & \text{if } x > 0 \\ 2 & \text{if } x < 0 \end{cases}$$

Note that G is not defined for $x = 0$. The domain is $(-\infty, 0) \cup (0, \infty)$.

36. $g(x) = \frac{|x|}{x^2}$. Since $|x| = \begin{cases} x & \text{if } x \geq 0 \\ -x & \text{if } x < 0 \end{cases}$, we have

$$g(x) = \begin{cases} \frac{x}{x^2} & \text{if } x > 0 \\ \frac{-x}{x^2} & \text{if } x < 0 \end{cases} = \begin{cases} \frac{1}{x} & \text{if } x > 0 \\ \frac{1}{-x} & \text{if } x < 0 \end{cases}$$

Note that g is not defined for $x = 0$. The domain is $(-\infty, 0) \cup (0, \infty)$.

37. $f(x) = \begin{cases} x & \text{if } x \leq 0 \\ x+1 & \text{if } x > 0 \end{cases}$

Domain is $\mathbb{R}$, or $(-\infty, \infty)$.

38. $f(x) = \begin{cases} 2x+3 & \text{if } x < -1 \\ 3-x & \text{if } x \geq -1 \end{cases}$

Domain is $\mathbb{R}$, or $(-\infty, \infty)$.

$$39. f(x) = \begin{cases} x+2 & \text{if } x \leq -1 \\ x^2 & \text{if } x > -1 \end{cases}$$

Note that for $x = -1$, both $x+2$ and x^2 are equal to 1. Domain is $\mathbb{R}$.

$$40. f(x) = \begin{cases} -1 & \text{if } x \leq -1 \\ 3x+2 & \text{if } -1 < x < 1 \\ 7-2x & \text{if } x \geq 1 \end{cases}$$

Domain is $\mathbb{R}$.

41. Recall that the slope m of a line between the two points (x_1, y_1) and (x_2, y_2) is $m = \frac{y_2 - y_1}{x_2 - x_1}$ and an equation of the line connecting those two points is $y - y_1 = m(x - x_1)$. The slope of this line segment is $\frac{-6 - 1}{4 - (-2)} = -\frac{7}{6}$, so an equation is $y - 1 = -\frac{7}{6}(x + 2)$. The function is $f(x) = -\frac{7}{6}x - \frac{4}{3}$, $-2 \leq x \leq 4$.
42. The slope of this line segment is $\frac{3 - (-2)}{6 - (-3)} = \frac{5}{9}$, so an equation is $y + 2 = \frac{5}{9}(x + 3)$. The function is $f(x) = \frac{5}{9}x - \frac{1}{3}$, $-3 \leq x \leq 6$.
43. We need to solve the given equation for y . $x + (y - 1)^2 = 0 \Leftrightarrow (y - 1)^2 = -x \Leftrightarrow y - 1 = \pm\sqrt{-x} \Leftrightarrow y = 1 \pm \sqrt{-x}$. The expression with the positive radical represents the top half of the parabola, and the one with the negative radical represents the bottom half. Hence, we want $f(x) = 1 - \sqrt{-x}$. Note that the domain is $x \leq 0$.
44. $(x - 1)^2 + y^2 = 1 \Leftrightarrow y = \pm\sqrt{1 - (x - 1)^2} = \pm\sqrt{2x - x^2}$. The top half is given by the function $f(x) = \sqrt{2x - x^2}$, $0 \leq x \leq 2$.
45. For $-1 \leq x \leq 2$, the graph is the line with slope 1 and y -intercept 1, that is, the line $y = x + 1$. For $2 < x \leq 4$, the graph is the line with slope $-\frac{3}{2}$ and x -intercept 4 [which corresponds to the point $(4, 0)$], so $y - 0 = -\frac{3}{2}(x - 4) = -\frac{3}{2}x + 6$. So the function is $f(x) = \begin{cases} x+1 & \text{if } -1 \leq x \leq 2 \\ -\frac{3}{2}x+6 & \text{if } 2 < x \leq 4 \end{cases}$
46. For $x \leq 0$, the graph is the line $y = 2$. For $0 < x \leq 1$, the graph is the line with slope -2 and y -intercept 2, that is, the line $y = -2x + 2$. For $x > 1$, the graph is the line with slope 1 and x -intercept 1, that is, the line $y = 1(x - 1) = x - 1$. So the function is $f(x) = \begin{cases} 2 & \text{if } x \leq 0 \\ -2x+2 & \text{if } 0 < x \leq 1 \\ x-1 & \text{if } 1 < x \end{cases}$
47. Let the length and width of the rectangle be L and W . Then the perimeter is $2L + 2W = 20$ and the area is $A = LW$. Solving the first equation for W in terms of L gives $W = \frac{20 - 2L}{2} = 10 - L$. Thus, $A(L) = L(10 - L) = 10L - L^2$. Since lengths are positive, the domain of A is $0 < L < 10$. If we further restrict L to be larger than W , then $5 < L < 10$ would be the domain.
48. Let the length and width of the rectangle be L and W . Then the area is $LW = 16$, so that $W = 16/L$. The perimeter is $P = 2L + 2W$, so $P(L) = 2L + 2(16/L) = 2L + 32/L$, and the domain of P is $L > 0$, since lengths must be positive quantities. If we further restrict L to be larger than W , then $L > 4$ would be the domain.

49. Let the length of a side of the equilateral triangle be x . Then by the Pythagorean Theorem, the height y of the triangle satisfies $y^2 + (\frac{1}{2}x)^2 = x^2$, so that $y^2 = x^2 - \frac{1}{4}x^2 = \frac{3}{4}x^2$ and $y = \frac{\sqrt{3}}{2}x$. Using the formula for the area A of a triangle, $A = \frac{1}{2}(\text{base})(\text{height})$, we obtain $A(x) = \frac{1}{2}(x)\left(\frac{\sqrt{3}}{2}x\right) = \frac{\sqrt{3}}{4}x^2$, with domain $x > 0$.
50. Let the volume of the cube be V and the length of an edge be L . Then $V = L^3$ so $L = \sqrt[3]{V}$, and the surface area is $S(V) = 6\left(\sqrt[3]{V}\right)^2 = 6V^{2/3}$, with domain $V > 0$.
51. Let each side of the base of the box have length x , and let the height of the box be h . Since the volume is 2, we know that $2 = hx^2$, so that $h = 2/x^2$, and the surface area is $S = x^2 + 4xh$. Thus, $S(x) = x^2 + 4x(2/x^2) = x^2 + (8/x)$, with domain $x > 0$.
52. The area of the window is $A = xh + \frac{1}{2}\pi\left(\frac{1}{2}x\right)^2 = xh + \frac{\pi x^2}{8}$, where h is the height of the rectangular portion of the window. The perimeter is $P = 2h + x + \frac{1}{2}\pi x = 30 \Leftrightarrow 2h = 30 - x - \frac{1}{2}\pi x \Leftrightarrow h = \frac{1}{4}(60 - 2x - \pi x)$. Thus,
- $$A(x) = x \frac{60 - 2x - \pi x}{4} + \frac{\pi x^2}{8} = 15x - \frac{1}{2}x^2 - \frac{\pi}{4}x^2 + \frac{\pi}{8}x^2 = 15x - \frac{4}{8}x^2 - \frac{\pi}{8}x^2 = 15x - x^2\left(\frac{\pi+4}{8}\right)$$
- Since the lengths x and h must be positive quantities, we have $x > 0$ and $h > 0$. For $h > 0$, we have $2h > 0 \Leftrightarrow 30 - x - \frac{1}{2}\pi x > 0 \Leftrightarrow 60 > 2x + \pi x \Leftrightarrow x < \frac{60}{2+\pi}$. Hence, the domain of A is $0 < x < \frac{60}{2+\pi}$.
53. The height of the box is x and the length and width are $L = 20 - 2x$, $W = 12 - 2x$. Then $V = LWx$ and so $V(x) = (20 - 2x)(12 - 2x)(x) = 4(10 - x)(6 - x)(x) = 4x(60 - 16x + x^2) = 4x^3 - 64x^2 + 240x$. The sides L , W , and x must be positive. Thus, $L > 0 \Leftrightarrow 20 - 2x > 0 \Leftrightarrow x < 10$; $W > 0 \Leftrightarrow 12 - 2x > 0 \Leftrightarrow x < 6$; and $x > 0$. Combining these restrictions gives us the domain $0 < x < 6$.

54.

$$C(x) = \begin{cases} \$2.00 & \text{if } 0.0 < x \leq 1.0 \\ 2.20 & \text{if } 1.0 < x \leq 1.1 \\ 2.40 & \text{if } 1.1 < x \leq 1.2 \\ 2.60 & \text{if } 1.2 < x \leq 1.3 \\ 2.80 & \text{if } 1.3 < x \leq 1.4 \\ 3.00 & \text{if } 1.4 < x \leq 1.5 \\ 3.20 & \text{if } 1.5 < x \leq 1.6 \\ 3.40 & \text{if } 1.6 < x \leq 1.7 \\ 3.60 & \text{if } 1.7 < x \leq 1.8 \\ 3.80 & \text{if } 1.8 < x \leq 1.9 \\ 4.00 & \text{if } 1.9 < x < 2.0 \end{cases}$$

55. (a)

(b) On \$14,000, tax is assessed on \$4000, and $10\%(\$4000) = \400 .

On \$26,000, tax is assessed on \$16,000, and

$$10\%(\$10,000) + 15\%(\$6000) = \$1000 + \$900 = \$1900.$$

- (c) As in part (b), there is \$1000 tax assessed on \$20,000 of income, so the graph of T is a line segment from $(10,000, 0)$ to $(20,000, 1000)$. The tax on \$30,000 is \$2500, so the graph of T for $x > 20,000$ is the ray with initial point $(20,000, 1000)$ that passes through $(30,000, 2500)$.

56. One example is the amount paid for cable or telephone system repair in the home, usually measured to the nearest quarter hour. Another example is the amount paid by a student in tuition fees, if the fees vary according to the number of credits for which the student has registered.
57. f is an odd function because its graph is symmetric about the origin. g is an even function because its graph is symmetric with respect to the y -axis.
58. f is not an even function since it is not symmetric with respect to the y -axis. f is not an odd function since it is not symmetric about the origin. Hence, f is *neither* even nor odd. g is an even function because its graph is symmetric with respect to the y -axis.
59. (a) Because an even function is symmetric with respect to the y -axis, and the point $(5, 3)$ is on the graph of this even function, the point $(-5, 3)$ must also be on its graph.
 (b) Because an odd function is symmetric with respect to the origin, and the point $(5, 3)$ is on the graph of this odd function, the point $(-5, -3)$ must also be on its graph.
60. (a) If f is even, we get the rest of the graph by reflecting about the y -axis. (b) If f is odd, we get the rest of the graph by rotating 180° about the origin.

61. $f(x) = x^{-2}$.

$$f(-x) = (-x)^{-2} = \frac{1}{(-x)^2} = \frac{1}{x^2} = x^{-2} = f(x)$$

So f is an even function.

62. $f(x) = x^{-3}$.

$$f(-x) = (-x)^{-3} = \frac{1}{(-x)^3} = \frac{1}{-x^3} = -\frac{1}{x^3} = -(x^{-3}) = -f(x)$$

So f is odd.

63. $f(x) = x^2 + x$, so $f(-x) = (-x)^2 + (-x) = x^2 - x$. Since this is neither $f(x)$ nor $-f(x)$, the function f is neither even nor odd.

64. $f(x) = x^4 - 4x^2$.

$$\begin{aligned} f(-x) &= (-x)^4 - 4(-x)^2 \\ &= x^4 - 4x^2 = f(x) \end{aligned}$$

So f is even.

65. $f(x) = x^3 - x$.

$$\begin{aligned} f(-x) &= (-x)^3 - (-x) = -x^3 + x \\ &= -(x^3 - x) = -f(x) \end{aligned}$$

So f is odd.

66. $f(x) = 3x^3 + 2x^2 + 1$, so $f(-x) = 3(-x)^3 + 2(-x)^2 + 1 = -3x^3 + 2x^2 + 1$. Since this is neither $f(x)$ nor $-f(x)$, the function f is neither even nor odd.

1.2 Mathematical Models: A Catalog of Essential Functions

- $f(x) = \sqrt[5]{x}$ is a root function with $n = 5$.
 - $g(x) = \sqrt{1-x^2}$ is an algebraic function because it is a root of a polynomial.
 - $h(x) = x^9 + x^4$ is a polynomial of degree 9.
 - $r(x) = \frac{x^2+1}{x^3+x}$ is a rational function because it is a ratio of polynomials.
 - $s(x) = \tan 2x$ is a trigonometric function.
 - $t(x) = \log_{10} x$ is a logarithmic function.
- $y = (x-6)/(x+6)$ is a rational function because it is a ratio of polynomials.
 - $y = x + x^2/\sqrt{x-1}$ is an algebraic function because it involves polynomials and roots of polynomials.
 - $y = 10^x$ is an exponential function (notice that x is the *exponent*).
 - $y = x^{10}$ is a power function (notice that x is the *base*).
 - $y = 2t^6 + t^4 - \pi$ is a polynomial of degree 6.
 - $y = \cos \theta + \sin \theta$ is a trigonometric function.
- We notice from the figure that g and h are even functions (symmetric with respect to the y -axis) and that f is an odd function (symmetric with respect to the origin). So (b) $[y = x^5]$ must be f . Since g is flatter than h near the origin, we must have (c) $[y = x^8]$ matched with g and (a) $[y = x^2]$ matched with h .
- The graph of $y = 3x$ is a line (choice G).
 - $y = 3^x$ is an exponential function (choice f).
 - $y = x^3$ is an odd polynomial function or power function (choice F).
 - $y = \sqrt[3]{x} = x^{1/3}$ is a root function (choice g).

5. (a) An equation for the family of linear functions with slope 2 is $y = f(x) = 2x + b$, where b is the y -intercept.

- (b) $f(2) = 1$ means that the point $(2, 1)$ is on the graph of f . We can use the point-slope form of a line to obtain an equation for the family of linear functions through the point $(2, 1)$. $y - 1 = m(x - 2)$, which is equivalent to $y = mx + (1 - 2m)$ in slope-intercept form.

- (c) To belong to both families, an equation must have slope $m = 2$, so the equation in part (b), $y = mx + (1 - 2m)$, becomes $y = 2x - 3$. It is the *only* function that belongs to both families.
6. All members of the family of linear functions $f(x) = 1 + m(x + 3)$ have graphs that are lines passing through the point $(-3, 1)$.

7. All members of the family of linear functions $f(x) = c - x$ have graphs that are lines with slope -1 . The y -intercept is c .

8. (a)

- (b) The slope of -4 means that for each increase of 1 dollar for a rental space, the number of spaces rented *decreases* by 4. The y -intercept of 200 is the number of spaces that would be occupied if there were no charge for each space. The x -intercept of 50 is the smallest rental fee that results in no spaces rented.

9. (a)

(b) The slope of $\frac{9}{5}$ means that F increases $\frac{9}{5}$ degrees for each increase of 1°C . (Equivalently, F increases by 9 when C increases by 5 and F decreases by 9 when C decreases by 5.) The F -intercept of 32 is the Fahrenheit temperature corresponding to a Celsius temperature of 0.

10. (a) Let d = distance traveled (in miles) and t = time elapsed (in hours). At $t = 0$, $d = 0$ and at $t = 50 \text{ minutes} = 50 \cdot \frac{1}{60} = \frac{5}{6} \text{ h}$, $d = 40$. Thus we have two points: $(0, 0)$ and $(\frac{5}{6}, 40)$, so

$$m = \frac{40 - 0}{\frac{5}{6} - 0} = 48 \text{ and so } d = 48t.$$

(c) The slope is 48 and represents the car's speed in mi/h.

11. (a) Using N in place of x and T in place of y , we find the slope to be $\frac{T_2 - T_1}{N_2 - N_1} = \frac{80 - 70}{173 - 113} = \frac{10}{60} = \frac{1}{6}$. So a linear equation is $T - 80 = \frac{1}{6}(N - 173) \Leftrightarrow T - 80 = \frac{1}{6}N - \frac{173}{6} \Leftrightarrow T = \frac{1}{6}N + \frac{307}{6} \left[\frac{307}{6} = 51.1\bar{6} \right]$.
- (b) The slope of $\frac{1}{6}$ means that the temperature in Fahrenheit degrees increases one-sixth as rapidly as the number of cricket chirps per minute. Said differently, each increase of 6 cricket chirps per minute corresponds to an increase of 1°F .
- (c) When $N = 150$, the temperature is given approximately by $T = \frac{1}{6}(150) + \frac{307}{6} = 76.1\bar{6}^\circ\text{F} \approx 76^\circ\text{F}$.

12. (a) Let x denote the number of chairs produced in one day and y the associated cost. Using the points $(100, 2200)$ and $(300, 4800)$ we get the slope $\frac{4800 - 2200}{300 - 100} = \frac{2600}{200} = 13$. So $y - 2200 = 13(x - 100) \Leftrightarrow y = 13x + 900$.

- (b) The slope of the line in part (a) is 13 and it represents the cost (in dollars) of producing each additional chair.
- (c) The y -intercept is 900 and it represents the fixed daily costs of operating the factory.

13. (a) We are given $\frac{\text{change in pressure}}{10 \text{ feet change in depth}} = \frac{4.34}{10} = 0.434$. Using P for pressure and d for depth with the point $(d, P) = (0, 15)$, we have the slope-intercept form of the line, $P = 0.434d + 15$.
- (b) When $P = 100$, then $100 = 0.434d + 15 \Leftrightarrow 0.434d = 85 \Leftrightarrow d = \frac{85}{0.434} \approx 195.85$ feet. Thus, the pressure is 100 lb/in^2 at a depth of approximately 196 feet.

14. (a) Using d in place of x and C in place of y , we find the slope to be

$$\frac{C_2 - C_1}{d_2 - d_1} = \frac{460 - 380}{800 - 480} = \frac{80}{320} = \frac{1}{4}$$

So a linear equation is $C - 460 = \frac{1}{4}(d - 800) \Leftrightarrow$

$$C - 460 = \frac{1}{4}d - 200 \Leftrightarrow C = \frac{1}{4}d + 260.$$

- (b) Letting $d = 1500$ we get $C = \frac{1}{4}(1500) + 260 = 635$.

The cost of driving 1500 miles is \$635.

- (d) The y -intercept represents the fixed cost, \$260.

- (e) A linear function gives a suitable model in this situation because you have fixed monthly costs such as insurance and car payments, as well as costs that increase as you drive, such as gasoline, oil, and tires, and the cost of these for each additional mile driven is a constant.

15. (a) The data appear to be periodic and a sine or cosine function would make the best model. A model of the form $f(x) = a \cos(bx) + c$ seems appropriate.

- (b) The data appear to be decreasing in a linear fashion. A model of the form $f(x) = mx + b$ seems appropriate.

16. (a) The data appear to be increasing exponentially. A model of the form $f(x) = a \cdot b^x$ or $f(x) = a \cdot b^x + c$ seems appropriate.

- (b) The data appear to be decreasing similarly to the values of the reciprocal function. A model of the form $f(x) = a/x$ seems appropriate.

Some values are given to many decimal places. These are the results given by several computer algebra systems—rounding is left to the reader.

17. (a)

A linear model does seem appropriate.

- (b) Using the points (4000, 14.1) and (60,000, 8.2), we obtain

$$y - 14.1 = \frac{8.2 - 14.1}{60,000 - 4000}(x - 4000) \text{ or, equivalently,}$$

$$y \approx -0.000105357x + 14.521429.$$

The slope of the line represents the cost per mile, \$0.25.

- (c) Using a computing device, we obtain the least squares regression line $y = -0.0000997855x + 13.950764$. The following commands and screens illustrate how to find the least squares regression line on a TI-83 Plus. Enter the data into list one (L1) and list two (L2). Press **STAT** **1** to enter the editor.

L1	L2	L3	1
4000	14.1		
6000	13		
8000	13.4		
12000	12.5		
16000	12		
20000	12.4		
30000	10.5		
L1 = {4000, 6000, 8...			

L1	L2	L3	2
12000	12.5		
16000	12		
20000	12.4		
30000	10.5		
45000	8.4		
60000	8.2		
L2(10) =			

Find the regression line and store it in Y_1 . Press **2nd** **QUIT** **STAT** **▸** **4** **VARS** **▸** **1** **1** **ENTER**.

LinReg(ax+b) Y_1	LinReg $y=ax+b$ $a=-9.978546E-5$ $b=13.95076408$	Plot1 Plot2 Plot3 Y_1 -9.978545618 $7893E-5X+13.9507$ 64077085 $Y_2=$ $Y_3=$ $Y_4=$ $Y_5=$
--------------------	---	---

Note from the last figure that the regression line has been stored in Y_1 and that Plot1 has been turned on (Plot1 is highlighted). You can turn on Plot1 from the Y= menu by placing the cursor on Plot1 and pressing **ENTER** or by pressing **2nd** **STAT PLOT** **1** **ENTER**.

2nd STAT PLOT 1 Plot1...On 2 Plot2...Off 3 Plot3...Off 4 PlotsOff	Plot2 Plot3 Off Off Type: $\square$ $\square$ $\square$ Xlist: L1 Ylist: L2 Mark: $\square$ +
---	--

Now press **ZOOM** **9** to produce a graph of the data and the regression line. Note that choice 9 of the ZOOM menu automatically selects a window that displays all of the data.

- (d) When $x = 25,000$, $y \approx 11.456$; or about 11.5 per 100 population.
 (e) When $x = 80,000$, $y \approx 5.968$; or about a 6% chance.
 (f) When $x = 200,000$, y is negative, so the model does not apply.

18. (a)

(b)

Using a computing device, we obtain the least squares regression line $y = 4.856x - 220.96$.

(c) When $x = 100^\circ \text{F}$, $y = 264.7 \approx 265$ chirps/min.

19. (a)

A linear model does seem appropriate.

(b)

Using a computing device, we obtain the least squares regression line $y = 0.089119747x - 158.2403249$, where x is the year and y is the height in feet.

(c) When $x = 2000$, the model gives $y \approx 20.00$ ft. Note that the actual winning height for the 2000 Olympics is *less than* the winning height for 1996—so much for that prediction.

(d) When $x = 2100$, $y \approx 28.91$ ft. This would be an increase of 9.49 ft from 1996 to 2100. Even though there was an increase of 8.59 ft from 1900 to 1996, it is unlikely that a similar increase will occur over the next 100 years.

20. By looking at the scatter plot of the data, we rule out the linear and logarithmic models.

We try various models:

Quadratic: $y = 0.496x^2 - 62.2893x + 1970.639$

Cubic: $y = 0.0201243201x^3 - 3.88037296x^2 + 247.6754468x - 5163.935198$

Quartic: $y = 0.0002951049x^4 - 0.0654560995x^3 + 5.27525641x^2 - 180.2266511x + 2203.210956$

Exponential: $y = 2.41422994(1.054516914)^x$

Power: $y = 0.000022854971x^{3.616078251}$

After examining the graphs of these models, we see that the cubic and quartic models are clearly the best.

21.

Using a computing device, we obtain the cubic function $y = ax^3 + bx^2 + cx + d$ with $a = 0.0012937$, $b = -7.06142$, $c = 12,823$, and $d = -7,743,770$. When $x = 1925$, $y \approx 1914$ (million).

22. (a) $T = 1.000396048d^{1.499661718}$

(b) The power model in part (a) is approximately $T = d^{1.5}$. Squaring both sides gives us $T^2 = d^3$, so the model matches Kepler's Third Law, $T^2 = kd^3$.

1.3 New Functions from Old Functions

- If the graph of f is shifted 3 units upward, its equation becomes $y = f(x) + 3$.
 - If the graph of f is shifted 3 units downward, its equation becomes $y = f(x) - 3$.
 - If the graph of f is shifted 3 units to the right, its equation becomes $y = f(x - 3)$.
 - If the graph of f is shifted 3 units to the left, its equation becomes $y = f(x + 3)$.
 - If the graph of f is reflected about the x -axis, its equation becomes $y = -f(x)$.
 - If the graph of f is reflected about the y -axis, its equation becomes $y = f(-x)$.
 - If the graph of f is stretched vertically by a factor of 3, its equation becomes $y = 3f(x)$.
 - If the graph of f is shrunk vertically by a factor of 3, its equation becomes $y = \frac{1}{3}f(x)$.
- To obtain the graph of $y = 5f(x)$ from the graph of $y = f(x)$, stretch the graph vertically by a factor of 5.
 - To obtain the graph of $y = f(x - 5)$ from the graph of $y = f(x)$, shift the graph 5 units to the right.
 - To obtain the graph of $y = -f(x)$ from the graph of $y = f(x)$, reflect the graph about the x -axis.

- (d) To obtain the graph of $y = -5f(x)$ from the graph of $y = f(x)$, stretch the graph vertically by a factor of 5 and reflect it about the x -axis.
- (e) To obtain the graph of $y = f(5x)$ from the graph of $y = f(x)$, shrink the graph horizontally by a factor of 5.
- (f) To obtain the graph of $y = 5f(x) - 3$ from the graph of $y = f(x)$, stretch the graph vertically by a factor of 5 and shift it 3 units downward.
3. (a) (graph 3) The graph of f is shifted 4 units to the right and has equation $y = f(x - 4)$.
- (b) (graph 1) The graph of f is shifted 3 units upward and has equation $y = f(x) + 3$.
- (c) (graph 4) The graph of f is shrunk vertically by a factor of 3 and has equation $y = \frac{1}{3}f(x)$.
- (d) (graph 5) The graph of f is shifted 4 units to the left and reflected about the x -axis. Its equation is $y = -f(x + 4)$.
- (e) (graph 2) The graph of f is shifted 6 units to the left and stretched vertically by a factor of 2. Its equation is $y = 2f(x + 6)$.

4. (a) To graph $y = f(x + 4)$ we shift the graph of f , 4 units to the left.

The point $(2, 1)$ on the graph of f corresponds to the point $(2 - 4, 1) = (-2, 1)$.

- (c) To graph $y = 2f(x)$ we stretch the graph of f vertically by a factor of 2.

The point $(2, 1)$ on the graph of f corresponds to the point $(2, 2 \cdot 1) = (2, 2)$.

- (b) To graph $y = f(x) + 4$ we shift the graph of f , 4 units upward.

The point $(2, 1)$ on the graph of f corresponds to the point $(2, 1 + 4) = (2, 5)$.

- (d) To graph $y = -\frac{1}{2}f(x) + 3$, we shrink the graph of f vertically by a factor of 2, then reflect the resulting graph about the x -axis, then shift the resulting graph 3 units upward.

The point $(2, 1)$ on the graph of f corresponds to the point $(2, -\frac{1}{2} \cdot 1 + 3) = (2, 2.5)$.

5. (a) To graph $y = f(2x)$ we shrink the graph of f horizontally by a factor of 2.

The point $(4, -1)$ on the graph of f corresponds to the point $(\frac{1}{2} \cdot 4, -1) = (2, -1)$.

- (c) To graph $y = f(-x)$ we reflect the graph of f about the y -axis.

The point $(4, -1)$ on the graph of f corresponds to the point $(-1 \cdot 4, -1) = (-4, -1)$.

- (b) To graph $y = f(\frac{1}{2}x)$ we stretch the graph of f horizontally by a factor of 2.

The point $(4, -1)$ on the graph of f corresponds to the point $(2 \cdot 4, -1) = (8, -1)$.

- (d) To graph $y = -f(-x)$ we reflect the graph of f about the y -axis, then about the x -axis.

The point $(4, -1)$ on the graph of f corresponds to the point $(-1 \cdot 4, -1 \cdot -1) = (-4, 1)$.

6. The graph of $y = f(x) = \sqrt{3x - x^2}$ has been shifted 2 units to the right and stretched vertically by a factor of 2. Thus, a function describing the graph is

$$\begin{aligned} y &= 2f(x - 2) = 2\sqrt{3(x - 2) - (x - 2)^2} \\ &= 2\sqrt{3x - 6 - (x^2 - 4x + 4)} = 2\sqrt{-x^2 + 7x - 10} \end{aligned}$$

7. The graph of $y = f(x) = \sqrt{3x - x^2}$ has been shifted 4 units to the left, reflected about the x -axis, and shifted downward 1 unit. Thus, a function describing the graph is

$$y = \underbrace{-1 \cdot}_{\text{reflect about } x\text{-axis}} \underbrace{f(x + 4)}_{\text{shift 4 units left}} \underbrace{- 1}_{\text{shift 1 unit down}}$$

This function can be written as

$$\begin{aligned} y &= -f(x + 4) - 1 = -\sqrt{3(x + 4) - (x + 4)^2} - 1 = -\sqrt{3x + 12 - (x^2 + 8x + 16)} - 1 \\ &= -\sqrt{-x^2 - 5x - 4} - 1 \end{aligned}$$

8. (a) The graph of $y = 2 \sin x$ can be obtained from the graph of $y = \sin x$ by stretching it vertically by a factor of 2.

- (b) The graph of $y = 1 + \sqrt{x}$ can be obtained from the graph of $y = \sqrt{x}$ by shifting it upward 1 unit.

9. $y = -x^3$: Start with the graph of $y = x^3$ and reflect about the x -axis. Note: Reflecting about the y -axis gives the same result since substituting $-x$ for x gives us $y = (-x)^3 = -x^3$.

10. $y = 1 - x^2 = -x^2 + 1$: Start with the graph of $y = x^2$, reflect about the x -axis, and then shift 1 unit upward.

11. $y = (x + 1)^2$: Start with the graph of $y = x^2$ and shift 1 unit to the left.

12. $y = x^2 - 4x + 3 = (x^2 - 4x + 4) - 1 = (x - 2)^2 - 1$: Start with the graph of $y = x^2$, shift 2 units to the right, and then shift 1 unit downward.

13. $y = 1 + 2 \cos x$: Start with the graph of $y = \cos x$, stretch vertically by a factor of 2, and then shift 1 unit upward.

14. $y = 4 \sin 3x$: Start with the graph of $y = \sin x$, compress horizontally by a factor of 3, and then stretch vertically by a factor of 4.

15. $y = \sin(x/2)$: Start with the graph of $y = \sin x$ and stretch horizontally by a factor of 2.

16. $y = 1/(x - 4)$: Start with the graph of $y = 1/x$ and shift 4 units to the right.

17. $y = \sqrt{x+3}$: Start with the graph of $y = \sqrt{x}$ and shift 3 units to the left.

18. $y = (x+2)^4 + 3$: Start with the graph of $y = x^4$, shift 2 units to the left, and then shift 3 units upward.

19. $y = \frac{1}{2}(x^2 + 8x) = \frac{1}{2}(x^2 + 8x + 16) - 8 = \frac{1}{2}(x+4)^2 - 8$: Start with the graph of $y = x^2$, compress vertically by a factor of 2, shift 4 units to the left, and then shift 8 units downward.

20. $y = 1 + \sqrt[3]{x-1}$: Start with the graph of $y = \sqrt[3]{x}$, shift 1 unit to the right, and then shift 1 unit upward.

21. $y = 2/(x+1)$: Start with the graph of $y = 1/x$, shift 1 unit to the left, and then stretch vertically by a factor of 2.

22. $y = \frac{1}{4} \tan(x - \frac{\pi}{4})$: Start with the graph of $y = \tan x$, shift $\frac{\pi}{4}$ units to the right, and then compress vertically by a factor of 4.

23. $y = |\sin x|$: Start with the graph of $y = \sin x$ and reflect all the parts of the graph below the x -axis about the x -axis.

24. $y = |x^2 - 2x| = |x^2 - 2x + 1 - 1| = |(x - 1)^2 - 1|$: Start with the graph of $y = x^2$, shift 1 unit right, shift 1 unit downward, and reflect the portion of the graph below the x -axis about the x -axis.

25. This is just like the solution to Example 4 except the amplitude of the curve (the 30°N curve in Figure 9 on June 21) is $14 - 12 = 2$. So the function is $L(t) = 12 + 2 \sin\left[\frac{2\pi}{365}(t - 80)\right]$. March 31 is the 90th day of the year, so the model gives $L(90) \approx 12.34$ h. The daylight time (5:51 A.M. to 6:18 P.M.) is 12 hours and 27 minutes, or 12.45 h. The model value differs from the actual value by $\frac{12.45 - 12.34}{12.45} \approx 0.009$, less than 1%.
26. Using a sine function to model the brightness of Delta Cephei as a function of time, we take its period to be 5.4 days, its amplitude to be 0.35 (on the scale of magnitude), and its average magnitude to be 4.0. If we take $t = 0$ at a time of average brightness, then the magnitude (brightness) as a function of time t in days can be modeled by the formula $M(t) = 4.0 + 0.35 \sin\left(\frac{2\pi}{5.4}t\right)$.
27. (a) To obtain $y = f(|x|)$, the portion of the graph of $y = f(x)$ to the right of the y -axis is reflected about the y -axis.

(b) $y = \sin |x|$

(c) $y = \sqrt{|x|}$

28. The most important features of the given graph are the x -intercepts and the maximum and minimum points. The graph of $y = 1/f(x)$ has vertical asymptotes at the x -values where there are x -intercepts on the graph of $y = f(x)$. The maximum of 1 on the graph of $y = f(x)$ corresponds to a minimum of $1/1 = 1$ on $y = 1/f(x)$. Similarly, the minimum on the graph of $y = f(x)$ corresponds to a maximum on the graph of $y = 1/f(x)$. As the values of y get large (positively or negatively) on the graph of $y = f(x)$, the values of y get close to zero on the graph of $y = 1/f(x)$.

29. Assuming that successive horizontal and vertical gridlines are a unit apart, we can make a table of approximate values as follows.

x	0	1	2	3	4	5	6
$f(x)$	2	1.7	1.3	1.0	0.7	0.3	0
$g(x)$	2	2.7	3	2.8	2.4	1.7	0
$f(x) + g(x)$	4	4.4	4.3	3.8	3.1	2.0	0

Connecting the points $(x, f(x) + g(x))$ with a smooth curve gives an approximation to the graph of $f + g$. Extra points can be plotted between those listed above if necessary.

30. First note that the domain of $f + g$ is the intersection of the domains of f and g ; that is, $f + g$ is only defined where both f and g are defined. Taking the horizontal and vertical units of length to be the distances between successive vertical and horizontal gridlines, we can make a table of approximate values as follows:

x	-2	-1	0	1	2	2.5	3
$f(x)$	-1	2.2	2.0	2.4	2.7	2.7	2.3
$g(x)$	1	-1.3	-1.2	-0.6	0.3	0.5	0.7
$f(x) + g(x)$	0	0.9	0.8	1.8	3.0	3.2	3.0

Extra values of x (like the value 2.5 in the table above) can be added as needed.

31. $f(x) = x^3 + 2x^2$; $g(x) = 3x^2 - 1$. $D = \mathbb{R}$ for both f and g .

$$(f + g)(x) = (x^3 + 2x^2) + (3x^2 - 1) = x^3 + 5x^2 - 1, \quad D = \mathbb{R}.$$

$$(f - g)(x) = (x^3 + 2x^2) - (3x^2 - 1) = x^3 - x^2 + 1, \quad D = \mathbb{R}.$$

$$(fg)(x) = (x^3 + 2x^2)(3x^2 - 1) = 3x^5 + 6x^4 - x^3 - 2x^2, \quad D = \mathbb{R}.$$

$$\left(\frac{f}{g}\right)(x) = \frac{x^3 + 2x^2}{3x^2 - 1}, \quad D = \left\{x \mid x \neq \pm \frac{1}{\sqrt{3}}\right\} \text{ since } 3x^2 - 1 \neq 0.$$

32. $f(x) = \sqrt{1+x}$, $D = [-1, \infty)$; $g(x) = \sqrt{1-x}$, $D = (-\infty, 1]$.

$$(f + g)(x) = \sqrt{1+x} + \sqrt{1-x}, \quad D = (-\infty, 1] \cap [-1, \infty) = [-1, 1].$$

$$(f - g)(x) = \sqrt{1+x} - \sqrt{1-x}, \quad D = [-1, 1].$$

$$(fg)(x) = \sqrt{1+x} \cdot \sqrt{1-x} = \sqrt{1-x^2}, \quad D = [-1, 1].$$

$$\left(\frac{f}{g}\right)(x) = \frac{\sqrt{1+x}}{\sqrt{1-x}}, \quad D = [-1, 1]. \text{ We must exclude } x = 1 \text{ since it would make } \frac{f}{g} \text{ undefined.}$$

33. $f(x) = x$, $g(x) = 1/x$

34. $f(x) = x^3$, $g(x) = -x^2$

35. $f(x) = 2x^2 - x$; $g(x) = 3x + 2$. $D = \mathbb{R}$ for both f and g , and hence for their composites.

$$(f \circ g)(x) = f(g(x)) = f(3x + 2) = 2(3x + 2)^2 - (3x + 2) = 2(9x^2 + 12x + 4) - 3x - 2 = 18x^2 + 21x + 6.$$

$$(g \circ f)(x) = g(f(x)) = g(2x^2 - x) = 3(2x^2 - x) + 2 = 6x^2 - 3x + 2.$$

$$(f \circ f)(x) = f(f(x)) = f(2x^2 - x) = 2(2x^2 - x)^2 - (2x^2 - x) = 2(4x^4 - 4x^3 + x^2) - 2x^2 + x = 8x^4 - 8x^3 + x.$$

$$(g \circ g)(x) = g(g(x)) = g(3x + 2) = 3(3x + 2) + 2 = 9x + 6 + 2 = 9x + 8.$$

36. $f(x) = 1 - x^3$, $D = \mathbb{R}$; $g(x) = 1/x$, $D = \{x \mid x \neq 0\}$.

$$(f \circ g)(x) = f(g(x)) = f(1/x) = 1 - (1/x)^3 = 1 - 1/x^3, \quad D = \{x \mid x \neq 0\}.$$

$$(g \circ f)(x) = g(f(x)) = g(1 - x^3) = 1/(1 - x^3), \quad D = \{x \mid 1 - x^3 \neq 0\} = \{x \mid x \neq 1\}.$$

$$(f \circ f)(x) = f(f(x)) = f(1 - x^3) = 1 - (1 - x^3)^3 = 1 - (1 - 3x^3 + 3x^6 - x^9) = x^9 - 3x^6 + 3x^3, \quad D = \mathbb{R}.$$

$$(g \circ g)(x) = g(g(x)) = g(1/x) = 1/(1/x) = x, \quad D = \{x \mid x \neq 0\} \text{ because } 0 \text{ is not in the domain of } g.$$

37. $f(x) = \sin x$, $D = \mathbb{R}$; $g(x) = 1 - \sqrt{x}$, $D = [0, \infty)$.

$$(f \circ g)(x) = f(g(x)) = f(1 - \sqrt{x}) = \sin(1 - \sqrt{x}), \quad D = [0, \infty).$$

$$(g \circ f)(x) = g(f(x)) = g(\sin x) = 1 - \sqrt{\sin x}. \text{ For } \sqrt{\sin x} \text{ to be defined, we must have}$$

$$\sin x \geq 0 \Leftrightarrow x \in [0, \pi] \cup [2\pi, 3\pi] \cup [-2\pi, -\pi] \cup [4\pi, 5\pi] \cup [-4\pi, -3\pi] \cup \dots, \text{ so}$$

$$D = \{x \mid x \in [2n\pi, \pi + 2n\pi], \text{ where } n \text{ is an integer}\}.$$

$$(f \circ f)(x) = f(f(x)) = f(\sin x) = \sin(\sin x), \quad D = \mathbb{R}.$$

$$(g \circ g)(x) = g(g(x)) = g(1 - \sqrt{x}) = 1 - \sqrt{1 - \sqrt{x}},$$

$$D = \{x \geq 0 \mid 1 - \sqrt{x} \geq 0\} = \{x \geq 0 \mid 1 \geq \sqrt{x}\} = \{x \geq 0 \mid \sqrt{x} \leq 1\} = [0, 1].$$

38. $f(x) = 1 - 3x, \quad D = \mathbb{R}; \quad g(x) = 5x^2 + 3x + 2, \quad D = \mathbb{R}.$

$$\begin{aligned}(f \circ g)(x) &= f(g(x)) = f(5x^2 + 3x + 2) = 1 - 3(5x^2 + 3x + 2) \\ &= 1 - 15x^2 - 9x - 6 = -15x^2 - 9x - 5, \quad D = \mathbb{R}.\end{aligned}$$

$$\begin{aligned}(g \circ f)(x) &= g(f(x)) = g(1 - 3x) = 5(1 - 3x)^2 + 3(1 - 3x) + 2 = 5(1 - 6x + 9x^2) + 3 - 9x + 2 \\ &= 5 - 30x + 45x^2 - 9x + 5 = 45x^2 - 39x + 10, \quad D = \mathbb{R}.\end{aligned}$$

$$(f \circ f)(x) = f(f(x)) = f(1 - 3x) = 1 - 3(1 - 3x) = 1 - 3 + 9x = 9x - 2, \quad D = \mathbb{R}.$$

$$\begin{aligned}(g \circ g)(x) &= g(g(x)) = g(5x^2 + 3x + 2) = 5(5x^2 + 3x + 2)^2 + 3(5x^2 + 3x + 2) + 2 \\ &= 5(25x^4 + 30x^3 + 29x^2 + 12x + 4) + 15x^2 + 9x + 6 + 2 \\ &= 125x^4 + 150x^3 + 145x^2 + 60x + 20 + 15x^2 + 9x + 8 \\ &= 125x^4 + 150x^3 + 160x^2 + 69x + 28, \quad D = \mathbb{R}.\end{aligned}$$

39. $f(x) = x + \frac{1}{x}, \quad D = \{x \mid x \neq 0\}; \quad g(x) = \frac{x+1}{x+2}, \quad D = \{x \mid x \neq -2\}.$

$$\begin{aligned}(f \circ g)(x) &= f(g(x)) = f\left(\frac{x+1}{x+2}\right) = \frac{x+1}{x+2} + \frac{1}{\frac{x+1}{x+2}} = \frac{x+1}{x+2} + \frac{x+2}{x+1} \\ &= \frac{(x+1)(x+1) + (x+2)(x+2)}{(x+2)(x+1)} = \frac{(x^2 + 2x + 1) + (x^2 + 4x + 4)}{(x+2)(x+1)} = \frac{2x^2 + 6x + 5}{(x+2)(x+1)}\end{aligned}$$

Since $g(x)$ is not defined for $x = -2$ and $f(g(x))$ is not defined for $x = -2$ and $x = -1$, the domain of $(f \circ g)(x)$ is $D = \{x \mid x \neq -2, -1\}.$

$$(g \circ f)(x) = g(f(x)) = g\left(x + \frac{1}{x}\right) = \frac{\left(x + \frac{1}{x}\right) + 1}{\left(x + \frac{1}{x}\right) + 2} = \frac{\frac{x^2 + 1 + x}{x}}{\frac{x^2 + 1 + 2x}{x}} = \frac{x^2 + x + 1}{x^2 + 2x + 1} = \frac{x^2 + x + 1}{(x+1)^2}.$$

Since $f(x)$ is not defined for $x = 0$ and $g(f(x))$ is not defined for $x = -1$, the domain of $(g \circ f)(x)$ is $D = \{x \mid x \neq -1, 0\}.$

$$\begin{aligned}(f \circ f)(x) &= f(f(x)) = f\left(x + \frac{1}{x}\right) = \left(x + \frac{1}{x}\right) + \frac{1}{x + \frac{1}{x}} = x + \frac{1}{x} + \frac{1}{\frac{x^2 + 1}{x}} = x + \frac{1}{x} + \frac{x}{x^2 + 1} \\ &= \frac{x(x)(x^2 + 1) + 1(x^2 + 1) + x(x)}{x(x^2 + 1)} = \frac{x^4 + x^2 + x^2 + 1 + x^2}{x(x^2 + 1)} \\ &= \frac{x^4 + 3x^2 + 1}{x(x^2 + 1)}, \quad D = \{x \mid x \neq 0\}.\end{aligned}$$

$$(g \circ g)(x) = g(g(x)) = g\left(\frac{x+1}{x+2}\right) = \frac{\frac{x+1}{x+2} + 1}{\frac{x+1}{x+2} + 2} = \frac{\frac{x+1+1(x+2)}{x+2}}{\frac{x+1+2(x+2)}{x+2}} = \frac{x+1+x+2}{x+1+2x+4} = \frac{2x+3}{3x+5}.$$

Since $g(x)$ is not defined for $x = -2$ and $g(g(x))$ is not defined for $x = -\frac{5}{3}$, the domain of $(g \circ g)(x)$ is $D = \{x \mid x \neq -2, -\frac{5}{3}\}.$

40. $f(x) = \sqrt{2x+3}$, $D = \{x \mid x \geq -\frac{3}{2}\}$; $g(x) = x^2 + 1$, $D = \mathbb{R}$.
 $(f \circ g)(x) = f(x^2 + 1) = \sqrt{2(x^2 + 1) + 3} = \sqrt{2x^2 + 5}$, $D = \mathbb{R}$.
 $(g \circ f)(x) = g(\sqrt{2x+3}) = (\sqrt{2x+3})^2 + 1 = (2x+3) + 1 = 2x+4$, $D = \{x \mid x \geq -\frac{3}{2}\}$.
 $(f \circ f)(x) = f(\sqrt{2x+3}) = \sqrt{2(\sqrt{2x+3}) + 3} = \sqrt{2\sqrt{2x+3} + 3}$, $D = \{x \mid x \geq -\frac{3}{2}\}$.
 $(g \circ g)(x) = g(x^2 + 1) = (x^2 + 1)^2 + 1 = (x^4 + 2x^2 + 1) + 1 = x^4 + 2x^2 + 2$, $D = \mathbb{R}$.
41. $(f \circ g \circ h)(x) = f(g(h(x))) = f(g(x-1)) = f(2(x-1))$
 $= 2(x-1) + 1 = 2x-1$
42. $(f \circ g \circ h)(x) = f(g(h(x))) = f(g(1-x)) = f((1-x)^2)$
 $= 2(1-x)^2 - 1 = 2x^2 - 4x + 1$
43. $(f \circ g \circ h)(x) = f(g(h(x))) = f(g(x+3)) = f((x+3)^2 + 2)$
 $= f(x^2 + 6x + 11) = \sqrt{(x^2 + 6x + 11) - 1} = \sqrt{x^2 + 6x + 10}$
44. $(f \circ g \circ h)(x) = f(g(h(x))) = f(g(\sqrt{x+3})) = f(\cos \sqrt{x+3}) = \frac{2}{\cos \sqrt{x+3} + 1}$
45. Let $g(x) = x^2 + 1$ and $f(x) = x^{10}$. Then $(f \circ g)(x) = f(g(x)) = (x^2 + 1)^{10} = F(x)$.
46. Let $g(x) = \sqrt{x}$ and $f(x) = \sin x$. Then $(f \circ g)(x) = f(g(x)) = \sin(\sqrt{x}) = F(x)$.
47. Let $g(x) = x^2$ and $f(x) = \frac{x}{x+4}$. Then $(f \circ g)(x) = f(g(x)) = \frac{x^2}{x^2+4} = G(x)$.
48. Let $g(x) = x+3$ and $f(x) = 1/x$. Then $(f \circ g)(x) = f(g(x)) = 1/(x+3) = G(x)$.
49. Let $g(t) = \cos t$ and $f(t) = \sqrt{t}$. Then $(f \circ g)(t) = f(g(t)) = \sqrt{\cos t} = u(t)$.
50. Let $g(t) = \tan t$ and $f(t) = \frac{t}{1+t}$. Then $(f \circ g)(t) = f(g(t)) = \frac{\tan t}{1+\tan t} = u(t)$.
51. Let $h(x) = x^2$, $g(x) = 3^x$, and $f(x) = 1-x$. Then $(f \circ g \circ h)(x) = 1-3^{x^2} = H(x)$.
52. Let $h(x) = \sqrt{x}$, $g(x) = x-1$, and $f(x) = \sqrt[3]{x}$. Then $(f \circ g \circ h)(x) = \sqrt[3]{\sqrt{x}-1} = H(x)$.
53. Let $h(x) = \sqrt{x}$, $g(x) = \sec x$, and $f(x) = x^4$. Then $(f \circ g \circ h)(x) = (\sec \sqrt{x})^4 = \sec^4(\sqrt{x}) = H(x)$.
54. (a) $f(g(1)) = f(6) = 5$ (b) $g(f(1)) = g(3) = 2$
(c) $f(f(1)) = f(3) = 4$ (d) $g(g(1)) = g(6) = 3$
(e) $(g \circ f)(3) = g(f(3)) = g(4) = 1$ (f) $(f \circ g)(6) = f(g(6)) = f(3) = 4$
55. (a) $g(2) = 5$, because the point $(2, 5)$ is on the graph of g . Thus, $f(g(2)) = f(5) = 4$, because the point $(5, 4)$ is on the graph of f .
(b) $g(f(0)) = g(0) = 3$
(c) $(f \circ g)(0) = f(g(0)) = f(3) = 0$
(d) $(g \circ f)(6) = g(f(6)) = g(6)$. This value is not defined, because there is no point on the graph of g that has x -coordinate 6.
(e) $(g \circ g)(-2) = g(g(-2)) = g(1) = 4$
(f) $(f \circ f)(4) = f(f(4)) = f(2) = -2$

56. To find a particular value of $f(g(x))$, say for $x = 0$, we note from the graph that $g(0) \approx 2.8$ and $f(2.8) \approx -0.5$. Thus, $f(g(0)) \approx f(2.8) \approx -0.5$. The other values listed in the table were obtained in a similar fashion.

x	$g(x)$	$f(g(x))$
-5	-0.2	-4
-4	1.2	-3.3
-3	2.2	-1.7
-2	2.8	-0.5
-1	3	-0.2

x	$g(x)$	$f(g(x))$
0	2.8	-0.5
1	2.2	-1.7
2	1.2	-3.3
3	-0.2	-4
4	-1.9	-2.2
5	-4.1	1.9

57. (a) Using the relationship $\text{distance} = \text{rate} \cdot \text{time}$ with the radius r as the distance, we have $r(t) = 60t$.
 (b) $A = \pi r^2 \Rightarrow (A \circ r)(t) = A(r(t)) = \pi(60t)^2 = 3600\pi t^2$. This formula gives us the extent of the rippled area (in cm^2) at any time t .
58. (a) $d = rt \Rightarrow d(t) = 350t$
 (b) There is a Pythagorean relationship involving the legs with lengths d and 1 and the hypotenuse with length s : $d^2 + 1^2 = s^2$. Thus, $s(d) = \sqrt{d^2 + 1}$.
 (c) $(s \circ d)(t) = s(d(t)) = s(350t) = \sqrt{(350t)^2 + 1}$

59. (a)

$$H(t) = \begin{cases} 0 & \text{if } t < 0 \\ 1 & \text{if } t \geq 0 \end{cases}$$

(b)

$$V(t) = \begin{cases} 0 & \text{if } t < 0 \\ 120 & \text{if } t \geq 0 \end{cases} \quad \text{so } V(t) = 120H(t).$$

(c)

Starting with the formula in part (b), we replace 120 with 240 to reflect the different voltage. Also, because we are starting 5 units to the right of $t = 0$, we replace t with $t - 5$. Thus, the formula is $V(t) = 240H(t - 5)$.

60. (a) $R(t) = tH(t)$

$$= \begin{cases} 0 & \text{if } t < 0 \\ t & \text{if } t \geq 0 \end{cases}$$

$$(b) \quad V(t) = \begin{cases} 0 & \text{if } t < 0 \\ 2t & \text{if } 0 \leq t \leq 60 \end{cases}$$

so $V(t) = 2tH(t), t \leq 60$.

$$(c) \quad V(t) = \begin{cases} 0 & \text{if } t < 7 \\ 4(t - 7) & \text{if } 7 \leq t \leq 32 \end{cases}$$

so $V(t) = 4(t - 7)H(t - 7), t \leq 32$.

61. (a) By examining the variable terms in g and h , we deduce that we must square g to get the terms $4x^2$ and $4x$ in h .
 If we let $f(x) = x^2 + c$, then $(f \circ g)(x) = f(g(x)) = f(2x + 1) = (2x + 1)^2 + c = 4x^2 + 4x + (1 + c)$.
 Since $h(x) = 4x^2 + 4x + 7$, we must have $1 + c = 7$. So $c = 6$ and $f(x) = x^2 + 6$.

(b) We need a function g so that $f(g(x)) = 3(g(x)) + 5 = h(x)$. But

$$h(x) = 3x^2 + 3x + 2 = 3(x^2 + x) + 2 = 3(x^2 + x - 1) + 5, \text{ so we see that } g(x) = x^2 + x - 1.$$

62. We need a function g so that $g(f(x)) = g(x + 4) = h(x) = 4x - 1 = 4(x + 4) - 17$. So we see that the function g must be $g(x) = 4x - 17$.

63. We need to examine $h(-x)$.

$$h(-x) = (f \circ g)(-x) = f(g(-x)) = f(g(x)) \quad [\text{because } g \text{ is even}] = h(x)$$

Because $h(-x) = h(x)$, h is an even function.

64. $h(-x) = f(g(-x)) = f(-g(x))$. At this point, we can't simplify the expression, so we might try to find a counterexample to show that h is not an odd function. Let $g(x) = x$, an odd function, and $f(x) = x^2 + x$. Then $h(x) = x^2 + x$, which is neither even nor odd.

Now suppose f is an odd function. Then $f(-g(x)) = -f(g(x)) = -h(x)$. Hence, $h(-x) = -h(x)$, and so h is odd if both f and g are odd.

Now suppose f is an even function. Then $f(-g(x)) = f(g(x)) = h(x)$. Hence, $h(-x) = h(x)$, and so h is even if g is odd and f is even.

1.4 Graphing Calculators and Computers

1. $f(x) = x^4 + 2$

(a) $[-2, 2]$ by $[-2, 2]$

(b) $[0, 4]$ by $[0, 4]$

(c) $[-4, 4]$ by $[-4, 4]$

(d) $[-8, 8]$ by $[-4, 40]$

(e) $[-40, 40]$ by $[-80, 800]$

The most appropriate graph is produced in viewing rectangle (d).

2. $f(x) = x^2 + 7x + 6$

(a) $[-5, 5]$ by $[-5, 5]$

(b) $[0, 10]$ by $[-20, 100]$

(c) $[-15, 8]$ by $[-20, 100]$

(d) $[-10, 3]$ by $[-100, 20]$

The most appropriate graph is produced in viewing rectangle (c).

3. $f(x) = 10 + 25x - x^3$

(a) $[-4, 4]$ by $[-4, 4]$

(b) $[-10, 10]$ by $[-10, 10]$

(c) $[-20, 20]$ by $[-100, 100]$

(d) $[-100, 100]$ by $[-200, 200]$

The most appropriate graph is produced in viewing rectangle (c) because the maximum and minimum points are fairly easy to see and estimate.

4. $f(x) = \sqrt{8x - x^2}$

(a) $[-4, 4]$ by $[-4, 4]$

(b) $[-5, 5]$ by $[0, 100]$

(c) $[-10, 10]$ by $[-10, 40]$

(d) $[-2, 10]$ by $[-2, 6]$

The most appropriate graph is produced in viewing rectangle (d).

5. Since the graph of $f(x) = 5 + 20x - x^2$ is a parabola opening downward, an appropriate viewing rectangle should include the maximum point.

6. An appropriate viewing rectangle for $f(x) = x^3 + 30x^2 + 200x$ should include the high and low points.

7. $f(x) = 0.01x^3 - x^2 + 5$. Graphing f in a standard viewing rectangle, $[-10, 10]$ by $[-10, 10]$, shows us what appears to be a parabola. But since this is a cubic polynomial, we know that a larger viewing rectangle will reveal a minimum point as well as the maximum point. After some trial and error, we choose the viewing rectangle $[-50, 150]$ by $[-2000, 2000]$.

8. $f(x) = x(x+6)(x-9)$

9. $f(x) = \sqrt[4]{81 - x^4}$ is defined when

$$81 - x^4 \geq 0 \Leftrightarrow x^4 \leq 81 \Leftrightarrow |x| \leq 3, \text{ so}$$

the domain of f is $[-3, 3]$. Also

$$0 \leq \sqrt[4]{81 - x^4} \leq \sqrt[4]{81} = 3, \text{ so the range is } [0, 3].$$

10. $f(x) = \sqrt{0.1x + 20}$ is defined when

$$0.1x + 20 \geq 0 \Leftrightarrow x \geq -200, \text{ so the domain of } f \text{ is } [-200, \infty).$$

11. The graph of $f(x) = x^2 + (100/x)$ has a vertical asymptote of $x = 0$. As you zoom out, the graph of f looks more and more like that of $y = x^2$.

12. The graph of $f(x) = x/(x^2 + 100)$ is symmetric with respect to the origin.

13. $f(x) = \cos(100x)$

14. $f(x) = 3 \sin(120x)$

15. $f(x) = \sin(x/40)$

16. $f(x) = \tan(25x)$

17. $y = 3^{\cos(x^2)}$

18. $y = x^2 + 0.02 \sin(50x)$

19. We must solve the given equation for y to obtain equations for the upper and lower halves of the ellipse.

$$4x^2 + 2y^2 = 1 \Leftrightarrow 2y^2 = 1 - 4x^2 \Leftrightarrow y^2 = \frac{1 - 4x^2}{2}$$

$$\Leftrightarrow y = \pm \sqrt{\frac{1 - 4x^2}{2}}$$

20. $y^2 - 9x^2 = 1 \Leftrightarrow y^2 = 1 + 9x^2 \Leftrightarrow y = \pm \sqrt{1 + 9x^2}$

21. From the graph of $f(x) = x^3 - 9x^2 - 4$, we see that there is one solution of the equation $f(x) = 0$ and it is slightly larger than 9. By zooming in or using a root or zero feature, we obtain $x \approx 9.05$.

22. We see that the graphs of $f(x) = x^3$ and $g(x) = 4x - 1$ intersect three times. The x -coordinates of these points (which are the solutions of the equation) are approximately -2.11 , 0.25 , and 1.86 . Alternatively, we could find these values by finding the zeros of $h(x) = x^3 - 4x + 1$.

23. We see that the graphs of $f(x) = x^2$ and $g(x) = \sin x$ intersect twice. One solution is $x = 0$. The other solution of $f = g$ is the x -coordinate of the point of intersection in the first quadrant. Using an intersect feature or zooming in, we find this value to be approximately 0.88. Alternatively, we could find that value by finding the positive zero of $h(x) = x^2 - \sin x$.

Note: After producing the graph on a TI-83 Plus, we can find the approximate value 0.88 by using the following keystrokes: **2nd** **CALC** **5** **ENTER** **ENTER** **1** **ENTER**. The “1” is just a guess for 0.88.

24. (a)

The x -coordinates of the three points of intersection are $x \approx -3.29, -2.36$ and 1.20 .

(b) Using trial and error, we find that $m \approx 0.3365$. Note that m could also be negative.

25. $g(x) = x^3/10$ is larger than $f(x) = 10x^2$ whenever $x > 100$.

26. $f(x) = x^4 - 100x^3$ is larger than $g(x) = x^3$ whenever $x > 101$.

34 □ CHAPTER 1 FUNCTIONS AND MODELS

27.

We see from the graphs of $y = |\sin x - x|$ and $y = 0.1$ that there are two solutions to the equation $|\sin x - x| = 0.1$: $x \approx -0.85$ and $x \approx 0.85$. The condition $|\sin x - x| < 0.1$ holds for any x lying between these two values.

28.

$P(x) = 3x^5 - 5x^3 + 2x$,
 $Q(x) = 3x^5$. These graphs are significantly different only in the region close to the origin. The larger a viewing rectangle one chooses, the more similar the two graphs look.

29. (a) The root functions $y = \sqrt{x}$,
 $y = \sqrt[4]{x}$ and $y = \sqrt[6]{x}$

(b) The root functions $y = x$,
 $y = \sqrt[3]{x}$ and $y = \sqrt[5]{x}$

(c) The root functions $y = \sqrt{x}$,
 $y = \sqrt[3]{x}$, $y = \sqrt[4]{x}$ and $y = \sqrt[5]{x}$

- (d) • For any n , the n th root of 0 is 0 and the n th root of 1 is 1; that is, all n th root functions pass through the points $(0, 0)$ and $(1, 1)$.
- For odd n , the domain of the n th root function is $\mathbb{R}$, while for even n , it is $\{x \in \mathbb{R} \mid x \geq 0\}$.
- Graphs of even root functions look similar to that of $\sqrt{x}$, while those of odd root functions resemble that of $\sqrt[3]{x}$.
- As n increases, the graph of $\sqrt[n]{x}$ becomes steeper near 0 and flatter for $x > 1$.

30. (a) The functions $y = 1/x$ and
 $y = 1/x^3$

(b) The functions $y = 1/x^2$
and $y = 1/x^4$

(c) The functions $y = 1/x$, $y = 1/x^2$,
 $y = 1/x^3$ and $y = 1/x^4$

- (d) • The graphs of all functions of the form $y = 1/x^n$ pass through the point $(1, 1)$.
- If n is even, the graph of the function is entirely above the x -axis. The graphs of $1/x^n$ for n even are similar to one another.
 - If n is odd, the function is positive for positive x and negative for negative x . The graphs of $1/x^n$ for n odd are similar to one another.
 - As n increases, the graphs of $1/x^n$ approach 0 faster as $x \rightarrow \infty$.

31. $f(x) = x^4 + cx^2 + x$. If $c < 0$, there are three humps: two minimum points and a maximum point. These humps get flatter as c increases, until at $c = 0$ two of the humps disappear and there is only one minimum point. This single hump then moves to the right and approaches the origin as c increases.

32. $f(x) = \sqrt{1 + cx^2}$. If $c < 0$, the function is only defined on $[-1/\sqrt{-c}, 1/\sqrt{-c}]$, and its graph is the top half of an ellipse. If $c = 0$, the graph is the line $y = 1$. If $c > 0$, the graph is the top half of a hyperbola. As c approaches 0, these curves become flatter and approach the line $y = 1$.

33. $y = x^n 2^{-x}$. As n increases, the maximum of the function moves further from the origin, and gets larger. Note, however, that regardless of n , the function approaches 0 as $x \rightarrow \infty$.

34. $y = \frac{|x|}{\sqrt{c - x^2}}$. The “bullet” becomes broader as c increases.

35. $y^2 = cx^3 + x^2$

If $c < 0$, the loop is to the right of the origin, and if c is positive, it is to the left. In both cases, the closer c is to 0, the larger the loop is. (In the limiting case, $c = 0$, the loop is “infinite”, that is, it doesn’t close.) Also, the larger $|c|$ is, the steeper the slope is on the loopless side of the origin.

36. (a) $y = \sin(\sqrt{x})$

This function is not periodic; it oscillates less frequently as x increases.

(b) $y = \sin(x^2)$

This function oscillates more frequently as $|x|$ increases. Note also that this function is even, whereas $\sin x$ is odd.

37. The graphing window is 95 pixels wide and we want to start with $x = 0$ and end with $x = 2\pi$. Since there are 94 “gaps” between pixels, the distance between pixels is $\frac{2\pi-0}{94}$. Thus, the x -values that the calculator actually plots are $x = 0 + \frac{2\pi}{94} \cdot n$, where $n = 0, 1, 2, \dots, 93, 94$. For $y = \sin 2x$, the actual points plotted by the calculator are $(\frac{2\pi}{94} \cdot n, \sin(2 \cdot \frac{2\pi}{94} \cdot n))$ for $n = 0, 1, \dots, 94$. For $y = \sin 96x$, the points plotted are $(\frac{2\pi}{94} \cdot n, \sin(96 \cdot \frac{2\pi}{94} \cdot n))$ for $n = 0, 1, \dots, 94$. But

$$\begin{aligned}\sin(96 \cdot \frac{2\pi}{94} \cdot n) &= \sin(94 \cdot \frac{2\pi}{94} \cdot n + 2 \cdot \frac{2\pi}{94} \cdot n) = \sin(2\pi n + 2 \cdot \frac{2\pi}{94} \cdot n) \\ &= \sin(2 \cdot \frac{2\pi}{94} \cdot n) \quad [\text{by periodicity of sine}], \quad n = 0, 1, \dots, 94\end{aligned}$$

So the y -values, and hence the points, plotted for $y = \sin 96x$ are identical to those plotted for $y = \sin 2x$.

Note: Try graphing $y = \sin 94x$. Can you see why all the y -values are zero?

38. As in Exercise 37, we know that the points being plotted for $y = \sin 45x$ are $(\frac{2\pi}{94} \cdot n, \sin(45 \cdot \frac{2\pi}{94} \cdot n))$ for $n = 0, 1, \dots, 94$. But

$$\begin{aligned}\sin(45 \cdot \frac{2\pi}{94} \cdot n) &= \sin(47 \cdot \frac{2\pi}{94} \cdot n - 2 \cdot \frac{2\pi}{94} \cdot n) = \sin(n\pi - 2 \cdot \frac{2\pi}{94} \cdot n) \\ &= \sin(n\pi) \cos(2 \cdot \frac{2\pi}{94} \cdot n) - \cos(n\pi) \sin(2 \cdot \frac{2\pi}{94} \cdot n) \quad [\text{Subtraction formula for the sine}] \\ &= 0 \cdot \cos(2 \cdot \frac{2\pi}{94} \cdot n) - (\pm 1) \sin(2 \cdot \frac{2\pi}{94} \cdot n) = \pm \sin(2 \cdot \frac{2\pi}{94} \cdot n), \quad n = 0, 1, \dots, 94\end{aligned}$$

So the y -values, and hence the points, plotted for $y = \sin 45x$ lie on either $y = \sin 2x$ or $y = -\sin 2x$.

1 Review

CONCEPT CHECK

- (a) A **function** f is a rule that assigns to each element x in a set A exactly one element, called $f(x)$, in a set B . The set A is called the **domain** of the function. The **range** of f is the set of all possible values of $f(x)$ as x varies throughout the domain.
(b) If f is a function with domain A , then its **graph** is the set of ordered pairs $\{(x, f(x)) \mid x \in A\}$.
(c) Use the Vertical Line Test on page 17.
- The four ways to represent a function are: verbally, numerically, visually, and algebraically. An example of each is given below.

Verbally: An assignment of students to chairs in a classroom (a description in words)

Numerically: A tax table that assigns an amount of tax to an income (a table of values)

Visually: A graphical history of the Dow Jones average (a graph)

Algebraically: A relationship between distance, rate, and time: $d = rt$ (an explicit formula)

3. (a) An **even function** f satisfies $f(-x) = f(x)$ for every number x in its domain. It is symmetric with respect to the y -axis.
- (b) An **odd function** g satisfies $g(-x) = -g(x)$ for every number x in its domain. It is symmetric with respect to the origin.
4. A function f is called **increasing** on an interval I if $f(x_1) < f(x_2)$ whenever $x_1 < x_2$ in I .
5. A **mathematical model** is a mathematical description (often by means of a function or an equation) of a real-world phenomenon.
6. (a) Linear function: $f(x) = 2x + 1$, $f(x) = ax + b$
- (b) Power function: $f(x) = x^2$, $f(x) = x^a$
- (c) Exponential function: $f(x) = 2^x$, $f(x) = a^x$
- (d) Quadratic function: $f(x) = x^2 + x + 1$,
 $f(x) = ax^2 + bx + c$
- (e) Polynomial of degree 5: $f(x) = x^5 + 2$
- (f) Rational function: $f(x) = \frac{x}{x+2}$, $f(x) = \frac{P(x)}{Q(x)}$ where
 $P(x)$ and $Q(x)$ are polynomials

9. (a) The domain of $f + g$ is the intersection of the domain of f and the domain of g ; that is, $A \cap B$.
- (b) The domain of fg is also $A \cap B$.
- (c) The domain of f/g must exclude values of x that make g equal to 0; that is, $\{x \in A \cap B \mid g(x) \neq 0\}$.
10. Given two functions f and g , the **composite function** $f \circ g$ is defined by $(f \circ g)(x) = f(g(x))$. The domain of $f \circ g$ is the set of all x in the domain of g such that $g(x)$ is in the domain of f .
11. (a) If the graph of f is shifted 2 units upward, its equation becomes $y = f(x) + 2$.
- (b) If the graph of f is shifted 2 units downward, its equation becomes $y = f(x) - 2$.
- (c) If the graph of f is shifted 2 units to the right, its equation becomes $y = f(x - 2)$.
- (d) If the graph of f is shifted 2 units to the left, its equation becomes $y = f(x + 2)$.

- (e) If the graph of f is reflected about the x -axis, its equation becomes $y = -f(x)$.
 (f) If the graph of f is reflected about the y -axis, its equation becomes $y = f(-x)$.
 (g) If the graph of f is stretched vertically by a factor of 2, its equation becomes $y = 2f(x)$.
 (h) If the graph of f is shrunk vertically by a factor of 2, its equation becomes $y = \frac{1}{2}f(x)$.
 (i) If the graph of f is stretched horizontally by a factor of 2, its equation becomes $y = f(\frac{1}{2}x)$.
 (j) If the graph of f is shrunk horizontally by a factor of 2, its equation becomes $y = f(2x)$.

TRUE-FALSE QUIZ

- False. Let $f(x) = x^2$, $s = -1$, and $t = 1$. Then $f(s + t) = (-1 + 1)^2 = 0^2 = 0$, but $f(s) + f(t) = (-1)^2 + 1^2 = 2 \neq 0 = f(s + t)$.
- False. Let $f(x) = x^2$. Then $f(-2) = 4 = f(2)$, but $-2 \neq 2$.
- False. Let $f(x) = x^2$. Then $f(3x) = (3x)^2 = 9x^2$ and $3f(x) = 3x^2$. So $f(3x) \neq 3f(x)$.
- True. If $x_1 < x_2$ and f is a decreasing function, then the y -values get smaller as we move from left to right. Thus, $f(x_1) > f(x_2)$.
- True. See the Vertical Line Test.
- False. Let $f(x) = x^2$ and $g(x) = 2x$. Then $(f \circ g)(x) = f(g(x)) = f(2x) = (2x)^2 = 4x^2$ and $(g \circ f)(x) = g(f(x)) = g(x^2) = 2x^2$. So $f \circ g \neq g \circ f$.

EXERCISES

- When $x = 2$, $y \approx 2.7$. Thus, $f(2) \approx 2.7$.
 - $f(x) = 3 \Rightarrow x \approx 2.3, 5.6$
 - The domain of f is $-6 \leq x \leq 6$, or $[-6, 6]$.
 - The range of f is $-4 \leq y \leq 4$, or $[-4, 4]$.
 - f is increasing on $[-4, 4]$, that is, on $-4 \leq x \leq 4$.
 - f is odd since its graph is symmetric about the origin.
- This curve is *not* the graph of a function of x since it *fails* the Vertical Line Test.
 - This curve *is* the graph of a function of x since it *passes* the Vertical Line Test. The domain is $[-3, 3]$ and the range is $[-2, 3]$.

3. (a)

- (b) From the graph, we see that the distance traveled after 4.5 seconds is slightly less than 150 feet.

4.

There will be some yield with no fertilizer, increasing yields with increasing fertilizer use, a leveling-off of yields at some point, and disaster with too much fertilizer use.

5. $f(x) = \sqrt{4 - 3x^2}$. Domain: $4 - 3x^2 \geq 0 \Rightarrow 3x^2 \leq 4 \Rightarrow x^2 \leq \frac{4}{3} \Rightarrow |x| \leq \frac{2}{\sqrt{3}}$. Range: $y \geq 0$ and $y \leq \sqrt{4} \Rightarrow 0 \leq y \leq 2$.
6. $g(x) = \frac{1}{x+1}$. Domain: $x+1 \neq 0 \Rightarrow x \neq -1$. Range: all reals except 0 ($y = 0$ is the horizontal asymptote for g .)
7. $y = 1 + \sin x$. Domain: $\mathbb{R}$. Range: $-1 \leq \sin x \leq 1 \Rightarrow 0 \leq 1 + \sin x \leq 2 \Rightarrow 0 \leq y \leq 2$.
8. $y = \tan 2x$. Domain: $2x \neq \frac{\pi}{2} + \pi n \Rightarrow x \neq \frac{\pi}{4} + \frac{\pi}{2}n$. Range: the tangent function takes on all real values, so the range is $\mathbb{R}$.
9. (a) To obtain the graph of $y = f(x) + 8$, we shift the graph of $y = f(x)$ up 8 units.
 (b) To obtain the graph of $y = f(x + 8)$, we shift the graph of $y = f(x)$ left 8 units.
 (c) To obtain the graph of $y = 1 + 2f(x)$, we stretch the graph of $y = f(x)$ vertically by a factor of 2, and then shift the resulting graph 1 unit upward.
 (d) To obtain the graph of $y = f(x - 2) - 2$, we shift the graph of $y = f(x)$ right 2 units (for the “-2” inside the parentheses), and then shift the resulting graph 2 units downward.
 (e) To obtain the graph of $y = -f(x)$, we reflect the graph of $y = f(x)$ about the x -axis.
 (f) To obtain the graph of $y = 3 - f(x)$, we reflect the graph of $y = f(x)$ about the x -axis, and then shift the resulting graph 3 units upward.

10. (a) To obtain the graph of $y = f(x - 8)$, we shift the graph of $y = f(x)$ right 8 units.

- (b) To obtain the graph of $y = -f(x)$, we reflect the graph of $y = f(x)$ about the x -axis.

- (c) To obtain the graph of $y = 2 - f(x)$, we reflect the graph of $y = f(x)$ about the x -axis, and then shift the resulting graph 2 units upward.

- (d) To obtain the graph of $y = \frac{1}{2}f(x) - 1$, we shrink the graph of $y = f(x)$ by a factor of 2, and then shift the resulting graph 1 unit downward.

11. $y = -\sin 2x$: Start with the graph of $y = \sin x$, compress horizontally by a factor of 2, and reflect about the x -axis.

12. $y = (x - 2)^2$: Start with the graph of $y = x^2$ and shift 2 units to the right.

13. $y = 1 + \frac{1}{2}x^3$: Start with the graph of $y = x^3$, compress vertically by a factor of 2, and shift 1 unit upward.

14. $y = 2 - \sqrt{x}$: Start with the graph of $y = \sqrt{x}$, reflect about the x -axis, and shift 2 units upward.

15. $f(x) = \frac{1}{x+2}$: Start with the graph of $f(x) = 1/x$ and shift 2 units to the left.

$$16. f(x) = \begin{cases} 1+x & \text{if } x < 0 \\ 1+x^2 & \text{if } x \geq 0 \end{cases}$$

On $(-\infty, 0)$, graph $y = 1 + x$ (the line with slope 1 and y -intercept 1) with open endpoint $(0, 1)$.

On $[0, \infty)$, graph $y = 1 + x^2$ (the rightmost half of the parabola $y = x^2$ shifted 1 unit upward) with closed endpoint $(0, 1)$.

17. (a) The terms of f are a mixture of odd and even powers of x , so f is neither even nor odd.
 (b) The terms of f are all odd powers of x , so f is odd.
 (c) $f(-x) = \cos((-x)^2) = \cos(x^2) = f(x)$, so f is even.
 (d) $f(-x) = 1 + \sin(-x) = 1 - \sin x$. Now $f(-x) \neq f(x)$ and $f(-x) \neq -f(x)$, so f is neither even nor odd.

18. For the line segment from $(-2, 2)$ to $(-1, 0)$, the slope is $\frac{0-2}{-1+2} = -2$, and an equation is $y - 0 = -2(x + 1)$ or, equivalently, $y = -2x - 2$. The circle has equation $x^2 + y^2 = 1$; the top half has equation $y = \sqrt{1 - x^2}$ (we have solved for positive y .) Thus, $f(x) = \begin{cases} -2x - 2 & \text{if } -2 \leq x \leq -1 \\ \sqrt{1 - x^2} & \text{if } -1 < x \leq 1 \end{cases}$

19. $f(x) = \sqrt{x}$, $D = [0, \infty)$; $g(x) = \sin x$, $D = \mathbb{R}$.

$(f \circ g)(x) = f(g(x)) = f(\sin x) = \sqrt{\sin x}$. For $\sqrt{\sin x}$ to be defined, we must have $\sin x \geq 0 \Leftrightarrow x \in [0, \pi], [2\pi, 3\pi], [-2\pi, -\pi], [4\pi, 5\pi], [-4\pi, -3\pi], \dots$, so $D = \{x \mid x \in [2n\pi, \pi + 2n\pi], \text{ where } n \text{ is an integer}\}$.

$(g \circ f)(x) = g(f(x)) = g(\sqrt{x}) = \sin \sqrt{x}$. x must be greater than or equal to 0 for $\sqrt{x}$ to be defined, so $D = [0, \infty)$.

$(f \circ f)(x) = f(f(x)) = f(\sqrt{x}) = \sqrt{\sqrt{x}} = \sqrt[4]{x}$. $D = [0, \infty)$.

$(g \circ g)(x) = g(g(x)) = g(\sin x) = \sin(\sin x)$. $D = \mathbb{R}$.

20. Let $h(x) = x + \sqrt{x}$, $g(x) = \sqrt{x}$, and $f(x) = 1/x$. Then $(f \circ g \circ h)(x) = \frac{1}{\sqrt{x} + \sqrt{x}} = F(x)$.

21. The graphs of $f(x) = \sin^n x$, where n is a positive integer, all have domain $\mathbb{R}$. For odd n , the range is $[-1, 1]$ and for even n , the range is $[0, 1]$. For odd n , the functions are odd and symmetric with respect to the origin. For even n , the functions are even and symmetric with respect to the y -axis. As n becomes large, the graphs become less rounded and more "spiky."

22. (a) Let x denote the number of toaster ovens produced in one week and y the associated cost. Using the points $(1000, 9000)$ and $(1500, 12,000)$, we get an equation of a

$$\text{line: } y - 9000 = \frac{12,000 - 9000}{1500 - 1000} (x - 1000) \Rightarrow$$

$$y = 6(x - 1000) + 9000 \Rightarrow y = 6x + 3000.$$

- (b) The slope of 6 means that each additional toaster oven produced adds \$6 to the weekly production cost.
(c) The y -intercept of 3000 represents the overhead cost—the cost incurred without producing anything.

- 23.

Many models appear to be plausible. Your choice depends on whether you think medical advances will keep increasing life expectancy, or if there is bound to be a natural leveling-off of life expectancy. A linear model, $y = 0.2493x - 423.4818$ gives us an estimate of 77.6 years for the year 2010.

□ PRINCIPLES OF PROBLEM SOLVING

1.

By using the area formula for a triangle, $\frac{1}{2}(\text{base})(\text{height})$, in two ways,

we see that $\frac{1}{2}(4)(y) = \frac{1}{2}(h)(a)$, so $a = \frac{4y}{h}$. Since $4^2 + y^2 = h^2$,

$$y = \sqrt{h^2 - 16}, \text{ and } a = \frac{4\sqrt{h^2 - 16}}{h}.$$

2.

Refer to Example 1, where we obtained $h = \frac{P^2 - 100}{2P}$. The 100 came from 4 times the area of the triangle.

In this case, the area of the triangle is $\frac{1}{2}(h)(12) = 6h$. Thus, $h = \frac{P^2 - 4(6h)}{2P} \Rightarrow 2Ph = P^2 - 24h \Rightarrow$

$$2Ph + 24h = P^2 \Rightarrow h(2P + 24) = P^2 \Rightarrow h = \frac{P^2}{2P + 24}.$$

$$3. |2x - 1| = \begin{cases} 2x - 1 & \text{if } x \geq \frac{1}{2} \\ 1 - 2x & \text{if } x < \frac{1}{2} \end{cases} \quad \text{and} \quad |x + 5| = \begin{cases} x + 5 & \text{if } x \geq -5 \\ -x - 5 & \text{if } x < -5 \end{cases}$$

Therefore, we consider the three cases $x < -5$, $-5 \leq x < \frac{1}{2}$, and $x \geq \frac{1}{2}$.

If $x < -5$, we must have $1 - 2x - (-x - 5) = 3 \Leftrightarrow x = 3$, which is false, since we are considering $x < -5$.

If $-5 \leq x < \frac{1}{2}$, we must have $1 - 2x - (x + 5) = 3 \Leftrightarrow x = -\frac{7}{3}$.

If $x \geq \frac{1}{2}$, we must have $2x - 1 - (x + 5) = 3 \Leftrightarrow x = 9$.

So the two solutions of the equation are $x = -\frac{7}{3}$ and $x = 9$.

$$4. |x - 1| = \begin{cases} x - 1 & \text{if } x \geq 1 \\ 1 - x & \text{if } x < 1 \end{cases} \quad \text{and} \quad |x - 3| = \begin{cases} x - 3 & \text{if } x \geq 3 \\ 3 - x & \text{if } x < 3 \end{cases}$$

Therefore, we consider the three cases $x < 1$, $1 \leq x < 3$, and $x \geq 3$.

If $x < 1$, we must have $1 - x - (3 - x) \geq 5 \Leftrightarrow 0 \geq 7$, which is false.

If $1 \leq x < 3$, we must have $x - 1 - (3 - x) \geq 5 \Leftrightarrow x \geq \frac{9}{2}$, which is false because $x < 3$.

If $x \geq 3$, we must have $x - 1 - (x - 3) \geq 5 \Leftrightarrow 2 \geq 5$, which is false.

All three cases lead to falsehoods, so the inequality has no solution.

5. $f(x) = |x^2 - 4|x| + 3|$. If $x \geq 0$, then $f(x) = |x^2 - 4x + 3| = |(x-1)(x-3)|$.

Case (i): If $0 < x \leq 1$, then $f(x) = x^2 - 4x + 3$.

Case (ii): If $1 < x \leq 3$, then $f(x) = -(x^2 - 4x + 3) = -x^2 + 4x - 3$.

Case (iii): If $x > 3$, then $f(x) = x^2 - 4x + 3$.

This enables us to sketch the graph for $x \geq 0$. Then we use the fact that f is an even function to reflect this part of the graph about the y -axis to obtain the entire graph. Or, we could consider also the cases $x < -3$, $-3 \leq x < -1$, and $-1 \leq x < 0$.

6. $g(x) = |x^2 - 1| - |x^2 - 4|$.

$$|x^2 - 1| = \begin{cases} x^2 - 1 & \text{if } |x| \geq 1 \\ 1 - x^2 & \text{if } |x| < 1 \end{cases} \quad \text{and} \quad |x^2 - 4| = \begin{cases} x^2 - 4 & \text{if } |x| \geq 2 \\ 4 - x^2 & \text{if } |x| < 2 \end{cases}$$

So for $0 \leq |x| < 1$, $g(x) = 1 - x^2 - (4 - x^2) = -3$, for

$1 \leq |x| < 2$, $g(x) = x^2 - 1 - (4 - x^2) = 2x^2 - 5$, and for

$|x| \geq 2$, $g(x) = x^2 - 1 - (x^2 - 4) = 3$.

7. Remember that $|a| = a$ if $a \geq 0$ and that $|a| = -a$ if $a < 0$. Thus,

$$x + |x| = \begin{cases} 2x & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases} \quad \text{and} \quad y + |y| = \begin{cases} 2y & \text{if } y \geq 0 \\ 0 & \text{if } y < 0 \end{cases}$$

We will consider the equation $x + |x| = y + |y|$ in four cases.

(1) $\frac{x \geq 0, y \geq 0}{2x = 2y}$	(2) $\frac{x \geq 0, y < 0}{2x = 0}$	(3) $\frac{x < 0, y \geq 0}{0 = 2y}$	(4) $\frac{x < 0, y < 0}{0 = 0}$
$x = y$	$x = 0$	$0 = y$	

Case 1 gives us the line $y = x$ with nonnegative x and y .

Case 2 gives us the portion of the y -axis with y negative.

Case 3 gives us the portion of the x -axis with x negative.

Case 4 gives us the entire third quadrant.

8. $x^4 - 4x^2 - x^2y^2 + 4y^2 = 0 \Leftrightarrow x^2(x^2 - 4) - y^2(x^2 - 4) = 0 \Leftrightarrow$

$$(x^2 - y^2)(x^2 - 4) = 0 \Leftrightarrow (x + y)(x - y)(x + 2)(x - 2) = 0.$$

So the graph of the equation consists of the graphs of the four lines

$y = -x$, $y = x$, $x = -2$, and $x = 2$.

9. $|x| + |y| \leq 1$. The boundary of the region has equation $|x| + |y| = 1$.

In quadrants I, II, III, and IV, this becomes the lines $x + y = 1$,

$-x + y = 1$, $-x - y = 1$, and $x - y = 1$ respectively.

10. $|x - y| + |x| - |y| \leq 2$

$$\text{Case (i): } x > y > 0 \quad \Leftrightarrow \quad x - y + x - y \leq 2 \quad \Leftrightarrow \quad x - y \leq 1 \quad \Leftrightarrow \quad y \geq x - 1$$

$$\text{Case (ii): } y > x > 0 \quad \Leftrightarrow \quad y - x + x - y \leq 2 \quad \Leftrightarrow \quad 0 \leq 2 \text{ (true)}$$

$$\text{Case (iii): } x > 0 \text{ and } y < 0 \quad \Leftrightarrow \quad x - y + x + y \leq 2 \quad \Leftrightarrow \quad 2x \leq 2 \quad \Leftrightarrow \quad x \leq 1$$

$$\text{Case (iv): } x < 0 \text{ and } y > 0 \quad \Leftrightarrow \quad y - x - x - y \leq 2 \quad \Leftrightarrow \quad -2x \leq 2 \quad \Leftrightarrow \quad x \geq -1$$

$$\text{Case (v): } y < x < 0 \quad \Leftrightarrow \quad x - y - x + y \leq 2 \quad \Leftrightarrow \quad 0 \leq 2 \text{ (true)}$$

$$\text{Case (vi): } x < y < 0 \quad \Leftrightarrow \quad y - x - x + y \leq 2 \quad \Leftrightarrow \quad y - x \leq 1 \quad \Leftrightarrow \quad y \leq x + 1$$

Note: Instead of considering cases (iv), (v), and (vi), we could have noted that the region is unchanged if x and y are replaced by $-x$ and $-y$, so the region is symmetric about the origin. Therefore, we need only draw cases (i), (ii), and (iii), and rotate through 180° about the origin.

11. Let d be the distance traveled on each half of the trip. Let t_1 and t_2 be the times taken for the first and second halves of the trip.

For the first half of the trip we have $t_1 = d/30$ and for the second half we have $t_2 = d/60$. Thus, the average speed

$$\text{for the entire trip is } \frac{\text{total distance}}{\text{total time}} = \frac{2d}{t_1 + t_2} = \frac{2d}{\frac{d}{30} + \frac{d}{60}} = \frac{2d}{\frac{2d}{60}} = \frac{120d}{2d + d} = \frac{120d}{3d} = 40. \text{ The average speed for}$$

the entire trip is 40 mi/h.

12. Let $f = \sin$, $g = x$, and $h = x$. Then the left-hand side of the equation is

$$f \circ (g + h) = \sin(x + x) = \sin 2x = 2 \sin x \cos x; \text{ and the right-hand side is}$$

$$f \circ g + f \circ h = \sin x + \sin x = 2 \sin x. \text{ The two sides are not equal, so the given statement is false.}$$

13. Let S_n be the statement that $7^n - 1$ is divisible by 6.

- S_1 is true because $7^1 - 1 = 6$ is divisible by 6.
- Assume S_k is true, that is, $7^k - 1$ is divisible by 6. In other words, $7^k - 1 = 6m$ for some positive integer m . Then $7^{k+1} - 1 = 7^k \cdot 7 - 1 = (6m + 1) \cdot 7 - 1 = 42m + 6 = 6(7m + 1)$, which is divisible by 6, so S_{k+1} is true.
- Therefore, by mathematical induction, $7^n - 1$ is divisible by 6 for every positive integer n .

14. Let S_n be the statement that $1 + 3 + 5 + \cdots + (2n - 1) = n^2$.

- S_1 is true because $[2(1) - 1] = 1 = 1^2$.
- Assume S_k is true, that is, $1 + 3 + 5 + \cdots + (2k - 1) = k^2$. Then

$$1 + 3 + 5 + \cdots + (2k - 1) + [(2k + 1) - 1] = 1 + 3 + 5 + \cdots + (2k - 1) + (2k + 1) \\ = k^2 + (2k + 1) = (k + 1)^2$$

which shows that S_{k+1} is true.

- Therefore, by mathematical induction, $1 + 3 + 5 + \cdots + (2n - 1) = n^2$ for every positive integer n .

15. $f_0(x) = x^2$ and $f_{n+1}(x) = f_0(f_n(x))$ for $n = 0, 1, 2, \dots$

$$f_1(x) = f_0(f_0(x)) = f_0(x^2) = (x^2)^2 = x^4, f_2(x) = f_0(f_1(x)) = f_0(x^4) = (x^4)^2 = x^8,$$

$$f_3(x) = f_0(f_2(x)) = f_0(x^8) = (x^8)^2 = x^{16}, \dots \text{Thus, a general formula is } f_n(x) = x^{2^{n+1}}.$$

16. (a) $f_0(x) = 1/(2 - x)$ and $f_{n+1} = f_0 \circ f_n$ for $n = 0, 1, 2, \dots$

$$f_1(x) = f_0\left(\frac{1}{2-x}\right) = \frac{1}{2 - \frac{1}{2-x}} = \frac{2-x}{2(2-x)-1} = \frac{2-x}{3-2x},$$

$$f_2(x) = f_0\left(\frac{2-x}{3-2x}\right) = \frac{1}{2 - \frac{2-x}{3-2x}} = \frac{3-2x}{2(3-2x)-(2-x)} = \frac{3-2x}{4-3x},$$

$$f_3(x) = f_0\left(\frac{3-2x}{4-3x}\right) = \frac{1}{2 - \frac{3-2x}{4-3x}} = \frac{4-3x}{2(4-3x)-(3-2x)} = \frac{4-3x}{5-4x}, \dots$$

$$\text{Thus, we conjecture that the general formula is } f_n(x) = \frac{n+1-nx}{n+2-(n+1)x}.$$

To prove this, we use the Principle of Mathematical Induction. We have already verified that f_n is true for

$$n = 1. \text{ Assume that the formula is true for } n = k; \text{ that is, } f_k(x) = \frac{k+1-kx}{k+2-(k+1)x}. \text{ Then}$$

$$f_{k+1}(x) = (f_0 \circ f_k)(x) = f_0(f_k(x)) = f_0\left(\frac{k+1-kx}{k+2-(k+1)x}\right) = \frac{1}{2 - \frac{k+1-kx}{k+2-(k+1)x}} \\ = \frac{k+2-(k+1)x}{2[k+2-(k+1)x] - (k+1-kx)} = \frac{k+2-(k+1)x}{k+3-(k+2)x}$$

This shows that the formula for f_n is true for $n = k + 1$. Therefore, by mathematical induction, the formula is true for all positive integers n .

(b)

From the graph, we can make several observations:

- The values at $x = a$ keep increasing as k increases.
- The vertical asymptote gets closer to $x = 1$ as k increases.
- The horizontal asymptote gets closer to $y = 1$ as k increases.
- The x -intercept for f_{k+1} is the value of the vertical asymptote for f_k .
- The y -intercept for f_k is the value of the horizontal asymptote for f_{k+1} .

2 □ LIMITS AND RATES OF CHANGE

2.1 The Tangent and Velocity Problems

1. (a) Using $P(15, 250)$, we construct the following table:

t	Q	slope = m_{PQ}
5	(5, 694)	$\frac{694-250}{5-15} = -\frac{444}{10} = -44.4$
10	(10, 444)	$\frac{444-250}{10-15} = -\frac{194}{5} = -38.8$
20	(20, 111)	$\frac{111-250}{20-15} = -\frac{139}{5} = -27.8$
25	(25, 28)	$\frac{28-250}{25-15} = -\frac{222}{10} = -22.2$
30	(30, 0)	$\frac{0-250}{30-15} = -\frac{250}{15} = -16.\bar{6}$

- (b) Using the values of t that correspond to the points closest to P ($t = 10$ and $t = 20$), we have

$$\frac{-38.8 + (-27.8)}{2} = -33.3$$

- (c) From the graph, we can estimate the slope of the tangent line at P to be $-\frac{300}{9} = -33.\bar{3}$.

2. (a) Slope = $\frac{2948 - 2530}{42 - 36} = \frac{418}{6} \approx 69.67$ (b) Slope = $\frac{2948 - 2661}{42 - 38} = \frac{287}{4} = 71.75$
(c) Slope = $\frac{2948 - 2806}{42 - 40} = \frac{142}{2} = 71$ (d) Slope = $\frac{3080 - 2948}{44 - 42} = \frac{132}{2} = 66$

From the data, we see that the patient's heart rate is decreasing from 71 to 66 heartbeats/minute after 42 minutes. After being stable for a while, the patient's heart rate is dropping.

3. For the curve $y = x/(1+x)$ and the point $P(1, \frac{1}{2})$:

(a)

	x	Q	m_{PQ}
(i)	0.5	(0.5, 0.333333)	0.333333
(ii)	0.9	(0.9, 0.473684)	0.263158
(iii)	0.99	(0.99, 0.497487)	0.251256
(iv)	0.999	(0.999, 0.499750)	0.250125
(v)	1.5	(1.5, 0.6)	0.2
(vi)	1.1	(1.1, 0.523810)	0.238095
(vii)	1.01	(1.01, 0.502488)	0.248756
(viii)	1.001	(1.001, 0.500250)	0.249875

- (b) The slope appears to be $\frac{1}{4}$.

(c) $y - \frac{1}{2} = \frac{1}{4}(x - 1)$ or
 $y = \frac{1}{4}x + \frac{1}{4}$.

4. For the curve
- $y = \sqrt{x+4}$
- and the point
- $P(5, 3)$
- :

(a)

	x	Q	m_{PQ}
(i)	4.5	(4.5, 2.915476)	0.169048
(ii)	4.9	(4.9, 2.983287)	0.167132
(iii)	4.99	(4.99, 2.998333)	0.166713
(iv)	4.999	(4.999, 2.999833)	0.166671
(v)	5.5	(5.5, 3.082207)	0.164414
(vi)	5.1	(5.1, 3.016621)	0.166206
(vii)	5.01	(5.01, 3.001666)	0.166620
(viii)	5.001	(5.001, 3.000167)	0.166662

(b) The slope appears to be $\frac{1}{6}$.

(c) $y - 3 = \frac{1}{6}(x - 5)$ or

$$y = \frac{1}{6}x + \frac{13}{6}$$

(d)

5. (a)
- $y = y(t) = 40t - 16t^2$
- . At
- $t = 2$
- ,
- $y = 40(2) - 16(2)^2 = 16$
- . The average velocity between times 2 and
- $2 + h$

$$\text{is } v_{\text{ave}} = \frac{y(2+h) - y(2)}{(2+h) - 2} = \frac{[40(2+h) - 16(2+h)^2] - 16}{h} = \frac{-24h - 16h^2}{h} = -24 - 16h, \text{ if } h \neq 0.$$

(i) $[2, 2.5]: h = 0.5, v_{\text{ave}} = -32 \text{ ft/s}$

(ii) $[2, 2.1]: h = 0.1, v_{\text{ave}} = -25.6 \text{ ft/s}$

(iii) $[2, 2.05]: h = 0.05, v_{\text{ave}} = -24.8 \text{ ft/s}$

(iv) $[2, 2.01]: h = 0.01, v_{\text{ave}} = -24.16 \text{ ft/s}$

(b) The instantaneous velocity when $t = 2$ (h approaches 0) is -24 ft/s .

6. The average velocity between
- t
- and
- $t + h$
- seconds is

$$\frac{58(t+h) - 0.83(t+h)^2 - (58t - 0.83t^2)}{h} = \frac{58h - 1.66th - 0.83h^2}{h} = 58 - 1.66t - 0.83h \text{ if } h \neq 0.$$

(a) Here $t = 1$, so the average velocity is $58 - 1.66 - 0.83h = 56.34 - 0.83h$.

(i) $[1, 2]: h = 1, 55.51 \text{ m/s}$

(ii) $[1, 1.5]: h = 0.5, 55.925 \text{ m/s}$

(iii) $[1, 1.1]: h = 0.1, 56.257 \text{ m/s}$

(iv) $[1, 1.01]: h = 0.01, 56.3317 \text{ m/s}$

(v) $[1, 1.001]: h = 0.001, 56.33917 \text{ m/s}$

(b) The instantaneous velocity after 1 second is 56.34 m/s .

7. $s = s(t) = t^3/6$. Average velocity between times 1 and $1 + h$ is

$$v_{\text{ave}} = \frac{s(1+h) - s(1)}{(1+h) - 1} = \frac{(1+h)^3/6 - 1/6}{h} = \frac{h^3 + 3h^2 + 3h}{6h} = \frac{h^2 + 3h + 3}{6} \text{ if } h \neq 0.$$

- (a) (i) $[1, 3]: h = 2, v_{\text{ave}} = \frac{13}{6} \text{ ft/s}$ (ii) $[1, 2]: h = 1, v_{\text{ave}} = \frac{7}{6} \text{ ft/s}$
 (iii) $[1, 1.5]: h = 0.5, v_{\text{ave}} = \frac{19}{24} \text{ ft/s}$ (iv) $[1, 1.1]: h = 0.1, v_{\text{ave}} = \frac{331}{600} \text{ ft/s}$

- (b) As h approaches 0, the velocity approaches $\frac{3}{6} = \frac{1}{2} \text{ ft/s}$.

8. Average velocity between times $t = 2$ and $t = 2 + h$ is given by $\frac{s(2+h) - s(2)}{h}$.

(a) (i) $h = 3 \Rightarrow v_{\text{av}} = \frac{s(5) - s(2)}{5 - 2} = \frac{178 - 32}{3} = \frac{146}{3} \approx 48.7 \text{ ft/s}$

(ii) $h = 2 \Rightarrow v_{\text{av}} = \frac{s(4) - s(2)}{4 - 2} = \frac{119 - 32}{2} = \frac{87}{2} = 43.5 \text{ ft/s}$

(iii) $h = 1 \Rightarrow v_{\text{av}} = \frac{s(3) - s(2)}{3 - 2} = \frac{70 - 32}{1} = 38 \text{ ft/s}$

- (b) Using the points $(0.8, 0)$ and $(5, 118)$ from the approximate tangent line, the instantaneous velocity at $t = 2$ is about $\frac{118 - 0}{5 - 0.8} \approx 28 \text{ ft/s}$.

9. For the curve $y = \sin(10\pi/x)$ and the point $P(1, 0)$:

(a)

x	Q	m_{PQ}
2	(2, 0)	0
1.5	(1.5, 0.8660)	1.7321
1.4	(1.4, -0.4339)	-1.0847
1.3	(1.3, -0.8230)	-2.7433
1.2	(1.2, 0.8660)	4.3301
1.1	(1.1, -0.2817)	-2.8173

x	Q	m_{PQ}
0.5	(0.5, 0)	0
0.6	(0.6, 0.8660)	-2.1651
0.7	(0.7, 0.7818)	-2.6061
0.8	(0.8, 1)	-5
0.9	(0.9, -0.3420)	3.4202

As x approaches 1, the slopes do not appear to be approaching any particular value.

(b)

We see that problems with estimation are caused by the frequent oscillations of the graph. The tangent is so steep at P that we need to take x -values much closer to 1 in order to get accurate estimates of its slope.

- (c) If we choose $x = 1.001$, then the point Q is $(1.001, -0.0314)$ and $m_{PQ} \approx -31.3794$. If $x = 0.999$, then Q is $(0.999, 0.0314)$ and $m_{PQ} = -31.4422$. The average of these slopes is -31.4108 . So we estimate that the slope of the tangent line at P is about -31.4 .

2.2 The Limit of a Function

- As x approaches 2, $f(x)$ approaches 5. [Or, the values of $f(x)$ can be made as close to 5 as we like by taking x sufficiently close to 2 (but $x \neq 2$).] Yes, the graph could have a hole at $(2, 5)$ and be defined such that $f(2) = 3$.
- As x approaches 1 from the left, $f(x)$ approaches 3; and as x approaches 1 from the right, $f(x)$ approaches 7. No, the limit does not exist because the left- and right-hand limits are different.
- $\lim_{x \rightarrow -3} f(x) = \infty$ means that the values of $f(x)$ can be made arbitrarily large (as large as we please) by taking x sufficiently close to -3 (but not equal to -3).
 - $\lim_{x \rightarrow 4^+} f(x) = -\infty$ means that the values of $f(x)$ can be made arbitrarily large negative by taking x sufficiently close to 4 through values larger than 4.
- $\lim_{x \rightarrow 0} f(x) = 3$
 - $\lim_{x \rightarrow 3^-} f(x) = 4$
 - $\lim_{x \rightarrow 3^+} f(x) = 2$
 - $\lim_{x \rightarrow 3} f(x)$ does not exist because the limits in part (b) and part (c) are not equal.
 - $f(3) = 3$
- $f(x)$ approaches 2 as x approaches 1 from the left, so $\lim_{x \rightarrow 1^-} f(x) = 2$.
 - $f(x)$ approaches 3 as x approaches 1 from the right, so $\lim_{x \rightarrow 1^+} f(x) = 3$.
 - $\lim_{x \rightarrow 1} f(x)$ does not exist because the limits in part (a) and part (b) are not equal.
 - $f(x)$ approaches 4 as x approaches 5 from the left and from the right, so $\lim_{x \rightarrow 5} f(x) = 4$.
 - $f(5)$ is not defined, so it doesn't exist.
- $\lim_{x \rightarrow -2^-} g(x) = -1$
 - $\lim_{x \rightarrow -2^+} g(x) = 1$
 - $\lim_{x \rightarrow -2} g(x)$ doesn't exist
 - $g(-2) = 1$
 - $\lim_{x \rightarrow 2^-} g(x) = 1$
 - $\lim_{x \rightarrow 2^+} g(x) = 2$
 - $\lim_{x \rightarrow 2} g(x)$ doesn't exist
 - $\lim_{x \rightarrow 2} g(x)$ doesn't exist
 - $\lim_{x \rightarrow 4^+} g(x)$ doesn't exist
 - $\lim_{x \rightarrow 4^-} g(x) = 2$
 - $g(0)$ doesn't exist
 - $\lim_{x \rightarrow 0} g(x) = 0$

7. (a) $\lim_{t \rightarrow 0^-} g(t) = -1$

(b) $\lim_{t \rightarrow 0^+} g(t) = -2$

 (c) $\lim_{t \rightarrow 0} g(t)$ does not exist because the limits in part (a) and part (b) are not equal.

(d) $\lim_{t \rightarrow 2^-} g(t) = 2$

(e) $\lim_{t \rightarrow 2^+} g(t) = 0$

 (f) $\lim_{t \rightarrow 2} g(t)$ does not exist because the limits in part (d) and part (e) are not equal.

(g) $g(2) = 1$

(h) $\lim_{t \rightarrow 4} g(t) = 3$

8. (a) $\lim_{x \rightarrow 2} R(x) = -\infty$

(b) $\lim_{x \rightarrow 5} R(x) = \infty$

(c) $\lim_{x \rightarrow -3^-} R(x) = -\infty$

(d) $\lim_{x \rightarrow -3^+} R(x) = \infty$

 (e) The equations of the vertical asymptotes are $x = -3$, $x = 2$, and $x = 5$.

9. (a) $\lim_{x \rightarrow -7} f(x) = -\infty$

(b) $\lim_{x \rightarrow -3} f(x) = \infty$

(c) $\lim_{x \rightarrow 0} f(x) = \infty$

(d) $\lim_{x \rightarrow 6^-} f(x) = -\infty$

(e) $\lim_{x \rightarrow 6^+} f(x) = \infty$

 (f) The equations of the vertical asymptotes are $x = -7$, $x = -3$, $x = 0$, and $x = 6$.

 10. $\lim_{t \rightarrow 12^-} f(t) = 150$ mg and $\lim_{t \rightarrow 12^+} f(t) = 300$ mg. These limits show that there is an abrupt change in the amount of drug in the patient's bloodstream at $t = 12$ h. The left-hand limit represents the amount of the drug just before the fourth injection. The right-hand limit represents the amount of the drug just after the fourth injection.

11.

(a) $\lim_{x \rightarrow 0^-} f(x) = 1$

(b) $\lim_{x \rightarrow 0^+} f(x) = 0$

 (c) $\lim_{x \rightarrow 0} f(x)$ does not exist because the limits in part (a) and part (b) are not equal.

 12. $\lim_{x \rightarrow a} f(x)$ exists for all a except $a = \pm 1$.

13. $\lim_{x \rightarrow 3^+} f(x) = 4$, $\lim_{x \rightarrow 3^-} f(x) = 2$,
 $\lim_{x \rightarrow -2} f(x) = 2$, $f(3) = 3$, $f(-2) = 1$

14. $\lim_{x \rightarrow 0^-} f(x) = 1$, $\lim_{x \rightarrow 0^+} f(x) = -1$,
 $\lim_{x \rightarrow 2^-} f(x) = 0$, $\lim_{x \rightarrow 2^+} f(x) = 1$, $f(2) = 1$,
 $f(0)$ is undefined

15. For $f(x) = \frac{x^2 - 2x}{x^2 - x - 2}$:

x	$f(x)$	x	$f(x)$
2.5	0.714286	1.9	0.655172
2.1	0.677419	1.95	0.661017
2.05	0.672131	1.99	0.665552
2.01	0.667774	1.995	0.666110
2.005	0.667221	1.999	0.666556
2.001	0.666778		

It appears that $\lim_{x \rightarrow 2} \frac{x^2 - 2x}{x^2 - x - 2} = 0.6 = \frac{2}{3}$.

16. For $f(x) = \frac{x^2 - 2x}{x^2 - x - 2}$:

x	$f(x)$	x	$f(x)$
0	0	-2	2
-0.5	-1	-1.5	3
-0.9	-9	-1.1	11
-0.95	-19	-1.01	101
-0.99	-99	-1.001	1001
-0.999	-999		

It appears that $\lim_{x \rightarrow -1} \frac{x^2 - 2x}{x^2 - x - 2}$ does not exist

since $f(x) \rightarrow -\infty$ as $x \rightarrow -1^-$ and $f(x) \rightarrow \infty$ as $x \rightarrow -1^+$.

17. For $f(x) = \frac{\sin x}{x + \tan x}$:

x	$f(x)$
± 1	0.329033
± 0.5	0.458209
± 0.2	0.493331
± 0.1	0.498333
± 0.05	0.499583
± 0.01	0.499983

It appears that $\lim_{x \rightarrow 0} \frac{\sin x}{x + \tan x} = 0.5 = \frac{1}{2}$.

18. For $f(x) = \frac{\sqrt{x} - 4}{x - 16}$:

x	$f(x)$	x	$f(x)$
17	0.123106	15	0.127017
16.5	0.124038	15.5	0.125992
16.1	0.124805	15.9	0.125196
16.05	0.124902	15.95	0.125098
16.01	0.124980	15.99	0.125020

It appears that $\lim_{x \rightarrow 16} \frac{\sqrt{x} - 4}{x - 16} = 0.125 = \frac{1}{8}$.

19. For $f(x) = \frac{\sqrt{x+4} - 2}{x}$:

x	$f(x)$
1	0.236068
0.5	0.242641
0.1	0.248457
0.05	0.249224
0.01	0.249844

x	$f(x)$
-1	0.267949
-0.5	0.258343
-0.1	0.251582
-0.05	0.250786
-0.01	0.250156

It appears that $\lim_{x \rightarrow 0} \frac{\sqrt{x+4} - 2}{x} = 0.25 = \frac{1}{4}$.

20. For $f(x) = \frac{\tan 3x}{\tan 5x}$:

x	$f(x)$
± 0.2	0.439279
± 0.1	0.566236
± 0.05	0.591893
± 0.01	0.599680
± 0.001	0.599997

It appears that $\lim_{x \rightarrow 0} \frac{\tan 3x}{\tan 5x} = 0.6 = \frac{3}{5}$.

21. For $f(x) = \frac{x^6 - 1}{x^{10} - 1}$:

x	$f(x)$
0.5	0.985337
0.9	0.719397
0.95	0.660186
0.99	0.612018
0.999	0.601200

x	$f(x)$
1.5	0.183369
1.1	0.484119
1.05	0.540783
1.01	0.588022
1.001	0.598800

It appears that $\lim_{x \rightarrow 1} \frac{x^6 - 1}{x^{10} - 1} = 0.6 = \frac{3}{5}$.

22. For $f(x) = \frac{9^x - 5^x}{x}$:

x	$f(x)$
0.5	1.527864
0.1	0.711120
0.05	0.646496
0.01	0.599082
0.001	0.588906

x	$f(x)$
-0.5	0.227761
-0.1	0.485984
-0.05	0.534447
-0.01	0.576706
-0.001	0.586669

It appears that $\lim_{x \rightarrow 0} \frac{9^x - 5^x}{x} = 0.59$. Later we will be able to show that the exact value is $\ln(9/5)$.

23. $\lim_{x \rightarrow 5^+} \frac{6}{x-5} = \infty$ since $(x-5) \rightarrow 0$ as $x \rightarrow 5^+$ and $\frac{6}{x-5} > 0$ for $x > 5$.

24. $\lim_{x \rightarrow 5^-} \frac{6}{x-5} = -\infty$ since $(x-5) \rightarrow 0$ as $x \rightarrow 5^-$ and $\frac{6}{x-5} < 0$ for $x < 5$.

25. $\lim_{x \rightarrow 1} \frac{2-x}{(x-1)^2} = \infty$ since the numerator is positive and the denominator approaches 0 through positive values as $x \rightarrow 1$.

26. $\lim_{x \rightarrow 0} \frac{x-1}{x^2(x+2)} = -\infty$ since $x^2 \rightarrow 0$ as $x \rightarrow 0$ and $\frac{x-1}{x^2(x+2)} < 0$ for $0 < x < 1$ and for $-2 < x < 0$.

27. $\lim_{x \rightarrow -2^+} \frac{x-1}{x^2(x+2)} = -\infty$ since $(x+2) \rightarrow 0$ as $x \rightarrow -2^+$ and $\frac{x-1}{x^2(x+2)} < 0$ for $-2 < x < 0$.

28. $\lim_{x \rightarrow \pi^-} \csc x = \lim_{x \rightarrow \pi^-} (1/\sin x) = \infty$ since $\sin x \rightarrow 0$ as $x \rightarrow \pi^-$ and $\sin x > 0$ for $0 < x < \pi$.

29. $\lim_{x \rightarrow (-\pi/2)^-} \sec x = \lim_{x \rightarrow (-\pi/2)^-} (1/\cos x) = -\infty$ since $\cos x \rightarrow 0$ as $x \rightarrow (-\pi/2)^-$ and $\cos x < 0$ for $-\pi < x < -\pi/2$.

30. $\lim_{x \rightarrow 1^+} \frac{x+1}{x \sin \pi x} = -\infty$ since $\frac{x+1}{x} \rightarrow 2$ as $x \rightarrow 1^+$ and $\sin \pi x \rightarrow 0$ through negative values as $x \rightarrow 1^+$.

31. (a) $f(x) = 1/(x^3 - 1)$

x	$f(x)$
0.5	-1.14
0.9	-3.69
0.99	-33.7
0.999	-333.7
0.9999	-3333.7
0.99999	-33,333.7

x	$f(x)$
1.5	0.42
1.1	3.02
1.01	33.0
1.001	333.0
1.0001	3333.0
1.00001	33,333.3

From these calculations, it seems that $\lim_{x \rightarrow 1^-} f(x) = -\infty$ and $\lim_{x \rightarrow 1^+} f(x) = \infty$.

(b) If x is slightly smaller than 1, then $x^3 - 1$ will be a negative number close to 0, and the reciprocal of $x^3 - 1$, that is, $f(x)$, will be a negative number with large absolute value. So $\lim_{x \rightarrow 1^-} f(x) = -\infty$.

If x is slightly larger than 1, then $x^3 - 1$ will be a small positive number, and its reciprocal, $f(x)$, will be a large positive number. So $\lim_{x \rightarrow 1^+} f(x) = \infty$.

(c) It appears from the graph of f that $\lim_{x \rightarrow 1^-} f(x) = -\infty$ and

$$\lim_{x \rightarrow 1^+} f(x) = \infty.$$

32. (a) $y = \frac{x}{x^2 - x - 2} = \frac{x}{(x-2)(x+1)}$. Therefore, as $x \rightarrow -1^+$ or

$x \rightarrow 2^+$, the denominator approaches 0, and $y > 0$ for $x < -1$ and for $x > 2$, so $\lim_{x \rightarrow -1^+} y = \lim_{x \rightarrow 2^+} y = \infty$. Also, as $x \rightarrow -1^-$ or

$x \rightarrow 2^-$, the denominator approaches 0 and $y < 0$ for $-1 < x < 2$, so $\lim_{x \rightarrow -1^-} y = \lim_{x \rightarrow 2^-} y = -\infty$.

33. (a) Let
- $h(x) = (1+x)^{1/x}$
- .

x	$h(x)$
-0.001	2.71964
-0.0001	2.71842
-0.00001	2.71830
-0.000001	2.71828
0.000001	2.71828
0.00001	2.71827
0.0001	2.71815
0.001	2.71692

It appears that $\lim_{x \rightarrow 0} (1+x)^{1/x} \approx 2.71828$, which is approximately e .

In Section 7.4 we will see that the value of the limit is exactly e .

34. For the curve
- $y = 2^x$
- and the points
- $P(0, 1)$
- and
- $Q(x, 2^x)$
- :

x	Q	m_{PQ}
0.1	(0.1, 1.0717735)	0.71773
0.01	(0.01, 1.0069556)	0.69556
0.001	(0.001, 1.0006934)	0.69339
0.0001	(0.0001, 1.0000693)	0.69317

The slope appears to be about 0.693.

35. For
- $f(x) = x^2 - (2^x/1000)$
- :

(a)

x	$f(x)$
1	0.998000
0.8	0.638259
0.6	0.358484
0.4	0.158680
0.2	0.038851
0.1	0.008928
0.05	0.001465

It appears that $\lim_{x \rightarrow 0} f(x) = 0$.

(b)

x	$f(x)$
0.04	0.000572
0.02	-0.000614
0.01	-0.000907
0.005	-0.000978
0.003	-0.000993
0.001	-0.001000

It appears that $\lim_{x \rightarrow 0} f(x) = -0.001$.

36. $h(x) = \frac{\tan x - x}{x^3}$

(a)

x	$h(x)$
1.0	0.55740773
0.5	0.37041992
0.1	0.33467209
0.05	0.33366700
0.01	0.33334667
0.005	0.33333667

(c)

x	$h(x)$
0.001	0.33333350
0.0005	0.33333344
0.0001	0.33333000
0.00005	0.33333600
0.00001	0.33300000
0.000001	0.00000000

(b) It seems that $\lim_{x \rightarrow 0} h(x) = \frac{1}{3}$.

Here the values will vary from one calculator to another.

Every calculator will eventually give *false values*.

(d) As in part (c), when we take a small enough viewing rectangle we get incorrect output.

37. No matter how many times we zoom in toward the origin, the graphs of $f(x) = \sin(\pi/x)$ appear to consist of almost-vertical lines. This indicates more and more frequent oscillations as $x \rightarrow 0$.

38. $\lim_{v \rightarrow c^-} m = \lim_{v \rightarrow c^-} \frac{m_0}{\sqrt{1 - v^2/c^2}}$. As $v \rightarrow c^-$, $\sqrt{1 - v^2/c^2} \rightarrow 0^+$, and $m \rightarrow \infty$.

There appear to be vertical asymptotes of the curve $y = \tan(2 \sin x)$ at $x \approx \pm 0.90$ and $x \approx \pm 2.24$. To find the exact equations of these asymptotes, we note that the graph of the tangent function has vertical asymptotes at $x = \frac{\pi}{2} + \pi n$. Thus, we must have $2 \sin x = \frac{\pi}{2} + \pi n$, or equivalently, $\sin x = \frac{\pi}{4} + \frac{\pi}{2} n$. Since $-1 \leq \sin x \leq 1$, we must have $\sin x = \pm \frac{\pi}{4}$ and so $x = \pm \sin^{-1} \frac{\pi}{4}$ (corresponding to $x \approx \pm 0.90$).

Just as 150° is the reference angle for 30° , $\pi - \sin^{-1} \frac{\pi}{4}$ is the reference angle for $\sin^{-1} \frac{\pi}{4}$. So $x = \pm(\pi - \sin^{-1} \frac{\pi}{4})$ are also equations of the vertical asymptotes (corresponding to $x \approx \pm 2.24$).

40. (a) Let $y = (x^3 - 1)/(\sqrt{x} - 1)$.

x	y
0.99	5.92531
0.999	5.99250
0.9999	5.99925
1.01	6.07531
1.001	6.00750
1.0001	6.00075

From the table and the graph, we guess that the limit of y as x approaches 1 is 6.

(b) We need to have $5.5 < \frac{x^3 - 1}{\sqrt{x} - 1} < 6.5$. From the graph we obtain the approximate points of intersection

$P(0.9313853, 5.5)$ and $Q(1.0649004, 6.5)$. Now $1 - 0.9313853 \approx 0.0686$ and $1.0649004 - 1 \approx 0.0649$, so by requiring that x be within 0.0649 of 1, we ensure that y is within 0.5 of 6.

2.3 Calculating Limits Using the Limit Laws

1. (a) $\lim_{x \rightarrow a} [f(x) + h(x)] = \lim_{x \rightarrow a} f(x) + \lim_{x \rightarrow a} h(x)$
 $= -3 + 8 = 5$

(b) $\lim_{x \rightarrow a} [f(x)]^2 = \left[\lim_{x \rightarrow a} f(x) \right]^2 = (-3)^2 = 9$

(c) $\lim_{x \rightarrow a} \sqrt[3]{h(x)} = \sqrt[3]{\lim_{x \rightarrow a} h(x)} = \sqrt[3]{8} = 2$

(d) $\lim_{x \rightarrow a} \frac{1}{f(x)} = \frac{1}{\lim_{x \rightarrow a} f(x)} = \frac{1}{-3} = -\frac{1}{3}$

(e) $\lim_{x \rightarrow a} \frac{f(x)}{h(x)} = \frac{\lim_{x \rightarrow a} f(x)}{\lim_{x \rightarrow a} h(x)} = \frac{-3}{8} = -\frac{3}{8}$

(f) $\lim_{x \rightarrow a} \frac{g(x)}{f(x)} = \frac{\lim_{x \rightarrow a} g(x)}{\lim_{x \rightarrow a} f(x)} = \frac{0}{-3} = 0$

(g) The limit does not exist, since $\lim_{x \rightarrow a} g(x) = 0$ but $\lim_{x \rightarrow a} f(x) \neq 0$.

(h) $\lim_{x \rightarrow a} \frac{2f(x)}{h(x) - f(x)} = \frac{2 \lim_{x \rightarrow a} f(x)}{\lim_{x \rightarrow a} h(x) - \lim_{x \rightarrow a} f(x)} = \frac{2(-3)}{8 - (-3)} = -\frac{6}{11}$

$$2. (a) \lim_{x \rightarrow 2} [f(x) + g(x)] = \lim_{x \rightarrow 2} f(x) + \lim_{x \rightarrow 2} g(x) = 2 + 0 = 2$$

(b) $\lim_{x \rightarrow 1} g(x)$ does not exist since its left- and right-hand limits are not equal, so the given limit does not exist.

$$(c) \lim_{x \rightarrow 0} [f(x)g(x)] = \lim_{x \rightarrow 0} f(x) \cdot \lim_{x \rightarrow 0} g(x) = 0 \cdot 1.3 = 0$$

(d) Since $\lim_{x \rightarrow -1} g(x) = 0$ and g is in the denominator, but $\lim_{x \rightarrow -1} f(x) = -1 \neq 0$, the given limit does not exist.

$$(e) \lim_{x \rightarrow 2} x^3 f(x) = \left[\lim_{x \rightarrow 2} x^3 \right] \left[\lim_{x \rightarrow 2} f(x) \right] = 2^3 \cdot 2 = 16$$

$$(f) \lim_{x \rightarrow 1} \sqrt{3 + f(x)} = \sqrt{3 + \lim_{x \rightarrow 1} f(x)} = \sqrt{3 + 1} = 2$$

$$\begin{aligned} 3. \lim_{x \rightarrow -2} (3x^4 + 2x^2 - x + 1) &= \lim_{x \rightarrow -2} 3x^4 + \lim_{x \rightarrow -2} 2x^2 - \lim_{x \rightarrow -2} x + \lim_{x \rightarrow -2} 1 && \text{[Limit Laws 1 and 2]} \\ &= 3 \lim_{x \rightarrow -2} x^4 + 2 \lim_{x \rightarrow -2} x^2 - \lim_{x \rightarrow -2} x + \lim_{x \rightarrow -2} 1 && [3] \\ &= 3(-2)^4 + 2(-2)^2 - (-2) + (1) && [9, 8, \text{ and } 7] \\ &= 48 + 8 + 2 + 1 = 59 \end{aligned}$$

$$\begin{aligned} 4. \lim_{x \rightarrow 2} \frac{2x^2 + 1}{x^2 + 6x - 4} &= \frac{\lim_{x \rightarrow 2} (2x^2 + 1)}{\lim_{x \rightarrow 2} (x^2 + 6x - 4)} && \text{[Limit Law 5]} \\ &= \frac{2 \lim_{x \rightarrow 2} x^2 + \lim_{x \rightarrow 2} 1}{\lim_{x \rightarrow 2} x^2 + 6 \lim_{x \rightarrow 2} x - \lim_{x \rightarrow 2} 4} && [2, 1, \text{ and } 3] \\ &= \frac{2(2)^2 + 1}{(2)^2 + 6(2) - 4} = \frac{9}{12} = \frac{3}{4} && [9, 7, \text{ and } 8] \end{aligned}$$

$$\begin{aligned} 5. \lim_{x \rightarrow 3} (x^2 - 4)(x^3 + 5x - 1) &= \lim_{x \rightarrow 3} (x^2 - 4) \cdot \lim_{x \rightarrow 3} (x^3 + 5x - 1) && \text{[Limit Law 4]} \\ &= \left(\lim_{x \rightarrow 3} x^2 - \lim_{x \rightarrow 3} 4 \right) \cdot \left(\lim_{x \rightarrow 3} x^3 + 5 \lim_{x \rightarrow 3} x - \lim_{x \rightarrow 3} 1 \right) && [2, 1, \text{ and } 3] \\ &= (3^2 - 4) \cdot (3^3 + 5 \cdot 3 - 1) && [7, 8, \text{ and } 9] \\ &= 5 \cdot 41 = 205 \end{aligned}$$

$$\begin{aligned} 6. \lim_{t \rightarrow -1} (t^2 + 1)^3 (t + 3)^5 &= \lim_{t \rightarrow -1} (t^2 + 1)^3 \cdot \lim_{t \rightarrow -1} (t + 3)^5 && \text{[Limit Law 4]} \\ &= \left[\lim_{t \rightarrow -1} (t^2 + 1) \right]^3 \cdot \left[\lim_{t \rightarrow -1} (t + 3) \right]^5 && [6] \\ &= \left[\lim_{t \rightarrow -1} t^2 + \lim_{t \rightarrow -1} 1 \right]^3 \cdot \left[\lim_{t \rightarrow -1} t + \lim_{t \rightarrow -1} 3 \right]^5 && [1] \\ &= [(-1)^2 + 1]^3 \cdot [-1 + 3]^5 = 8 \cdot 32 = 256 && [9, 7, \text{ and } 8] \end{aligned}$$

$$7. \lim_{x \rightarrow 1} \left(\frac{1 + 3x}{1 + 4x^2 + 3x^4} \right)^3 = \left(\lim_{x \rightarrow 1} \frac{1 + 3x}{1 + 4x^2 + 3x^4} \right)^3 \quad [6]$$

$$= \left[\frac{\lim_{x \rightarrow 1} (1 + 3x)}{\lim_{x \rightarrow 1} (1 + 4x^2 + 3x^4)} \right]^3 \quad [5]$$

$$= \left[\frac{\lim_{x \rightarrow 1} 1 + 3 \lim_{x \rightarrow 1} x}{\lim_{x \rightarrow 1} 1 + 4 \lim_{x \rightarrow 1} x^2 + 3 \lim_{x \rightarrow 1} x^4} \right]^3 \quad [2, 1, \text{ and } 3]$$

$$= \left[\frac{1 + 3(1)}{1 + 4(1)^2 + 3(1)^4} \right]^3 = \left[\frac{4}{8} \right]^3 = \left(\frac{1}{2} \right)^3 = \frac{1}{8} \quad [7, 8, \text{ and } 9]$$

$$8. \lim_{u \rightarrow -2} \sqrt{u^4 + 3u + 6} = \sqrt{\lim_{u \rightarrow -2} (u^4 + 3u + 6)} \quad [11]$$

$$= \sqrt{\lim_{u \rightarrow -2} u^4 + 3 \lim_{u \rightarrow -2} u + \lim_{u \rightarrow -2} 6} \quad [1, 2, \text{ and } 3]$$

$$= \sqrt{(-2)^4 + 3(-2) + 6} \quad [9, 8, \text{ and } 7]$$

$$= \sqrt{16 - 6 + 6} = \sqrt{16} = 4$$

$$9. \lim_{x \rightarrow 4^-} \sqrt{16 - x^2} = \sqrt{\lim_{x \rightarrow 4^-} (16 - x^2)} \quad [11]$$

$$= \sqrt{\lim_{x \rightarrow 4^-} 16 - \lim_{x \rightarrow 4^-} x^2} \quad [2]$$

$$= \sqrt{16 - (4)^2} = 0 \quad [7 \text{ and } 9]$$

10. (a) The left-hand side of the equation is not defined for $x = 2$, but the right-hand side is.

(b) Since the equation holds for all $x \neq 2$, it follows that both sides of the equation approach the same limit as $x \rightarrow 2$, just as in Example 3. Remember that in finding $\lim_{x \rightarrow a} f(x)$, we never consider $x = a$.

$$11. \lim_{x \rightarrow 2} \frac{x^2 + x - 6}{x - 2} = \lim_{x \rightarrow 2} \frac{(x + 3)(x - 2)}{x - 2} = \lim_{x \rightarrow 2} (x + 3) = 2 + 3 = 5$$

$$12. \lim_{x \rightarrow -4} \frac{x^2 + 5x + 4}{x^2 + 3x - 4} = \lim_{x \rightarrow -4} \frac{(x + 4)(x + 1)}{(x + 4)(x - 1)} = \lim_{x \rightarrow -4} \frac{x + 1}{x - 1} = \frac{-4 + 1}{-4 - 1} = \frac{-3}{-5} = \frac{3}{5}$$

$$13. \lim_{x \rightarrow 2} \frac{x^2 - x + 6}{x - 2} \text{ does not exist since } x - 2 \rightarrow 0 \text{ but } x^2 - x + 6 \rightarrow 8 \text{ as } x \rightarrow 2.$$

$$14. \lim_{x \rightarrow 4} \frac{x^2 - 4x}{x^2 - 3x - 4} = \lim_{x \rightarrow 4} \frac{x(x - 4)}{(x - 4)(x + 1)} = \lim_{x \rightarrow 4} \frac{x}{x + 1} = \frac{4}{4 + 1} = \frac{4}{5}$$

$$15. \lim_{t \rightarrow -3} \frac{t^2 - 9}{2t^2 + 7t + 3} = \lim_{t \rightarrow -3} \frac{(t + 3)(t - 3)}{(2t + 1)(t + 3)} = \lim_{t \rightarrow -3} \frac{t - 3}{2t + 1} = \frac{-3 - 3}{2(-3) + 1} = \frac{-6}{-5} = \frac{6}{5}$$

$$16. \lim_{x \rightarrow -1} \frac{x^2 - 4x}{x^2 - 3x - 4} \text{ does not exist since } x^2 - 3x - 4 \rightarrow 0 \text{ but } x^2 - 4x \rightarrow 5 \text{ as } x \rightarrow -1.$$

$$17. \lim_{h \rightarrow 0} \frac{(4 + h)^2 - 16}{h} = \lim_{h \rightarrow 0} \frac{(16 + 8h + h^2) - 16}{h} = \lim_{h \rightarrow 0} \frac{8h + h^2}{h} = \lim_{h \rightarrow 0} \frac{h(8 + h)}{h} = \lim_{h \rightarrow 0} (8 + h) = 8 + 0 = 8$$

$$18. \lim_{x \rightarrow 1} \frac{x^3 - 1}{x^2 - 1} = \lim_{x \rightarrow 1} \frac{(x - 1)(x^2 + x + 1)}{(x - 1)(x + 1)} = \lim_{x \rightarrow 1} \frac{x^2 + x + 1}{x + 1} = \frac{1^2 + 1 + 1}{1 + 1} = \frac{3}{2}$$

$$\begin{aligned}
 19. \lim_{h \rightarrow 0} \frac{(1+h)^4 - 1}{h} &= \lim_{h \rightarrow 0} \frac{(1 + 4h + 6h^2 + 4h^3 + h^4) - 1}{h} = \lim_{h \rightarrow 0} \frac{4h + 6h^2 + 4h^3 + h^4}{h} \\
 &= \lim_{h \rightarrow 0} \frac{h(4 + 6h + 4h^2 + h^3)}{h} = \lim_{h \rightarrow 0} (4 + 6h + 4h^2 + h^3) = 4 + 0 + 0 + 0 = 4
 \end{aligned}$$

$$\begin{aligned}
 20. \lim_{h \rightarrow 0} \frac{(2+h)^3 - 8}{h} &= \lim_{h \rightarrow 0} \frac{(8 + 12h + 6h^2 + h^3) - 8}{h} = \lim_{h \rightarrow 0} \frac{12h + 6h^2 + h^3}{h} \\
 &= \lim_{h \rightarrow 0} (12 + 6h + h^2) = 12 + 0 + 0 = 12
 \end{aligned}$$

$$21. \lim_{t \rightarrow 9} \frac{9-t}{3-\sqrt{t}} = \lim_{t \rightarrow 9} \frac{(3+\sqrt{t})(3-\sqrt{t})}{3-\sqrt{t}} = \lim_{t \rightarrow 9} (3+\sqrt{t}) = 3 + \sqrt{9} = 6$$

$$\begin{aligned}
 22. \lim_{h \rightarrow 0} \frac{\sqrt{1+h} - 1}{h} &= \lim_{h \rightarrow 0} \frac{\sqrt{1+h} - 1}{h} \cdot \frac{\sqrt{1+h} + 1}{\sqrt{1+h} + 1} = \lim_{h \rightarrow 0} \frac{(1+h) - 1}{h(\sqrt{1+h} + 1)} = \lim_{h \rightarrow 0} \frac{h}{h(\sqrt{1+h} + 1)} \\
 &= \lim_{h \rightarrow 0} \frac{1}{\sqrt{1+h} + 1} = \frac{1}{\sqrt{1+0} + 1} = \frac{1}{2}
 \end{aligned}$$

$$\begin{aligned}
 23. \lim_{x \rightarrow 7} \frac{\sqrt{x+2} - 3}{x-7} &= \lim_{x \rightarrow 7} \frac{\sqrt{x+2} - 3}{x-7} \cdot \frac{\sqrt{x+2} + 3}{\sqrt{x+2} + 3} = \lim_{x \rightarrow 7} \frac{(x+2) - 9}{(x-7)(\sqrt{x+2} + 3)} \\
 &= \lim_{x \rightarrow 7} \frac{x-7}{(x-7)(\sqrt{x+2} + 3)} = \lim_{x \rightarrow 7} \frac{1}{\sqrt{x+2} + 3} = \frac{1}{\sqrt{9} + 3} = \frac{1}{6}
 \end{aligned}$$

$$\begin{aligned}
 24. \lim_{x \rightarrow 2} \frac{x^4 - 16}{x-2} &= \lim_{x \rightarrow 2} \frac{(x+2)(x-2)(x^2+4)}{x-2} = \lim_{x \rightarrow 2} (x+2)(x^2+4) = \lim_{x \rightarrow 2} (x+2) \lim_{x \rightarrow 2} (x^2+4) \\
 &= (2+2)(2^2+4) = 32
 \end{aligned}$$

$$25. \lim_{x \rightarrow -4} \frac{\frac{1}{4} + \frac{1}{x}}{4+x} = \lim_{x \rightarrow -4} \frac{\frac{x+4}{4x}}{4+x} = \lim_{x \rightarrow -4} \frac{x+4}{4x(4+x)} = \lim_{x \rightarrow -4} \frac{1}{4x} = \frac{1}{4(-4)} = -\frac{1}{16}$$

$$26. \lim_{t \rightarrow 0} \left(\frac{1}{t} - \frac{1}{t^2+t} \right) = \lim_{t \rightarrow 0} \frac{(t^2+t) - t}{t(t^2+t)} = \lim_{t \rightarrow 0} \frac{t^2}{t \cdot t(t+1)} = \lim_{t \rightarrow 0} \frac{1}{t+1} = \frac{1}{0+1} = 1$$

$$\begin{aligned}
 27. \lim_{x \rightarrow 9} \frac{x^2 - 81}{\sqrt{x} - 3} &= \lim_{x \rightarrow 9} \frac{(x-9)(x+9)}{\sqrt{x} - 3} = \lim_{x \rightarrow 9} \frac{(\sqrt{x}-3)(\sqrt{x}+3)(x+9)}{\sqrt{x} - 3} \quad \left[\begin{array}{l} \text{factor } x-9 \text{ as a} \\ \text{difference of squares} \end{array} \right] \\
 &= \lim_{x \rightarrow 9} [(\sqrt{x}+3)(x+9)] = (\sqrt{9}+3)(9+9) = 6 \cdot 18 = 108
 \end{aligned}$$

$$\begin{aligned}
 28. \lim_{h \rightarrow 0} \frac{(3+h)^{-1} - 3^{-1}}{h} &= \lim_{h \rightarrow 0} \frac{\frac{1}{3+h} - \frac{1}{3}}{h} = \lim_{h \rightarrow 0} \frac{3 - (3+h)}{h(3+h)3} = \lim_{h \rightarrow 0} \frac{-h}{h(3+h)3} \\
 &= \lim_{h \rightarrow 0} \left[-\frac{1}{3(3+h)} \right] = -\frac{1}{\lim_{h \rightarrow 0} [3(3+h)]} = -\frac{1}{3(3+0)} = -\frac{1}{9}
 \end{aligned}$$

$$\begin{aligned}
 29. \lim_{t \rightarrow 0} \left(\frac{1}{t\sqrt{1+t}} - \frac{1}{t} \right) &= \lim_{t \rightarrow 0} \frac{1 - \sqrt{1+t}}{t\sqrt{1+t}} = \lim_{t \rightarrow 0} \frac{(1 - \sqrt{1+t})(1 + \sqrt{1+t})}{t\sqrt{1+t}(1 + \sqrt{1+t})} = \lim_{t \rightarrow 0} \frac{-t}{t\sqrt{1+t}(1 + \sqrt{1+t})} \\
 &= \lim_{t \rightarrow 0} \frac{-1}{\sqrt{1+t}(1 + \sqrt{1+t})} = \frac{-1}{\sqrt{1+0}(1 + \sqrt{1+0})} = -\frac{1}{2}
 \end{aligned}$$

$$\begin{aligned}
 30. \lim_{x \rightarrow 1} \frac{\sqrt{x} - x^2}{1 - \sqrt{x}} &= \lim_{x \rightarrow 1} \frac{\sqrt{x}(1 - x^{3/2})}{1 - \sqrt{x}} = \lim_{x \rightarrow 1} \frac{\sqrt{x}(1 - \sqrt{x})(1 + \sqrt{x} + x)}{1 - \sqrt{x}} \quad [\text{difference of cubes}] \\
 &= \lim_{x \rightarrow 1} [\sqrt{x}(1 + \sqrt{x} + x)] = \lim_{x \rightarrow 1} [1(1 + 1 + 1)] = 3
 \end{aligned}$$

Another method: We “add and subtract” 1 in the numerator, and then split up the fraction:

$$\begin{aligned}
 \lim_{x \rightarrow 1} \frac{\sqrt{x} - x^2}{1 - \sqrt{x}} &= \lim_{x \rightarrow 1} \frac{(\sqrt{x} - 1) + (1 - x^2)}{1 - \sqrt{x}} = \lim_{x \rightarrow 1} \left[-1 + \frac{(1 - x)(1 + x)}{1 - \sqrt{x}} \right] \\
 &= \lim_{x \rightarrow 1} \left[-1 + \frac{(1 - \sqrt{x})(1 + \sqrt{x})(1 + x)}{1 - \sqrt{x}} \right] = -1 + (1 + \sqrt{1})(1 + 1) = 3
 \end{aligned}$$

31. (a)

$$\lim_{x \rightarrow 0} \frac{x}{\sqrt{1+3x}-1} \approx \frac{2}{3}$$

(b)

x	$f(x)$
-0.001	0.6661663
-0.0001	0.6666167
-0.00001	0.6666617
-0.000001	0.6666662
0.000001	0.6666672
0.00001	0.6666717
0.0001	0.6667167
0.001	0.6671663

The limit appears to be $\frac{2}{3}$.

$$\begin{aligned}
 (c) \lim_{x \rightarrow 0} \left(\frac{x}{\sqrt{1+3x}-1} \cdot \frac{\sqrt{1+3x}+1}{\sqrt{1+3x}+1} \right) &= \lim_{x \rightarrow 0} \frac{x(\sqrt{1+3x}+1)}{(1+3x)-1} = \lim_{x \rightarrow 0} \frac{x(\sqrt{1+3x}+1)}{3x} \\
 &= \frac{1}{3} \lim_{x \rightarrow 0} (\sqrt{1+3x}+1) \quad [\text{Limit Law 3}] \\
 &= \frac{1}{3} \left[\lim_{x \rightarrow 0} (\sqrt{1+3x}) + \lim_{x \rightarrow 0} 1 \right] \quad [1 \text{ and } 11] \\
 &= \frac{1}{3} \left(\sqrt{\lim_{x \rightarrow 0} 1 + 3 \lim_{x \rightarrow 0} x} + 1 \right) \quad [1, 3, \text{ and } 7] \\
 &= \frac{1}{3} (\sqrt{1+3 \cdot 0} + 1) \quad [7 \text{ and } 8] \\
 &= \frac{1}{3} (1 + 1) = \frac{2}{3}
 \end{aligned}$$

32. (a)

$$\lim_{x \rightarrow 0} \frac{\sqrt{3+x} - \sqrt{3}}{x} \approx 0.29$$

(b)

x	$f(x)$
-0.001	0.2886992
-0.0001	0.2886775
-0.00001	0.2886754
-0.000001	0.2886752
0.000001	0.2886751
0.00001	0.2886749
0.0001	0.2886727
0.001	0.2886511

The limit appears to be approximately 0.2887.

$$\begin{aligned}
 \text{(c)} \quad \lim_{x \rightarrow 0} \left(\frac{\sqrt{3+x} - \sqrt{3}}{x} \cdot \frac{\sqrt{3+x} + \sqrt{3}}{\sqrt{3+x} + \sqrt{3}} \right) &= \lim_{x \rightarrow 0} \frac{(3+x) - 3}{x(\sqrt{3+x} + \sqrt{3})} = \lim_{x \rightarrow 0} \frac{1}{\sqrt{3+x} + \sqrt{3}} \\
 &= \frac{\lim_{x \rightarrow 0} 1}{\lim_{x \rightarrow 0} \sqrt{3+x} + \lim_{x \rightarrow 0} \sqrt{3}} && \text{[Limit Laws 5 and 1]} \\
 &= \frac{1}{\sqrt{\lim_{x \rightarrow 0} (3+x)} + \sqrt{3}} && \text{[7 and 11]} \\
 &= \frac{1}{\sqrt{3+0} + \sqrt{3}} && \text{[1, 7, and 8]} \\
 &= \frac{1}{2\sqrt{3}}
 \end{aligned}$$

33. Let $f(x) = -x^2$, $g(x) = x^2 \cos 20\pi x$ and $h(x) = x^2$. Then

$$\begin{aligned}
 -1 \leq \cos 20\pi x \leq 1 &\Rightarrow -x^2 \leq x^2 \cos 20\pi x \leq x^2 \Rightarrow \\
 f(x) \leq g(x) \leq h(x). &\text{ So since } \lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} h(x) = 0, \text{ by the} \\
 \text{Squeeze Theorem we have } \lim_{x \rightarrow 0} g(x) &= 0.
 \end{aligned}$$

34. Let $f(x) = -\sqrt{x^3 + x^2}$, $g(x) = \sqrt{x^3 + x^2} \sin(\pi/x)$, and

$$\begin{aligned}
 h(x) &= \sqrt{x^3 + x^2}. \text{ Then } -1 \leq \sin(\pi/x) \leq 1 \Rightarrow \\
 -\sqrt{x^3 + x^2} &\leq \sqrt{x^3 + x^2} \sin(\pi/x) \leq \sqrt{x^3 + x^2} \Rightarrow \\
 f(x) \leq g(x) \leq h(x). &\text{ So since } \lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} h(x) = 0, \text{ by the} \\
 \text{Squeeze Theorem we have } \lim_{x \rightarrow 0} g(x) &= 0.
 \end{aligned}$$

35. $1 \leq f(x) \leq x^2 + 2x + 2$ for all x . Now $\lim_{x \rightarrow -1} 1 = 1$ and

$$\begin{aligned}
 \lim_{x \rightarrow -1} (x^2 + 2x + 2) &= \lim_{x \rightarrow -1} x^2 + 2 \lim_{x \rightarrow -1} x + \lim_{x \rightarrow -1} 2 = (-1)^2 + 2(-1) + 2 = 1. \text{ Therefore, by the Squeeze} \\
 \text{Theorem, } \lim_{x \rightarrow -1} f(x) &= 1.
 \end{aligned}$$

36. $3x \leq f(x) \leq x^3 + 2$ for $0 \leq x \leq 2$. Now $\lim_{x \rightarrow 1} 3x = 3$ and $\lim_{x \rightarrow 1} (x^3 + 2) = \lim_{x \rightarrow 1} x^3 + \lim_{x \rightarrow 1} 2 = 1^3 + 2 = 3$.

Therefore, by the Squeeze Theorem, $\lim_{x \rightarrow 1} f(x) = 3$.

37. $-1 \leq \cos(2/x) \leq 1 \Rightarrow -x^4 \leq x^4 \cos(2/x) \leq x^4$. Since $\lim_{x \rightarrow 0} (-x^4) = 0$ and $\lim_{x \rightarrow 0} x^4 = 0$, we have

$\lim_{x \rightarrow 0} [x^4 \cos(2/x)] = 0$ by the Squeeze Theorem.

38. $-1 \leq \sin(2\pi/x) \leq 1 \Rightarrow 0 \leq \sin^2(2\pi/x) \leq 1 \Rightarrow 1 \leq 1 + \sin^2(2\pi/x) \leq 2 \Rightarrow$

$\sqrt{x} \leq \sqrt{x} [1 + \sin^2(2\pi/x)] \leq 2\sqrt{x}$. Since $\lim_{x \rightarrow 0^+} \sqrt{x} = 0$ and $\lim_{x \rightarrow 0^+} 2\sqrt{x} = 0$, we have

$\lim_{x \rightarrow 0^+} [\sqrt{x} (1 + \sin^2(2\pi/x))] = 0$ by the Squeeze Theorem.

39. If $x > -4$, then $|x + 4| = x + 4$, so $\lim_{x \rightarrow -4^+} |x + 4| = \lim_{x \rightarrow -4^+} (x + 4) = -4 + 4 = 0$.

If $x < -4$, then $|x + 4| = -(x + 4)$, so $\lim_{x \rightarrow -4^-} |x + 4| = \lim_{x \rightarrow -4^-} -(x + 4) = -(-4 + 4) = 0$.

Since the right and left limits are equal, $\lim_{x \rightarrow -4} |x + 4| = 0$.

40. If $x < -4$, then $|x + 4| = -(x + 4)$, so $\lim_{x \rightarrow -4^-} \frac{|x + 4|}{x + 4} = \lim_{x \rightarrow -4^-} \frac{-(x + 4)}{x + 4} = \lim_{x \rightarrow -4^-} (-1) = -1$.

41. If $x > 2$, then $|x - 2| = x - 2$, so $\lim_{x \rightarrow 2^+} \frac{|x - 2|}{x - 2} = \lim_{x \rightarrow 2^+} \frac{x - 2}{x - 2} = \lim_{x \rightarrow 2^+} 1 = 1$. If $x < 2$, then

$|x - 2| = -(x - 2)$, so $\lim_{x \rightarrow 2^-} \frac{|x - 2|}{x - 2} = \lim_{x \rightarrow 2^-} \frac{-(x - 2)}{x - 2} = \lim_{x \rightarrow 2^-} -1 = -1$. The right and left limits are

different, so $\lim_{x \rightarrow 2} \frac{|x - 2|}{x - 2}$ does not exist.

42. If $x > \frac{3}{2}$, then $|2x - 3| = 2x - 3$, so

$\lim_{x \rightarrow 1.5^+} \frac{2x^2 - 3x}{|2x - 3|} = \lim_{x \rightarrow 1.5^+} \frac{2x^2 - 3x}{2x - 3} = \lim_{x \rightarrow 1.5^+} \frac{x(2x - 3)}{2x - 3} = \lim_{x \rightarrow 1.5^+} x = 1.5$. If $x < \frac{3}{2}$, then

$|2x - 3| = 3 - 2x$, so $\lim_{x \rightarrow 1.5^-} \frac{2x^2 - 3x}{|2x - 3|} = \lim_{x \rightarrow 1.5^-} \frac{2x^2 - 3x}{-(2x - 3)} = \lim_{x \rightarrow 1.5^-} \frac{x(2x - 3)}{-(2x - 3)} = \lim_{x \rightarrow 1.5^-} -x = -1.5$.

The right and left limits are different, so $\lim_{x \rightarrow 1.5} \frac{2x^2 - 3x}{|2x - 3|}$ does not exist.

43. Since $|x| = -x$ for $x < 0$, we have $\lim_{x \rightarrow 0^-} \left(\frac{1}{x} - \frac{1}{|x|} \right) = \lim_{x \rightarrow 0^-} \left(\frac{1}{x} - \frac{1}{-x} \right) = \lim_{x \rightarrow 0^-} \frac{2}{x}$, which does not exist since the denominator approaches 0 and the numerator does not.

44. Since $|x| = x$ for $x > 0$, we have $\lim_{x \rightarrow 0^+} \left(\frac{1}{x} - \frac{1}{|x|} \right) = \lim_{x \rightarrow 0^+} \left(\frac{1}{x} - \frac{1}{x} \right) = \lim_{x \rightarrow 0^+} 0 = 0$.

45. (a)

- (b) (i) Since $\operatorname{sgn} x = 1$ for $x > 0$, $\lim_{x \rightarrow 0^+} \operatorname{sgn} x = \lim_{x \rightarrow 0^+} 1 = 1$.

- (ii) Since $\operatorname{sgn} x = -1$ for $x < 0$, $\lim_{x \rightarrow 0^-} \operatorname{sgn} x = \lim_{x \rightarrow 0^-} -1 = -1$.

- (iii) Since $\lim_{x \rightarrow 0^-} \operatorname{sgn} x \neq \lim_{x \rightarrow 0^+} \operatorname{sgn} x$, $\lim_{x \rightarrow 0} \operatorname{sgn} x$ does not exist.

- (iv) Since $|\operatorname{sgn} x| = 1$ for $x \neq 0$, $\lim_{x \rightarrow 0} |\operatorname{sgn} x| = \lim_{x \rightarrow 0} 1 = 1$.

$$46. (a) \lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} (4 - x^2) = \lim_{x \rightarrow 2^-} 4 - \lim_{x \rightarrow 2^-} x^2 = 4 - 4 = 0$$

$$\lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} (x - 1) = \lim_{x \rightarrow 2^+} x - \lim_{x \rightarrow 2^+} 1 = 2 - 1 = 1$$

(b) No, $\lim_{x \rightarrow 2} f(x)$ does not exist since $\lim_{x \rightarrow 2^-} f(x) \neq \lim_{x \rightarrow 2^+} f(x)$.

(c)

$$47. (a) (i) \lim_{x \rightarrow 1^+} \frac{x^2 - 1}{|x - 1|} = \lim_{x \rightarrow 1^+} \frac{x^2 - 1}{x - 1} = \lim_{x \rightarrow 1^+} (x + 1) = 2$$

$$(ii) \lim_{x \rightarrow 1^-} \frac{x^2 - 1}{|x - 1|} = \lim_{x \rightarrow 1^-} \frac{x^2 - 1}{-(x - 1)} = \lim_{x \rightarrow 1^-} -(x + 1) = -2$$

(b) No, $\lim_{x \rightarrow 1} F(x)$ does not exist since $\lim_{x \rightarrow 1^+} F(x) \neq \lim_{x \rightarrow 1^-} F(x)$.

(c)

$$48. (a) (i) \lim_{x \rightarrow 0^+} h(x) = \lim_{x \rightarrow 0^+} x^2 = 0^2 = 0$$

$$(ii) \lim_{x \rightarrow 0^-} h(x) = \lim_{x \rightarrow 0^-} x = 0, \text{ so } \lim_{x \rightarrow 0} h(x) = 0.$$

$$(iii) \lim_{x \rightarrow 1} h(x) = \lim_{x \rightarrow 1} x^2 = 1^2 = 1$$

$$(iv) \lim_{x \rightarrow 2^-} h(x) = \lim_{x \rightarrow 2^-} x^2 = 2^2 = 4$$

$$(v) \lim_{x \rightarrow 2^+} h(x) = \lim_{x \rightarrow 2^+} (8 - x) = 8 - 2 = 6$$

(vi) Since $\lim_{x \rightarrow 2^-} h(x) \neq \lim_{x \rightarrow 2^+} h(x)$, $\lim_{x \rightarrow 2} h(x)$ does not exist.

(b)

$$49. (a) (i) \lfloor x \rfloor = -2 \text{ for } -2 \leq x < -1, \text{ so } \lim_{x \rightarrow -2^+} \lfloor x \rfloor = \lim_{x \rightarrow -2^+} (-2) = -2$$

(ii) $\lfloor x \rfloor = -3$ for $-3 \leq x < -2$, so $\lim_{x \rightarrow -2^-} \lfloor x \rfloor = \lim_{x \rightarrow -2^-} (-3) = -3$. The right and left limits are different, so $\lim_{x \rightarrow -2} \lfloor x \rfloor$ does not exist.

$$(iii) \lfloor x \rfloor = -3 \text{ for } -3 \leq x < -2, \text{ so } \lim_{x \rightarrow -2.4} \lfloor x \rfloor = \lim_{x \rightarrow -2.4} (-3) = -3.$$

$$(b) (i) \lfloor x \rfloor = n - 1 \text{ for } n - 1 \leq x < n, \text{ so } \lim_{x \rightarrow n^-} \lfloor x \rfloor = \lim_{x \rightarrow n^-} (n - 1) = n - 1.$$

$$(ii) \lfloor x \rfloor = n \text{ for } n \leq x < n + 1, \text{ so } \lim_{x \rightarrow n^+} \lfloor x \rfloor = \lim_{x \rightarrow n^+} n = n.$$

(c) $\lim_{x \rightarrow a} \lfloor x \rfloor$ exists $\Leftrightarrow a$ is not an integer.

50. (a)

$$(b) (i) \lim_{x \rightarrow n^-} f(x) = \lim_{x \rightarrow n^-} (x - \lfloor x \rfloor) = \lim_{x \rightarrow n^-} [x - (n - 1)] = n - (n - 1) = 1$$

$$(ii) \lim_{x \rightarrow n^+} f(x) = \lim_{x \rightarrow n^+} (x - \lfloor x \rfloor) = \lim_{x \rightarrow n^+} (x - n) = n - n = 0$$

(c) $\lim_{x \rightarrow a} f(x)$ exists $\Leftrightarrow a$ is not an integer.

51. The graph of $f(x) = \lfloor x \rfloor + \lfloor -x \rfloor$ is the same as the graph of $g(x) = -1$ with holes at each integer, since $f(a) = 0$ for any integer a . Thus, $\lim_{x \rightarrow 2^-} f(x) = -1$ and $\lim_{x \rightarrow 2^+} f(x) = -1$, so $\lim_{x \rightarrow 2} f(x) = -1$. However, $f(2) = \lfloor 2 \rfloor + \lfloor -2 \rfloor = 2 + (-2) = 0$, so $\lim_{x \rightarrow 2} f(x) \neq f(2)$.

52. $\lim_{v \rightarrow c^-} \left(L_0 \sqrt{1 - \frac{v^2}{c^2}} \right) = L_0 \sqrt{1 - 1} = 0$. As the velocity approaches the speed of light, the length approaches 0. A left-hand limit is necessary since L is not defined for $v > c$.

53. Since $p(x)$ is a polynomial, $p(x) = a_0 + a_1x + a_2x^2 + \cdots + a_nx^n$. Thus, by the Limit Laws,

$$\begin{aligned} \lim_{x \rightarrow a} p(x) &= \lim_{x \rightarrow a} (a_0 + a_1x + a_2x^2 + \cdots + a_nx^n) \\ &= a_0 + a_1 \lim_{x \rightarrow a} x + a_2 \lim_{x \rightarrow a} x^2 + \cdots + a_n \lim_{x \rightarrow a} x^n \\ &= a_0 + a_1a + a_2a^2 + \cdots + a_na^n = p(a) \end{aligned}$$

Thus, for any polynomial p , $\lim_{x \rightarrow a} p(x) = p(a)$.

54. Let $r(x) = \frac{p(x)}{q(x)}$ where $p(x)$ and $q(x)$ are any polynomials, and suppose that $q(a) \neq 0$. Thus,

$$\lim_{x \rightarrow a} r(x) = \lim_{x \rightarrow a} \frac{p(x)}{q(x)} = \frac{\lim_{x \rightarrow a} p(x)}{\lim_{x \rightarrow a} q(x)} \quad [\text{Limit Law 5}] = \frac{p(a)}{q(a)} \quad [\text{Exercise 53}] = r(a).$$

55. Observe that $0 \leq f(x) \leq x^2$ for all x , and $\lim_{x \rightarrow 0} 0 = 0 = \lim_{x \rightarrow 0} x^2$. So, by the Squeeze Theorem, $\lim_{x \rightarrow 0} f(x) = 0$.

56. Let $f(x) = \lfloor x \rfloor$ and $g(x) = -\lfloor x \rfloor$. Then $\lim_{x \rightarrow 3} f(x)$ and $\lim_{x \rightarrow 3} g(x)$ do not exist (Example 10) but

$$\lim_{x \rightarrow 3} [f(x) + g(x)] = \lim_{x \rightarrow 3} (\lfloor x \rfloor - \lfloor x \rfloor) = \lim_{x \rightarrow 3} 0 = 0.$$

57. Let $f(x) = H(x)$ and $g(x) = 1 - H(x)$, where H is the Heaviside function defined in Exercise 1.3.59.

Thus, either f or g is 0 for any value of x . Then $\lim_{x \rightarrow 0} f(x)$ and $\lim_{x \rightarrow 0} g(x)$ do not exist, but

$$\lim_{x \rightarrow 0} [f(x)g(x)] = \lim_{x \rightarrow 0} 0 = 0.$$

58.
$$\begin{aligned} \lim_{x \rightarrow 2} \frac{\sqrt{6-x}-2}{\sqrt{3-x}-1} &= \lim_{x \rightarrow 2} \left(\frac{\sqrt{6-x}-2}{\sqrt{3-x}-1} \cdot \frac{\sqrt{6-x}+2}{\sqrt{6-x}+2} \cdot \frac{\sqrt{3-x}+1}{\sqrt{3-x}+1} \right) \\ &= \lim_{x \rightarrow 2} \left[\frac{(\sqrt{6-x})^2 - 2^2}{(\sqrt{3-x})^2 - 1^2} \cdot \frac{\sqrt{3-x}+1}{\sqrt{6-x}+2} \right] = \lim_{x \rightarrow 2} \left(\frac{6-x-4}{3-x-1} \cdot \frac{\sqrt{3-x}+1}{\sqrt{6-x}+2} \right) \\ &= \lim_{x \rightarrow 2} \frac{(2-x)(\sqrt{3-x}+1)}{(2-x)(\sqrt{6-x}+2)} = \lim_{x \rightarrow 2} \frac{\sqrt{3-x}+1}{\sqrt{6-x}+2} = \frac{1}{2} \end{aligned}$$

59. Since the denominator approaches 0 as $x \rightarrow -2$, the limit will exist only if the numerator also approaches 0 as $x \rightarrow -2$. In order for this to happen, we need $\lim_{x \rightarrow -2} (3x^2 + ax + a + 3) = 0 \Leftrightarrow$

$$3(-2)^2 + a(-2) + a + 3 = 0 \Leftrightarrow 12 - 2a + a + 3 = 0 \Leftrightarrow a = 15. \text{ With } a = 15, \text{ the limit becomes}$$

$$\lim_{x \rightarrow -2} \frac{3x^2 + 15x + 18}{x^2 + x - 2} = \lim_{x \rightarrow -2} \frac{3(x+2)(x+3)}{(x-1)(x+2)} = \lim_{x \rightarrow -2} \frac{3(x+3)}{x-1} = \frac{3(-2+3)}{-2-1} = \frac{3}{-3} = -1.$$

60. Solution 1: First, we find the coordinates of P and Q as functions of r . Then we can find the equation of the line determined by these two points, and thus find the x -intercept (the point R), and take the limit as $r \rightarrow 0$.

The coordinates of P are $(0, r)$. The point Q is the point of intersection of the two circles $x^2 + y^2 = r^2$ and $(x - 1)^2 + y^2 = 1$. Eliminating y from these equations, we get $r^2 - x^2 = 1 - (x - 1)^2 \Leftrightarrow r^2 = 1 + 2x - 1 \Leftrightarrow x = \frac{1}{2}r^2$. Substituting back into the equation of the shrinking circle to find the y -coordinate, we get

$(\frac{1}{2}r^2)^2 + y^2 = r^2 \Leftrightarrow y^2 = r^2(1 - \frac{1}{4}r^2) \Leftrightarrow y = r\sqrt{1 - \frac{1}{4}r^2}$ (the positive y -value). So the coordinates of Q are $(\frac{1}{2}r^2, r\sqrt{1 - \frac{1}{4}r^2})$. The equation of the line joining P and Q is thus

$y - r = \frac{r\sqrt{1 - \frac{1}{4}r^2} - r}{\frac{1}{2}r^2 - 0}(x - 0)$. We set $y = 0$ in order to find the x -intercept, and get

$$x = -r \frac{\frac{1}{2}r^2}{r(\sqrt{1 - \frac{1}{4}r^2} - 1)} = \frac{-\frac{1}{2}r^2(\sqrt{1 - \frac{1}{4}r^2} + 1)}{1 - \frac{1}{4}r^2 - 1} = 2\left(\sqrt{1 - \frac{1}{4}r^2} + 1\right).$$

Now we take the limit as $r \rightarrow 0^+$: $\lim_{r \rightarrow 0^+} x = \lim_{r \rightarrow 0^+} 2\left(\sqrt{1 - \frac{1}{4}r^2} + 1\right) = \lim_{r \rightarrow 0^+} 2(\sqrt{1} + 1) = 4$.

So the limiting position of R is the point $(4, 0)$.

Solution 2: We add a few lines to the diagram, as shown. Note that $\angle PQS = 90^\circ$ (subtended by diameter PS).

So $\angle SQR = 90^\circ = \angle OQT$ (subtended by diameter OT). It follows that $\angle OQS = \angle TQR$. Also

$\angle PSQ = 90^\circ - \angle SPQ = \angle ORP$. Since $\triangle QOS$ is isosceles, so is $\triangle QTR$, implying that $QT = TR$. As the circle C_2 shrinks, the point Q plainly approaches the origin, so the point R must approach a point twice as far from the origin as T , that is, the point $(4, 0)$, as above.

2.4 The Precise Definition of a Limit

1. (a) To have $5x + 3$ within a distance of 0.1 of 13, we must have $12.9 \leq 5x + 3 \leq 13.1 \Rightarrow 9.9 \leq 5x \leq 10.1 \Rightarrow 1.98 \leq x \leq 2.02$. Thus, x must be within 0.02 units of 2 so that $5x + 3$ is within 0.1 of 13.
 (b) Use 0.01 in place of 0.1 in part (a) to obtain 0.002.
2. (a) To have $6x - 1$ within a distance of 0.01 of 29, we must have $28.99 \leq 6x - 1 \leq 29.01 \Rightarrow 29.99 \leq 6x \leq 30.01 \Rightarrow 4.998\bar{3} \leq x \leq 5.001\bar{6}$. Thus, x must be within $0.001\bar{6}$ units of 5 so that $6x - 1$ is within 0.01 of 29.
 (b) As in part (a) with 0.001 in place of 0.01, we obtain $0.0001\bar{6}$.
 (c) As in part (a) with 0.0001 in place of 0.01, we obtain $0.00001\bar{6}$.

3. On the left side of $x = 2$, we need $|x - 2| < \left| \frac{10}{7} - 2 \right| = \frac{4}{7}$. On the right side, we need $|x - 2| < \left| \frac{10}{3} - 2 \right| = \frac{4}{3}$. For both of these conditions to be satisfied at once, we need the more restrictive of the two to hold, that is, $|x - 2| < \frac{4}{7}$. So we can choose $\delta = \frac{4}{7}$, or any smaller positive number.
4. On the left side, we need $|x - 5| < |4 - 5| = 1$. On the right side, we need $|x - 5| < |5.7 - 5| = 0.7$. For both conditions to be satisfied at once, we need the more restrictive condition to hold; that is, $|x - 5| < 0.7$. So we can choose $\delta = 0.7$, or any smaller positive number.
5. The leftmost question mark is the solution of $\sqrt{x} = 1.6$ and the rightmost, $\sqrt{x} = 2.4$. So the values are $1.6^2 = 2.56$ and $2.4^2 = 5.76$. On the left side, we need $|x - 4| < |2.56 - 4| = 1.44$. On the right side, we need $|x - 4| < |5.76 - 4| = 1.76$. To satisfy both conditions, we need the more restrictive condition to hold — namely, $|x - 4| < 1.44$. Thus, we can choose $\delta = 1.44$, or any smaller positive number.
6. The left-hand question mark is the positive solution of $x^2 = \frac{1}{2}$, that is, $x = \frac{1}{\sqrt{2}}$, and the right-hand question mark is the positive solution of $x^2 = \frac{3}{2}$, that is, $x = \sqrt{\frac{3}{2}}$. On the left side, we need $|x - 1| < \left| \frac{1}{\sqrt{2}} - 1 \right| \approx 0.292$ (rounding down to be safe). On the right side, we need $|x - 1| < \left| \sqrt{\frac{3}{2}} - 1 \right| \approx 0.224$. The more restrictive of these two conditions must apply, so we choose $\delta = 0.224$ (or any smaller positive number).
7. $|\sqrt{4x+1} - 3| < 0.5 \Leftrightarrow 2.5 < \sqrt{4x+1} < 3.5$. We plot the three parts of this inequality on the same screen and identify the x -coordinates of the points of intersection using the cursor. It appears that the inequality holds for $1.3125 \leq x \leq 2.8125$. Since $|2 - 1.3125| = 0.6875$ and $|2 - 2.8125| = 0.8125$, we choose $0 < \delta < \min \{0.6875, 0.8125\} = 0.6875$.
8. $|\sin x - \frac{1}{2}| < 0.1 \Leftrightarrow 0.4 < \sin x < 0.6$. From the graph, we see that for this inequality to hold, we need $0.42 \leq x \leq 0.64$. So since $|0.5 - 0.42| = 0.08$ and $|0.5 - 0.64| = 0.14$, we choose $0 < \delta \leq \min \{0.08, 0.14\} = 0.08$.

9. For $\varepsilon = 1$, the definition of a limit requires that we find δ such that $|(4 + x - 3x^3) - 2| < 1 \Leftrightarrow$

$1 < 4 + x - 3x^3 < 3$ whenever $0 < |x - 1| < \delta$. If we plot the graphs of $y = 1$, $y = 4 + x - 3x^3$ and $y = 3$ on the same screen, we see that we need $0.86 \leq x \leq 1.11$. So since $|1 - 0.86| = 0.14$ and $|1 - 1.11| = 0.11$, we choose $\delta = 0.11$ (or any smaller positive number). For $\varepsilon = 0.1$, we must find δ such that

$|(4 + x - 3x^3) - 2| < 0.1 \Leftrightarrow 1.9 < 4 + x - 3x^3 < 2.1$ whenever $0 < |x - 1| < \delta$. From the graph, we see that we need $0.988 \leq x \leq 1.012$. So since $|1 - 0.988| = 0.012$ and $|1 - 1.012| = 0.012$, we choose $\delta = 0.012$ (or any smaller positive number) for the inequality to hold.

10. For $\varepsilon = 0.5$, we need $1.91 \leq x \leq 2.125$. So since $|2 - 1.91| = 0.09$ and $|2 - 2.125| = 0.125$, we can take $0 < \delta \leq 0.09$. For $\varepsilon = 0.1$, we need $1.980 \leq x \leq 2.021$. So since $|2 - 1.980| = 0.02$ and $|2 - 2.021| = 0.021$, we can take $\delta = 0.02$ (or any smaller positive number).

11. From the graph, we see that $\frac{x}{(x^2 + 1)(x - 1)^2} > 100$ whenever $0.93 \leq x \leq 1.07$. So since $|1 - 0.93| = 0.07$ and $|1 - 1.07| = 0.07$, we can take $\delta = 0.07$ (or any smaller positive number).

12. For $M = 100$, we need $-0.0997 < x < 0$ or $0 < x < 0.0997$. Thus, we choose $\delta = 0.0997$ (or any smaller positive number) so that if $0 < |x| < \delta$, then $\cot^2 x > 100$.

For $M = 1000$, we need $-0.0316 < x < 0$ or $0 < x < 0.0316$. Thus, we choose $\delta = 0.0316$ (or any smaller positive number) so that if $0 < |x| < \delta$, then $\cot^2 x > 1000$.

13. (a) $A = \pi r^2$ and $A = 1000 \text{ cm}^2 \Rightarrow \pi r^2 = 1000 \Rightarrow r^2 = \frac{1000}{\pi} \Rightarrow$

$$r = \sqrt{\frac{1000}{\pi}} \quad [r > 0] \approx 17.8412 \text{ cm.}$$

(b) $|A - 1000| \leq 5 \Rightarrow -5 \leq \pi r^2 - 1000 \leq 5 \Rightarrow 1000 - 5 \leq \pi r^2 \leq 1000 + 5 \Rightarrow$

$$\sqrt{\frac{995}{\pi}} \leq r \leq \sqrt{\frac{1005}{\pi}} \Rightarrow 17.7966 \leq r \leq 17.8858. \quad \sqrt{\frac{1000}{\pi}} - \sqrt{\frac{995}{\pi}} \approx 0.04466 \text{ and}$$

$$\sqrt{\frac{1005}{\pi}} - \sqrt{\frac{1000}{\pi}} \approx 0.04455. \text{ So if the machinist gets the radius within } 0.0445 \text{ cm of } 17.8412, \text{ the area will be within } 5 \text{ cm}^2 \text{ of } 1000.$$

(c) x is the radius, $f(x)$ is the area, a is the target radius given in part (a), L is the target area (1000), ε is the tolerance in the area (5), and δ is the tolerance in the radius given in part (b).

14. (a) $T = 0.1w^2 + 2.155w + 20$ and $T = 200 \Rightarrow$

$$0.1w^2 + 2.155w + 20 = 200 \Rightarrow [\text{by the quadratic formula or from the graph}] \quad w \approx 33.0 \text{ watts } (w > 0)$$

(b) From the graph, $199 \leq T \leq 201 \Rightarrow 32.89 < w < 33.11$.

(c) x is the input power, $f(x)$ is the temperature, a is the target input power given in part (a), L is the target temperature (200), ε is the tolerance in the temperature (1), and δ is the tolerance in the power input in watts indicated in part (b) (0.11 watts).

15. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 1| < \delta$, then

$$|(2x + 3) - 5| < \varepsilon. \text{ But } |(2x + 3) - 5| < \varepsilon \Leftrightarrow |2x - 2| < \varepsilon$$

$$\Leftrightarrow 2|x - 1| < \varepsilon \Leftrightarrow |x - 1| < \varepsilon/2. \text{ So if we choose } \delta = \varepsilon/2,$$

$$\text{then } 0 < |x - 1| < \delta \Rightarrow |(2x + 3) - 5| < \varepsilon. \text{ Thus,}$$

$$\lim_{x \rightarrow 1} (2x + 3) = 5 \text{ by the definition of a limit.}$$

16. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - (-2)| < \delta$, then

$$\left| \left(\frac{1}{2}x + 3 \right) - 2 \right| < \varepsilon. \text{ But } \left| \left(\frac{1}{2}x + 3 \right) - 2 \right| < \varepsilon \Leftrightarrow$$

$$\left| \frac{1}{2}x + 1 \right| < \varepsilon \Leftrightarrow \frac{1}{2}|x + 2| < \varepsilon \Leftrightarrow |x - (-2)| < 2\varepsilon. \text{ So if}$$

we choose $\delta = 2\varepsilon$, then $0 < |x - (-2)| < \delta \Rightarrow$

$$\left| \left(\frac{1}{2}x + 3 \right) - 2 \right| < \varepsilon. \text{ Thus, } \lim_{x \rightarrow -2} \left(\frac{1}{2}x + 3 \right) = 2 \text{ by the definition of a}$$

limit.

17. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - (-3)| < \delta$, then

$$|(1 - 4x) - 13| < \varepsilon. \text{ But } |(1 - 4x) - 13| < \varepsilon \Leftrightarrow$$

$$|-4x - 12| < \varepsilon \Leftrightarrow |-4||x + 3| < \varepsilon \Leftrightarrow |x - (-3)| < \varepsilon/4.$$

So if we choose $\delta = \varepsilon/4$, then $0 < |x - (-3)| < \delta \Rightarrow$

$$|(1 - 4x) - 13| < \varepsilon. \text{ Thus, } \lim_{x \rightarrow -3} (1 - 4x) = 13 \text{ by the definition of}$$

a limit.

18. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 4| < \delta$, then

$$|(7 - 3x) - (-5)| < \varepsilon. \text{ But } |(7 - 3x) - (-5)| < \varepsilon \Leftrightarrow$$

$$|-3x + 12| < \varepsilon \Leftrightarrow |-3||x - 4| < \varepsilon \Leftrightarrow |x - 4| < \varepsilon/3. \text{ So}$$

if we choose $\delta = \varepsilon/3$, then $0 < |x - 4| < \delta \Rightarrow$

$$|(7 - 3x) - (-5)| < \varepsilon. \text{ Thus, } \lim_{x \rightarrow 4} (7 - 3x) = -5 \text{ by the definition}$$

of a limit.

19. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 3| < \delta$, then $\left| \frac{x}{5} - \frac{3}{5} \right| < \varepsilon \Leftrightarrow \frac{1}{5}|x - 3| < \varepsilon \Leftrightarrow$

$$|x - 3| < 5\varepsilon. \text{ So choose } \delta = 5\varepsilon. \text{ Then } 0 < |x - 3| < \delta \Rightarrow |x - 3| < 5\varepsilon \Rightarrow \frac{|x - 3|}{5} < \varepsilon \Rightarrow$$

$$\left| \frac{x}{5} - \frac{3}{5} \right| < \varepsilon. \text{ By the definition of a limit, } \lim_{x \rightarrow 3} \frac{x}{5} = \frac{3}{5}.$$

20. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 6| < \delta$, then $\left| \left(\frac{x}{4} + 3 \right) - \frac{9}{2} \right| < \varepsilon \Leftrightarrow \left| \frac{x}{4} - \frac{3}{2} \right| < \varepsilon \Leftrightarrow$

$$\frac{1}{4}|x - 6| < \varepsilon \Leftrightarrow |x - 6| < 4\varepsilon. \text{ So choose } \delta = 4\varepsilon. \text{ Then } 0 < |x - 6| < \delta \Rightarrow |x - 6| < 4\varepsilon \Rightarrow$$

$$\frac{|x - 6|}{4} < \varepsilon \Rightarrow \left| \frac{x}{4} - \frac{6}{4} \right| < \varepsilon \Rightarrow \left| \left(\frac{x}{4} + 3 \right) - \frac{9}{2} \right| < \varepsilon. \text{ By the definition of a limit, } \lim_{x \rightarrow 6} \left(\frac{x}{4} + 3 \right) = \frac{9}{2}.$$

21. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - (-5)| < \delta$, then $\left| \left(4 - \frac{3}{5}x \right) - 7 \right| < \varepsilon \Leftrightarrow$

$$\left| -\frac{3}{5}x - 3 \right| < \varepsilon \Leftrightarrow \frac{3}{5}|x + 5| < \varepsilon \Leftrightarrow |x - (-5)| < \frac{5}{3}\varepsilon. \text{ So choose } \delta = \frac{5}{3}\varepsilon. \text{ Then } |x - (-5)| < \delta \Rightarrow$$

$$\left| \left(4 - \frac{3}{5}x \right) - 7 \right| < \varepsilon. \text{ Thus, } \lim_{x \rightarrow -5} \left(4 - \frac{3}{5}x \right) = 7 \text{ by the definition of a limit.}$$

22. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 3| < \delta$, then $\left| \frac{x^2 + x - 12}{x - 3} - 7 \right| < \varepsilon$. Notice that if $0 < |x - 3|$, then $x \neq 3$, so $\frac{x^2 + x - 12}{x - 3} = \frac{(x + 4)(x - 3)}{x - 3} = x + 4$. Thus, when $0 < |x - 3|$, we have
- $$\left| \frac{x^2 + x - 12}{x - 3} - 7 \right| < \varepsilon \Leftrightarrow |(x + 4) - 7| < \varepsilon \Leftrightarrow |x - 3| < \varepsilon.$$
- We take $\delta = \varepsilon$ and see that $0 < |x - 3| < \delta$
- $$\Rightarrow \left| \frac{x^2 + x - 12}{x - 3} - 7 \right| < \varepsilon.$$
- By the definition of a limit, $\lim_{x \rightarrow 3} \frac{x^2 + x - 12}{x - 3} = 7$.
23. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - a| < \delta$, then $|x - a| < \varepsilon$. So $\delta = \varepsilon$ will work.
24. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - a| < \delta$, then $|c - c| < \varepsilon$. But $|c - c| = 0$, so this will be true no matter what δ we pick.
25. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 0| < \delta$, then $|x^2 - 0| < \varepsilon \Leftrightarrow x^2 < \varepsilon \Leftrightarrow |x| < \sqrt{\varepsilon}$. Take $\delta = \sqrt{\varepsilon}$. Then $0 < |x - 0| < \delta \Rightarrow |x^2 - 0| < \varepsilon$. Thus, $\lim_{x \rightarrow 0} x^2 = 0$ by the definition of a limit.
26. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 0| < \delta$, then $|x^3 - 0| < \varepsilon \Leftrightarrow |x|^3 < \varepsilon \Leftrightarrow |x| < \sqrt[3]{\varepsilon}$. Take $\delta = \sqrt[3]{\varepsilon}$. Then $0 < |x - 0| < \delta \Rightarrow |x^3 - 0| < \varepsilon$. Thus, $\lim_{x \rightarrow 0} x^3 = 0$ by the definition of a limit.
27. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 0| < \delta$, then $||x| - 0| < \varepsilon$. But $||x|| = |x|$. So this is true if we pick $\delta = \varepsilon$. Thus, $\lim_{x \rightarrow 0} |x| = 0$ by the definition of a limit.
28. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $9 - \delta < x < 9$, then $|\sqrt[4]{9 - x} - 0| < \varepsilon \Leftrightarrow \sqrt[4]{9 - x} < \varepsilon \Leftrightarrow 9 - x < \varepsilon^4 \Leftrightarrow 9 - \varepsilon^4 < x < 9$. So take $\delta = \varepsilon^4$. Then $9 - \delta < x < 9 \Rightarrow |\sqrt[4]{9 - x} - 0| < \varepsilon$. Thus, $\lim_{x \rightarrow 9^-} \sqrt[4]{9 - x} = 0$ by the definition of a limit.
29. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 2| < \delta$, then $|(x^2 - 4x + 5) - 1| < \varepsilon \Leftrightarrow |x^2 - 4x + 4| < \varepsilon \Leftrightarrow |(x - 2)^2| < \varepsilon$. So take $\delta = \sqrt{\varepsilon}$. Then $0 < |x - 2| < \delta \Leftrightarrow |x - 2| < \sqrt{\varepsilon} \Leftrightarrow |(x - 2)^2| < \varepsilon$. Thus, $\lim_{x \rightarrow 2} (x^2 - 4x + 5) = 1$ by the definition of a limit.
30. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 3| < \delta$, then $|(x^2 + x - 4) - 8| < \varepsilon \Leftrightarrow |x^2 + x - 12| < \varepsilon \Leftrightarrow |(x - 3)(x + 4)| < \varepsilon$. Notice that if $|x - 3| < 1$, then $-1 < x - 3 < 1 \Rightarrow 6 < x + 4 < 8 \Rightarrow |x + 4| < 8$. So take $\delta = \min\{1, \varepsilon/8\}$. Then $0 < |x - 3| < \delta \Leftrightarrow |(x - 3)(x + 4)| \leq |8(x - 3)| = 8 \cdot |x - 3| < 8\delta \leq \varepsilon$. Thus, $\lim_{x \rightarrow 3} (x^2 + x - 4) = 8$ by the definition of a limit.
31. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - (-2)| < \delta$, then $|(x^2 - 1) - 3| < \varepsilon$ or upon simplifying we need $|x^2 - 4| < \varepsilon$ whenever $0 < |x + 2| < \delta$. Notice that if $|x + 2| < 1$, then $-1 < x + 2 < 1 \Rightarrow -5 < x - 2 < -3 \Rightarrow |x - 2| < 5$. So take $\delta = \min\{\varepsilon/5, 1\}$. Then $0 < |x + 2| < \delta \Rightarrow |x - 2| < 5$ and $|x + 2| < \varepsilon/5$, so $|(x^2 - 1) - 3| = |(x + 2)(x - 2)| = |x + 2||x - 2| < (\varepsilon/5)(5) = \varepsilon$. Thus, by the definition of a limit, $\lim_{x \rightarrow -2} (x^2 - 1) = 3$.
32. Given $\varepsilon > 0$, we need $\delta > 0$ such that if $0 < |x - 2| < \delta$, then $|x^3 - 8| < \varepsilon$. Now $|x^3 - 8| = |(x - 2)(x^2 + 2x + 4)|$. If $|x - 2| < 1$, that is, $1 < x < 3$, then $x^2 + 2x + 4 < 3^2 + 2(3) + 4 = 19$ and so $|x^3 - 8| = |x - 2|(x^2 + 2x + 4) < 19|x - 2|$. So if we take $\delta = \min\{1, \frac{\varepsilon}{19}\}$, then

$0 < |x - 2| < \delta \Rightarrow |x^3 - 8| = |x - 2|(x^2 + 2x + 4) < \frac{\epsilon}{19} \cdot 19 = \epsilon$. Thus, by the definition of a limit,
 $\lim_{x \rightarrow 2} x^3 = 8$.

33. Given $\epsilon > 0$, we let $\delta = \min\{2, \frac{\epsilon}{8}\}$. If $0 < |x - 3| < \delta$, then $|x - 3| < 2 \Rightarrow -2 < x - 3 < 2 \Rightarrow 4 < x + 3 < 8 \Rightarrow |x + 3| < 8$. Also $|x - 3| < \frac{\epsilon}{8}$, so $|x^2 - 9| = |x + 3||x - 3| < 8 \cdot \frac{\epsilon}{8} = \epsilon$. Thus,
 $\lim_{x \rightarrow 3} x^2 = 9$.

34. From the figure, our choices for δ are $\delta_1 = 3 - \sqrt{9 - \epsilon}$ and $\delta_2 = \sqrt{9 + \epsilon} - 3$. The *largest* possible choice for δ is the minimum value of $\{\delta_1, \delta_2\}$; that is, $\delta = \min\{\delta_1, \delta_2\} = \delta_2 = \sqrt{9 + \epsilon} - 3$.

35. (a) The points of intersection in the graph are $(x_1, 2.6)$ and $(x_2, 3.4)$ with $x_1 \approx 0.891$ and $x_2 \approx 1.093$. Thus, we can take δ to be the smaller of $1 - x_1$ and $x_2 - 1$. So $\delta = x_2 - 1 \approx 0.093$.

(b) Solving $x^3 + x + 1 = 3 + \epsilon$ gives us two nonreal complex roots and one real root, which is

$$x(\epsilon) = \frac{(216 + 108\epsilon + 12\sqrt{336 + 324\epsilon + 81\epsilon^2})^{2/3} - 12}{6(216 + 108\epsilon + 12\sqrt{336 + 324\epsilon + 81\epsilon^2})^{1/3}}. \text{ Thus, } \delta = x(\epsilon) - 1.$$

(c) If $\epsilon = 0.4$, then $x(\epsilon) \approx 1.093272342$ and $\delta = x(\epsilon) - 1 \approx 0.093$, which agrees with our answer in part (a).

36. 1. *Guessing a value for δ* Let $\epsilon > 0$ be given. We have to find a number $\delta > 0$ such that $\left|\frac{1}{x} - \frac{1}{2}\right| < \epsilon$ whenever

$$0 < |x - 2| < \delta. \text{ But } \left|\frac{1}{x} - \frac{1}{2}\right| = \left|\frac{2 - x}{2x}\right| = \frac{|x - 2|}{|2x|} < \epsilon. \text{ We find a positive constant } C \text{ such that } \frac{1}{|2x|} < C \Rightarrow \frac{|x - 2|}{|2x|} < C|x - 2| \text{ and we can make } C|x - 2| < \epsilon \text{ by taking } |x - 2| < \frac{\epsilon}{C} = \delta. \text{ We restrict } x \text{ to lie in the}$$

interval $|x - 2| < 1 \Rightarrow 1 < x < 3$ so $1 > \frac{1}{x} > \frac{1}{3} \Rightarrow \frac{1}{6} < \frac{1}{2x} < \frac{1}{2} \Rightarrow \frac{1}{|2x|} < \frac{1}{2}$. So $C = \frac{1}{2}$ is suitable. Thus, we should choose $\delta = \min\{1, 2\epsilon\}$.

2. *Showing that δ works* Given $\epsilon > 0$ we let $\delta = \min\{1, 2\epsilon\}$. If $0 < |x - 2| < \delta$, then $|x - 2| < 1 \Rightarrow$

$$1 < x < 3 \Rightarrow \frac{1}{|2x|} < \frac{1}{2} \text{ (as in part 1). Also } |x - 2| < 2\epsilon, \text{ so } \left|\frac{1}{x} - \frac{1}{2}\right| = \frac{|x - 2|}{|2x|} < \frac{1}{2} \cdot 2\epsilon = \epsilon. \text{ This shows that } \lim_{x \rightarrow 2} (1/x) = \frac{1}{2}.$$

37. 1. Guessing a value for δ Given $\varepsilon > 0$, we must find $\delta > 0$ such that $|\sqrt{x} - \sqrt{a}| < \varepsilon$ whenever

$0 < |x - a| < \delta$. But $|\sqrt{x} - \sqrt{a}| = \frac{|x - a|}{\sqrt{x} + \sqrt{a}} < \varepsilon$ (from the hint). Now if we can find a positive constant C such that $\sqrt{x} + \sqrt{a} > C$ then $\frac{|x - a|}{\sqrt{x} + \sqrt{a}} < \frac{|x - a|}{C} < \varepsilon$, and we take $|x - a| < C\varepsilon$. We can find this number by restricting x to lie in some interval centered at a . If $|x - a| < \frac{1}{2}a$, then $-\frac{1}{2}a < x - a < \frac{1}{2}a \Rightarrow \frac{1}{2}a < x < \frac{3}{2}a \Rightarrow \sqrt{x} + \sqrt{a} > \sqrt{\frac{1}{2}a} + \sqrt{a}$, and so $C = \sqrt{\frac{1}{2}a} + \sqrt{a}$ is a suitable choice for the constant. So $|x - a| < \left(\sqrt{\frac{1}{2}a} + \sqrt{a}\right)\varepsilon$. This suggests that we let $\delta = \min\left\{\frac{1}{2}a, \left(\sqrt{\frac{1}{2}a} + \sqrt{a}\right)\varepsilon\right\}$.

2. Showing that δ works Given $\varepsilon > 0$, we let $\delta = \min\left\{\frac{1}{2}a, \left(\sqrt{\frac{1}{2}a} + \sqrt{a}\right)\varepsilon\right\}$. If $0 < |x - a| < \delta$, then $|x - a| < \frac{1}{2}a \Rightarrow \sqrt{x} + \sqrt{a} > \sqrt{\frac{1}{2}a} + \sqrt{a}$ (as in part 1). Also $|x - a| < \left(\sqrt{\frac{1}{2}a} + \sqrt{a}\right)\varepsilon$, so $|\sqrt{x} - \sqrt{a}| = \frac{|x - a|}{\sqrt{x} + \sqrt{a}} < \frac{\left(\sqrt{\frac{1}{2}a} + \sqrt{a}\right)\varepsilon}{\left(\sqrt{\frac{1}{2}a} + \sqrt{a}\right)} = \varepsilon$. Therefore, $\lim_{x \rightarrow a} \sqrt{x} = \sqrt{a}$ by the definition of a limit.

38. Suppose that $\lim_{t \rightarrow 0} H(t) = L$. Given $\varepsilon = \frac{1}{2}$, there exists $\delta > 0$ such that $0 < |t| < \delta \Rightarrow |H(t) - L| < \frac{1}{2} \Leftrightarrow L - \frac{1}{2} < H(t) < L + \frac{1}{2}$. For $0 < t < \delta$, $H(t) = 1$, so $1 < L + \frac{1}{2} \Rightarrow L > \frac{1}{2}$. For $-\delta < t < 0$, $H(t) = 0$, so $L - \frac{1}{2} < 0 \Rightarrow L < \frac{1}{2}$. This contradicts $L > \frac{1}{2}$. Therefore, $\lim_{t \rightarrow 0} H(t)$ does not exist.

39. Suppose that $\lim_{x \rightarrow 0} f(x) = L$. Given $\varepsilon = \frac{1}{2}$, there exists $\delta > 0$ such that $0 < |x| < \delta \Rightarrow |f(x) - L| < \frac{1}{2}$. Take any rational number r with $0 < |r| < \delta$. Then $f(r) = 0$, so $|0 - L| < \frac{1}{2}$, so $L \leq |L| < \frac{1}{2}$. Now take any irrational number s with $0 < |s| < \delta$. Then $f(s) = 1$, so $|1 - L| < \frac{1}{2}$. Hence, $1 - L < \frac{1}{2}$, so $L > \frac{1}{2}$. This contradicts $L < \frac{1}{2}$, so $\lim_{x \rightarrow 0} f(x)$ does not exist.

40. First suppose that $\lim_{x \rightarrow a} f(x) = L$. Then, given $\varepsilon > 0$ there exists $\delta > 0$ so that $0 < |x - a| < \delta \Rightarrow |f(x) - L| < \varepsilon$. Then $a - \delta < x < a \Rightarrow 0 < |x - a| < \delta$ so $|f(x) - L| < \varepsilon$. Thus, $\lim_{x \rightarrow a^-} f(x) = L$. Also $a < x < a + \delta \Rightarrow 0 < |x - a| < \delta$ so $|f(x) - L| < \varepsilon$. Hence, $\lim_{x \rightarrow a^+} f(x) = L$. Now suppose $\lim_{x \rightarrow a^-} f(x) = L = \lim_{x \rightarrow a^+} f(x)$. Let $\varepsilon > 0$ be given. Since $\lim_{x \rightarrow a^-} f(x) = L$, there exists $\delta_1 > 0$ so that $a - \delta_1 < x < a \Rightarrow |f(x) - L| < \varepsilon$. Since $\lim_{x \rightarrow a^+} f(x) = L$, there exists $\delta_2 > 0$ so that $a < x < a + \delta_2 \Rightarrow |f(x) - L| < \varepsilon$. Let δ be the smaller of δ_1 and δ_2 . Then $0 < |x - a| < \delta \Rightarrow a - \delta_1 < x < a$ or $a < x < a + \delta_2$ so $|f(x) - L| < \varepsilon$. Hence, $\lim_{x \rightarrow a} f(x) = L$. So we have proved that $\lim_{x \rightarrow a} f(x) = L \Leftrightarrow \lim_{x \rightarrow a^-} f(x) = L = \lim_{x \rightarrow a^+} f(x)$.

$$41. \frac{1}{(x+3)^4} > 10,000 \Leftrightarrow (x+3)^4 < \frac{1}{10,000} \Leftrightarrow |x+3| < \sqrt[4]{\frac{1}{10,000}} \Leftrightarrow |x - (-3)| < \frac{1}{10}$$

42. Given $M > 0$, we need $\delta > 0$ such that $0 < |x + 3| < \delta \Rightarrow 1/(x + 3)^4 > M$. Now $\frac{1}{(x + 3)^4} > M \Leftrightarrow$

$$(x + 3)^4 < \frac{1}{M} \Leftrightarrow |x + 3| < \sqrt[4]{\frac{1}{M}}. \text{ So take } \delta = \sqrt[4]{\frac{1}{M}}. \text{ Then } 0 < |x + 3| < \delta = \sqrt[4]{\frac{1}{M}} \Rightarrow$$

$$\frac{1}{(x + 3)^4} > M, \text{ so } \lim_{x \rightarrow -3} \frac{1}{(x + 3)^4} = \infty.$$

43. Let $N < 0$ be given. Then, for $x < -1$, we have $\frac{5}{(x + 1)^3} < N \Leftrightarrow \frac{5}{N} < (x + 1)^3 \Leftrightarrow \sqrt[3]{\frac{5}{N}} < x + 1$. Let

$$\delta = -\sqrt[3]{\frac{5}{N}}. \text{ Then } -1 - \delta < x < -1 \Rightarrow \sqrt[3]{\frac{5}{N}} < x + 1 < 0 \Rightarrow \frac{5}{(x + 1)^3} < N, \text{ so}$$

$$\lim_{x \rightarrow -1^-} \frac{5}{(x + 1)^3} = -\infty.$$

44. (a) Let M be given. Since $\lim_{x \rightarrow a} f(x) = \infty$, there exists $\delta_1 > 0$ such that $0 < |x - a| < \delta_1 \Rightarrow$

$$f(x) > M + 1 - c. \text{ Since } \lim_{x \rightarrow a} g(x) = c, \text{ there exists } \delta_2 > 0 \text{ such that } 0 < |x - a| < \delta_2 \Rightarrow |g(x) - c| < 1$$

$$\Rightarrow g(x) > c - 1. \text{ Let } \delta \text{ be the smaller of } \delta_1 \text{ and } \delta_2. \text{ Then } 0 < |x - a| < \delta \Rightarrow$$

$$f(x) + g(x) > (M + 1 - c) + (c - 1) = M. \text{ Thus, } \lim_{x \rightarrow a} [f(x) + g(x)] = \infty.$$

(b) Let $M > 0$ be given. Since $\lim_{x \rightarrow a} g(x) = c > 0$, there exists $\delta_1 > 0$ such that $0 < |x - a| < \delta_1 \Rightarrow$

$$|g(x) - c| < c/2 \Rightarrow g(x) > c/2. \text{ Since } \lim_{x \rightarrow a} f(x) = \infty, \text{ there exists } \delta_2 > 0 \text{ such that } 0 < |x - a| < \delta_2$$

$$\Rightarrow f(x) > 2M/c. \text{ Let } \delta = \min\{\delta_1, \delta_2\}. \text{ Then } 0 < |x - a| < \delta \Rightarrow f(x)g(x) > \frac{2M}{c} \cdot \frac{c}{2} = M, \text{ so}$$

$$\lim_{x \rightarrow a} f(x)g(x) = \infty.$$

(c) Let $N < 0$ be given. Since $\lim_{x \rightarrow a} g(x) = c < 0$, there exists $\delta_1 > 0$ such that $0 < |x - a| < \delta_1 \Rightarrow$

$$|g(x) - c| < -c/2 \Rightarrow g(x) < c/2. \text{ Since } \lim_{x \rightarrow a} f(x) = \infty, \text{ there exists } \delta_2 > 0 \text{ such that } 0 < |x - a| < \delta_2$$

$$\Rightarrow f(x) > 2N/c. \text{ (Note that } c < 0 \text{ and } N < 0 \Rightarrow 2N/c > 0.) \text{ Let } \delta = \min\{\delta_1, \delta_2\}. \text{ Then}$$

$$0 < |x - a| < \delta \Rightarrow f(x) > 2N/c \Rightarrow f(x)g(x) < \frac{2N}{c} \cdot \frac{c}{2} = N, \text{ so } \lim_{x \rightarrow a} f(x)g(x) = -\infty.$$

2.5 Continuity

1. From Definition 1, $\lim_{x \rightarrow 4} f(x) = f(4)$.

2. The graph of f has no hole, jump, or vertical asymptote.

3. (a) The following are the numbers at which f is discontinuous and the type of discontinuity at that number:
 -4 (removable), -2 (jump), 2 (jump), 4 (infinite).

(b) f is continuous from the left at -2 since $\lim_{x \rightarrow -2^-} f(x) = f(-2)$. f is continuous from the right at 2 and 4 since

$$\lim_{x \rightarrow 2^+} f(x) = f(2) \text{ and } \lim_{x \rightarrow 4^+} f(x) = f(4). \text{ It is continuous from neither side at } -4 \text{ since } f(-4) \text{ is undefined.}$$

4. g is continuous on $[-4, -2)$, $(-2, 2)$, $[2, 4)$, $(4, 6)$, and $(6, 8)$.

5. The graph of $y = f(x)$ must have a discontinuity at $x = 3$ and must show that $\lim_{x \rightarrow 3^-} f(x) = f(3)$.

6.

7. (a)

- (b) There are discontinuities at times $t = 1, 2, 3$, and 4 . A person parking in the lot would want to keep in mind that the charge will jump at the beginning of each hour.

8. (a) Continuous; at the location in question, the temperature changes smoothly as time passes, without any instantaneous jumps from one temperature to another.
 (b) Continuous; the temperature at a specific time changes smoothly as the distance due west from New York City increases, without any instantaneous jumps.
 (c) Discontinuous; as the distance due west from New York City increases, the altitude above sea level may jump from one height to another without going through all of the intermediate values—at a cliff, for example.
 (d) Discontinuous; as the distance traveled increases, the cost of the ride jumps in small increments.
 (e) Discontinuous; when the lights are switched on (or off), the current suddenly changes between 0 and some nonzero value, without passing through all of the intermediate values. This is debatable, though, depending on your definition of current.
9. Since f and g are continuous functions,

$$\begin{aligned}\lim_{x \rightarrow 3} [2f(x) - g(x)] &= 2 \lim_{x \rightarrow 3} f(x) - \lim_{x \rightarrow 3} g(x) && \text{[by Limit Laws 2 and 3]} \\ &= 2f(3) - g(3) && \text{[by continuity of } f \text{ and } g \text{ at } x = 3\text{]} \\ &= 2 \cdot 5 - g(3) = 10 - g(3)\end{aligned}$$

Since it is given that $\lim_{x \rightarrow 3} [2f(x) - g(x)] = 4$, we have $10 - g(3) = 4$, so $g(3) = 6$.

10. $\lim_{x \rightarrow 4} f(x) = \lim_{x \rightarrow 4} (x^2 + \sqrt{7-x}) = \lim_{x \rightarrow 4} x^2 + \sqrt{\lim_{x \rightarrow 4} 7 - \lim_{x \rightarrow 4} x} = 4^2 + \sqrt{7-4} = 16 + \sqrt{3} = f(4).$

By the definition of continuity, f is continuous at $a = 4$.

11. $\lim_{x \rightarrow -1} f(x) = \lim_{x \rightarrow -1} (x + 2x^3)^4 = \left(\lim_{x \rightarrow -1} x + 2 \lim_{x \rightarrow -1} x^3 \right)^4 = [-1 + 2(-1)^3]^4 = (-3)^4 = 81 = f(-1).$

By the definition of continuity, f is continuous at $a = -1$.

12. $\lim_{x \rightarrow 4} g(x) = \lim_{x \rightarrow 4} \frac{x+1}{2x^2-1} = \frac{\lim_{x \rightarrow 4} x + \lim_{x \rightarrow 4} 1}{2 \lim_{x \rightarrow 4} x^2 - \lim_{x \rightarrow 4} 1} = \frac{4+1}{2(4)^2-1} = \frac{5}{31} = g(4).$ So g is continuous at 4.

$$13. \text{ For } a > 2, \text{ we have } \lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} \frac{2x+3}{x-2} = \frac{\lim_{x \rightarrow a} (2x+3)}{\lim_{x \rightarrow a} (x-2)} \quad [\text{Limit Law 5}] = \frac{2 \lim_{x \rightarrow a} x + \lim_{x \rightarrow a} 3}{\lim_{x \rightarrow a} x - \lim_{x \rightarrow a} 2}$$

$[1, 2, \text{ and } 3] = \frac{2a+3}{a-2}$ [7 and 8] $= f(a)$. Thus, f is continuous at $x = a$ for every a in $(2, \infty)$; that is, f is continuous on $(2, \infty)$.

$$14. \text{ For } a < 3, \text{ we have } \lim_{x \rightarrow a} g(x) = \lim_{x \rightarrow a} 2\sqrt{3-x} = 2 \lim_{x \rightarrow a} \sqrt{3-x} \quad [\text{Limit Law 3}] = 2\sqrt{\lim_{x \rightarrow a} (3-x)} \quad [11]$$

$$= 2\sqrt{\lim_{x \rightarrow a} 3 - \lim_{x \rightarrow a} x} \quad [2] = 2\sqrt{3-a} \quad [7 \text{ and } 8] = g(a), \text{ so } g \text{ is continuous at } x = a \text{ for every } a \text{ in } (-\infty, 3).$$

Also, $\lim_{x \rightarrow 3^-} g(x) = 0 = g(3)$, so g is continuous from the left at 3. Thus, g is continuous on $(-\infty, 3]$.

$$15. f(x) = -\frac{1}{(x-1)^2} \text{ is discontinuous at 1 since } f(1) \text{ is not defined.}$$

$$16. f(x) = \begin{cases} 1/(x-1) & \text{if } x \neq 1 \\ 2 & \text{if } x = 1 \end{cases} \text{ is discontinuous at 1 because}$$

$\lim_{x \rightarrow 1} f(x)$ does not exist.

$$17. f(x) = \begin{cases} 1-x^2 & \text{if } x < 1 \\ 1/x & \text{if } x \geq 1 \end{cases}$$

The left-hand limit of f at $a = 1$ is

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (1-x^2) = 0. \text{ The right-hand limit of } f \text{ at } a = 1$$

is $\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (1/x) = 1$. Since these limits are not equal,

$\lim_{x \rightarrow 1} f(x)$ does not exist and f is discontinuous at 1.

$$18. f(x) = \begin{cases} \frac{x^2-x}{x^2-1} & \text{if } x \neq 1 \\ 1 & \text{if } x = 1 \end{cases}$$

$$\lim_{x \rightarrow 1} f(x) = \lim_{x \rightarrow 1} \frac{x^2-x}{x^2-1} = \lim_{x \rightarrow 1} \frac{x(x-1)}{(x+1)(x-1)}$$

$$= \lim_{x \rightarrow 1} \frac{x}{x+1} = \frac{1}{2},$$

but $f(1) = 1$, so f is discontinuous at 1.

$$19. f(x) = \begin{cases} \frac{x^2 - x - 12}{x + 3} & \text{if } x \neq -3 \\ -5 & \text{if } x = -3 \end{cases} = \begin{cases} x - 4 & \text{if } x \neq -3 \\ -5 & \text{if } x = -3 \end{cases}$$

So $\lim_{x \rightarrow -3} f(x) = \lim_{x \rightarrow -3} (x - 4) = -7$ and $f(-3) = -5$.

Since $\lim_{x \rightarrow -3} f(x) \neq f(-3)$, f is discontinuous at -3 .

$$20. f(x) = \begin{cases} 1 + x^2 & \text{if } x < 1 \\ 4 - x & \text{if } x \geq 1 \end{cases}$$

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (1 + x^2) = 1 + 1^2 = 2 \text{ and}$$

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (4 - x) = 4 - 1 = 3.$$

Thus, f is discontinuous at 1 because $\lim_{x \rightarrow 1} f(x)$ does not exist.

21. $F(x) = \frac{x}{x^2 + 5x + 6}$ is a rational function. So by Theorem 5 (or Theorem 7), F is continuous at every number in its domain, $\{x \mid x^2 + 5x + 6 \neq 0\} = \{x \mid (x + 3)(x + 2) \neq 0\} = \{x \mid x \neq -3, -2\}$ or $(-\infty, -3) \cup (-3, -2) \cup (-2, \infty)$.

22. By Theorem 7, the root function $\sqrt[3]{x}$ and the polynomial function $1 + x^3$ are continuous on $\mathbb{R}$. By part 4 of Theorem 4, the product $G(x) = \sqrt[3]{x}(1 + x^3)$ is continuous on its domain, $\mathbb{R}$.

23. By Theorem 5, the polynomials x^2 and $2x - 1$ are continuous on $(-\infty, \infty)$. By Theorem 7, the root function $\sqrt{x}$ is continuous on $[0, \infty)$. By Theorem 9, the composite function $\sqrt{2x - 1}$ is continuous on its domain, $[\frac{1}{2}, \infty)$. By part 1 of Theorem 4, the sum $R(x) = x^2 + \sqrt{2x - 1}$ is continuous on $[\frac{1}{2}, \infty)$.

24. By Theorem 7, the trigonometric function $\sin x$ and the polynomial function $x + 1$ are continuous on $\mathbb{R}$. By part 5 of Theorem 4, $h(x) = \frac{\sin x}{x + 1}$ is continuous on its domain, $\{x \mid x \neq -1\}$.

25. By Theorem 5, the polynomial $1 - x^2$ is continuous on $(-\infty, \infty)$. By Theorem 7, $\cos$ is continuous on its domain, $\mathbb{R}$. By Theorem 9, $\cos(1 - x^2)$ is continuous on its domain, which is $\mathbb{R}$.

26. By Theorem 5, the polynomial $2x$ is continuous on $(-\infty, \infty)$. By Theorem 7, $\tan$ is continuous at every number in its domain; that is, $\{x \mid x \neq \frac{\pi}{2} + \pi n\}$. By Theorem 9, $\tan 2x$ is continuous on its domain, which is $\{x \mid 2x \neq \frac{\pi}{2} + \pi n\} = \{x \mid x \neq \frac{\pi}{4} + \frac{\pi}{2}n\}$ (the odd multiples of $\frac{\pi}{4}$).

27. By Theorem 7, the root function $\sqrt{x}$ and the trigonometric function $\sin x$ are continuous on their domains, $[0, \infty)$ and $(-\infty, \infty)$, respectively. Thus, the product $F(x) = \sqrt{x} \sin x$ is continuous on the intersection of those domains, $[0, \infty)$, by part 4 of Theorem 4.

28. The sine and cosine functions are continuous everywhere by Theorem 7, so $F(x) = \sin(\cos(\sin x))$, which is the composite of sine, cosine, and (once again) sine, is continuous everywhere by Theorem 9.

29.

$y = \frac{1}{1 + \sin x}$ is undefined and hence discontinuous when $1 + \sin x = 0 \Leftrightarrow \sin x = -1 \Leftrightarrow x = -\frac{\pi}{2} + 2\pi n$, n an integer. The figure shows discontinuities for $n = -1, 0$, and 1 ; that is, $-\frac{5\pi}{2} \approx -7.85$, $-\frac{\pi}{2} \approx -1.57$, and $\frac{3\pi}{2} \approx 4.71$.

30.

The function $y = f(x) = \tan \sqrt{x}$ is continuous throughout its domain because it is the composite of a trigonometric function and a root function. The square root function has domain $[0, \infty)$ and the tangent function has domain $\{x \mid x \neq \frac{\pi}{2} + \pi n\}$. So f is discontinuous when $x < 0$ and when $\sqrt{x} = \frac{\pi}{2} + \pi n \Rightarrow x = (\frac{\pi}{2} + \pi n)^2$, where n is a nonnegative integer. Note that as x increases, the distance between discontinuities increases.

31. Because we are dealing with root functions, $5 + \sqrt{x}$ is continuous on $[0, \infty)$, $\sqrt{x+5}$ is continuous on $[-5, \infty)$, so the quotient $f(x) = \frac{5 + \sqrt{x}}{\sqrt{5+x}}$ is continuous on $[0, \infty)$. Since f is continuous at $x = 4$, $\lim_{x \rightarrow 4} f(x) = f(4) = \frac{7}{3}$.

32. Because x is continuous on $\mathbb{R}$, $\sin x$ is continuous on $\mathbb{R}$, and $x + \sin x$ is continuous on $\mathbb{R}$, the composite function $f(x) = \sin(x + \sin x)$ is continuous on $\mathbb{R}$, so $\lim_{x \rightarrow \pi} f(x) = f(\pi) = \sin(\pi + \sin \pi) = \sin \pi = 0$.

$$33. f(x) = \begin{cases} x^2 & \text{if } x < 1 \\ \sqrt{x} & \text{if } x \geq 1 \end{cases}$$

By Theorem 5, since $f(x)$ equals the polynomial x^2 on $(-\infty, 1)$, f is continuous on $(-\infty, 1)$. By Theorem 7, since $f(x)$ equals the root function $\sqrt{x}$ on $(1, \infty)$, f is continuous on $(1, \infty)$. At $x = 1$,

$$\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} x^2 = 1 \text{ and } \lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} \sqrt{x} = 1. \text{ Thus, } \lim_{x \rightarrow 1} f(x) \text{ exists and equals } 1. \text{ Also,}$$

$$f(1) = \sqrt{1} = 1. \text{ Thus, } f \text{ is continuous at } x = 1. \text{ We conclude that } f \text{ is continuous on } (-\infty, \infty).$$

$$34. f(x) = \begin{cases} \sin x & \text{if } x < \pi/4 \\ \cos x & \text{if } x \geq \pi/4 \end{cases}$$

By Theorem 7, the trigonometric functions are continuous. Since $f(x) = \sin x$ on $(-\infty, \pi/4)$ and $f(x) = \cos x$ on $(\pi/4, \infty)$, f is continuous on $(-\infty, \pi/4) \cup (\pi/4, \infty)$. $\lim_{x \rightarrow (\pi/4)^-} f(x) = \lim_{x \rightarrow (\pi/4)^-} \sin x = \sin \frac{\pi}{4} = 1/\sqrt{2}$ since

the sine function is continuous at $\pi/4$. Similarly, $\lim_{x \rightarrow (\pi/4)^+} f(x) = \lim_{x \rightarrow (\pi/4)^+} \cos x = 1/\sqrt{2}$ by continuity of the

cosine function at $\pi/4$. Thus, $\lim_{x \rightarrow (\pi/4)} f(x)$ exists and equals $1/\sqrt{2}$, which agrees with the value $f(\pi/4)$.

Therefore, f is continuous at $\pi/4$, so f is continuous on $(-\infty, \infty)$.

$$35. f(x) = \begin{cases} 1 + x^2 & \text{if } x \leq 0 \\ 2 - x & \text{if } 0 < x \leq 2 \\ (x - 2)^2 & \text{if } x > 2 \end{cases}$$

f is continuous on $(-\infty, 0)$, $(0, 2)$, and $(2, \infty)$ since it is a polynomial on

each of these intervals. Now $\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} (1 + x^2) = 1$ and

$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} (2 - x) = 2$, so f is discontinuous at 0. Since $f(0) = 1$, f is continuous from the left at 0.

Also, $\lim_{x \rightarrow 2^-} f(x) = \lim_{x \rightarrow 2^-} (2 - x) = 0$, $\lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} (x - 2)^2 = 0$, and $f(2) = 0$, so f is continuous at 2.

The only number at which f is discontinuous is 0.

$$36. f(x) = \begin{cases} x + 1 & \text{if } x \leq 1 \\ 1/x & \text{if } 1 < x < 3 \\ \sqrt{x - 3} & \text{if } x \geq 3 \end{cases}$$

f is continuous on $(-\infty, 1)$, $(1, 3)$, and $(3, \infty)$, where it is a polynomial, a rational function, and a composite of a root function with a polynomial, respectively. Now $\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (x + 1) = 2$ and

$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (1/x) = 1$, so f is discontinuous at 1.

Since $f(1) = 2$, f is continuous from the left at 1. Also, $\lim_{x \rightarrow 3^-} f(x) = \lim_{x \rightarrow 3^-} (1/x) = 1/3$, and

$\lim_{x \rightarrow 3^+} f(x) = \lim_{x \rightarrow 3^+} \sqrt{x - 3} = 0 = f(3)$, so f is discontinuous at 3, but it is continuous from the right at 3.

$$37. f(x) = \begin{cases} x + 2 & \text{if } x < 0 \\ 2x^2 & \text{if } 0 \leq x \leq 1 \\ 2 - x & \text{if } x > 1 \end{cases}$$

f is continuous on $(-\infty, 0)$, $(0, 1)$, and $(1, \infty)$ since on each of these intervals it is a polynomial. Now $\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} (x + 2) = 2$ and

$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} 2x^2 = 0$, so f is discontinuous at 0. Since $f(0) = 0$, f

is continuous from the right at 0. Also $\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} 2x^2 = 2$ and

$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} (2 - x) = 1$, so f is discontinuous at 1. Since

$f(1) = 2$, f is continuous from the left at 1.

38. By Theorem 5, each piece of F is continuous on its domain. We need to check for continuity at $r = R$.

$\lim_{r \rightarrow R^-} F(r) = \lim_{r \rightarrow R^-} \frac{GMr}{R^3} = \frac{GM}{R^2}$ and $\lim_{r \rightarrow R^+} F(r) = \lim_{r \rightarrow R^+} \frac{GM}{r^2} = \frac{GM}{R^2}$, so $\lim_{r \rightarrow R} F(r) = \frac{GM}{R^2}$. Since $F(R) = \frac{GM}{R^2}$, F is continuous at R . Therefore, F is a continuous function of r .

39. f is continuous on $(-\infty, 3)$ and $(3, \infty)$. Now $\lim_{x \rightarrow 3^-} f(x) = \lim_{x \rightarrow 3^-} (cx + 1) = 3c + 1$ and

$\lim_{x \rightarrow 3^+} f(x) = \lim_{x \rightarrow 3^+} (cx^2 - 1) = 9c - 1$. So f is continuous $\Leftrightarrow 3c + 1 = 9c - 1 \Leftrightarrow 6c = 2 \Leftrightarrow c = \frac{1}{3}$.

Thus, for f to be continuous on $(-\infty, \infty)$, $c = \frac{1}{3}$.

40. The functions $x^2 - c^2$ and $cx + 20$, considered on the intervals $(-\infty, 4)$ and $[4, \infty)$ respectively, are continuous for any value of c . So the only possible discontinuity is at $x = 4$. For the function to be continuous at $x = 4$, the left-hand and right-hand limits must be the same. Now $\lim_{x \rightarrow 4^-} g(x) = \lim_{x \rightarrow 4^-} (x^2 - c^2) = 16 - c^2$ and

$$\lim_{x \rightarrow 4^+} g(x) = \lim_{x \rightarrow 4^+} (cx + 20) = 4c + 20 = g(4). \text{ Thus, } 16 - c^2 = 4c + 20 \Leftrightarrow c^2 + 4c + 4 = 0 \Leftrightarrow c = -2.$$

41. (a) $f(x) = \frac{x^2 - 2x - 8}{x + 2} = \frac{(x - 4)(x + 2)}{x + 2}$ has a removable discontinuity at -2 because $g(x) = x - 4$ is continuous on $\mathbb{R}$ and $f(x) = g(x)$ for $x \neq -2$. [The discontinuity is removed by defining $f(-2) = -6$.]

(b) $f(x) = \frac{x - 7}{|x - 7|} \Rightarrow \lim_{x \rightarrow 7^-} f(x) = -1$ and $\lim_{x \rightarrow 7^+} f(x) = 1$. Thus, $\lim_{x \rightarrow 7} f(x)$ does not exist, so the discontinuity is not removable. (It is a jump discontinuity.)

(c) $f(x) = \frac{x^3 + 64}{x + 4} = \frac{(x + 4)(x^2 - 4x + 16)}{x + 4}$ has a removable discontinuity at -4 because $g(x) = x^2 - 4x + 16$ is continuous on $\mathbb{R}$ and $f(x) = g(x)$ for $x \neq -4$. [The discontinuity is removed by defining $f(-4) = 48$.]

(d) $f(x) = \frac{3 - \sqrt{x}}{9 - x} = \frac{3 - \sqrt{x}}{(3 - \sqrt{x})(3 + \sqrt{x})}$ has a removable discontinuity at 9 because $g(x) = \frac{1}{3 + \sqrt{x}}$ is continuous on $\mathbb{R}$ and $f(x) = g(x)$ for $x \neq 9$. [The discontinuity is removed by defining $f(9) = \frac{1}{6}$.]

42.

f does not satisfy the conclusion of the Intermediate Value Theorem.

f does satisfy the conclusion of the Intermediate Value Theorem.

43. $f(x) = x^3 - x^2 + x$ is continuous on the interval $[2, 3]$, $f(2) = 6$, and $f(3) = 21$. Since $6 < 10 < 21$, there is a number c in $(2, 3)$ such that $f(c) = 10$ by the Intermediate Value Theorem.
44. $f(x) = x^2$ is continuous on the interval $[1, 2]$, $f(1) = 1$, and $f(2) = 4$. Since $1 < 2 < 4$, there is a number c in $(1, 2)$ such that $f(c) = c^2 = 2$ by the Intermediate Value Theorem.
45. $f(x) = x^4 + x - 3$ is continuous on the interval $[1, 2]$, $f(1) = -1$, and $f(2) = 15$. Since $-1 < 0 < 15$, there is a number c in $(1, 2)$ such that $f(c) = 0$ by the Intermediate Value Theorem. Thus, there is a root of the equation $x^4 + x - 3 = 0$ in the interval $(1, 2)$.
46. $f(x) = \sqrt[3]{x} + x - 1$ is continuous on the interval $[0, 1]$, $f(0) = -1$, and $f(1) = 1$. Since $-1 < 0 < 1$, there is a number c in $(0, 1)$ such that $f(c) = 0$ by the Intermediate Value Theorem. Thus, there is a root of the equation $\sqrt[3]{x} + x - 1 = 0$, or $\sqrt[3]{x} = 1 - x$, in the interval $(0, 1)$.
47. $f(x) = \cos x - x$ is continuous on the interval $[0, 1]$, $f(0) = 1$, and $f(1) = \cos 1 - 1 \approx -0.46$. Since $-0.46 < 0 < 1$, there is a number c in $(0, 1)$ such that $f(c) = 0$ by the Intermediate Value Theorem. Thus, there is a root of the equation $\cos x - x = 0$, or $\cos x = x$, in the interval $(0, 1)$.

48. $f(x) = \tan x - 2x$ is continuous on the interval $[0, 1.4]$, $f(1) = \tan 1 - 2 \approx -0.44$, and $f(1.4) = \tan 1.4 - 2.8 \approx 3.00$. Since $-0.44 < 0 < 3.00$, there is a number c in $(0, 1.4)$ such that $f(c) = 0$ by the Intermediate Value Theorem. Thus, there is a root of the equation $\tan x - 2x = 0$, or $\tan x = 2x$, in the interval $(0, 1.4)$.
49. (a) $f(x) = \sin x - 2 + x$ is continuous on $[0, 2]$, $f(0) = -2$, and $f(2) = \sin 2 \approx 0.91$. Since $-2 < 0 < 0.91$, there is a number c in $(0, 2)$ such that $f(c) = 0$ by the Intermediate Value Theorem. Thus, there is a root of the equation $\sin x - 2 + x = 0$, or $\sin x = 2 - x$, in the interval $(0, 2)$.
- (b) $f(1.10) \approx -0.009 < 0$ and $f(1.11) \approx 0.006 > 0$, so there is a root between 1.10 and 1.11.
50. (a) $f(x) = x^5 - x^2 + 2x + 3$ is continuous on $[-1, 0]$, $f(-1) = -1 < 0$, and $f(0) = 3 > 0$. Since $-1 < 0 < 3$, there is a number c in $(-1, 0)$ such that $f(c) = 0$ by the Intermediate Value Theorem. Thus, there is a root of the equation $x^5 - x^2 + 2x + 3 = 0$ in the interval $(-1, 0)$.
- (b) $f(-0.88) \approx -0.062 < 0$ and $f(-0.87) \approx 0.0047 > 0$, so there is a root between -0.88 and -0.87 .
51. (a) Let $f(x) = x^5 - x^2 - 4$. Then $f(1) = 1^5 - 1^2 - 4 = -4 < 0$ and $f(2) = 2^5 - 2^2 - 4 = 24 > 0$. So by the Intermediate Value Theorem, there is a number c in $(1, 2)$ such that $f(c) = c^5 - c^2 - 4 = 0$.
- (b) We can see from the graphs that, correct to three decimal places, the root is $x \approx 1.434$.

52. (a) Let $f(x) = \sqrt{x-5} - \frac{1}{x+3}$. Then $f(5) = -\frac{1}{8} < 0$ and $f(6) = \frac{8}{9} > 0$, and f is continuous on $[5, \infty)$. So by the Intermediate Value Theorem, there is a number c in $(5, 6)$ such that $f(c) = 0$. This implies that $\frac{1}{c+3} = \sqrt{c-5}$.

- (b) Using the intersect feature of the graphing device, we find that the root of the equation is $x = 5.016$, correct to three decimal places.

53. $(\Rightarrow)$ If f is continuous at a , then by Theorem 8 with $g(h) = a + h$, we have

$$\lim_{h \rightarrow 0} f(a+h) = f\left(\lim_{h \rightarrow 0} (a+h)\right) = f(a).$$

- $(\Leftarrow)$ Let $\varepsilon > 0$. Since $\lim_{h \rightarrow 0} f(a+h) = f(a)$, there exists $\delta > 0$ such that $0 < |h| < \delta \Rightarrow$

$$|f(a+h) - f(a)| < \varepsilon. \text{ So if } 0 < |x - a| < \delta, \text{ then } |f(x) - f(a)| = |f(a + (x - a)) - f(a)| < \varepsilon.$$

Thus, $\lim_{x \rightarrow a} f(x) = f(a)$ and so f is continuous at a .

$$\begin{aligned}
 54. \lim_{h \rightarrow 0} \sin(a+h) &= \lim_{h \rightarrow 0} (\sin a \cos h + \cos a \sin h) = \lim_{h \rightarrow 0} (\sin a \cos h) + \lim_{h \rightarrow 0} (\cos a \sin h) \\
 &= \left(\lim_{h \rightarrow 0} \sin a \right) \left(\lim_{h \rightarrow 0} \cos h \right) + \left(\lim_{h \rightarrow 0} \cos a \right) \left(\lim_{h \rightarrow 0} \sin h \right) \\
 &= (\sin a)(1) + (\cos a)(0) = \sin a
 \end{aligned}$$

55. As in the previous exercise, we must show that $\lim_{h \rightarrow 0} \cos(a+h) = \cos a$ to prove that the cosine function is continuous.

$$\begin{aligned}
 \lim_{h \rightarrow 0} \cos(a+h) &= \lim_{h \rightarrow 0} (\cos a \cos h - \sin a \sin h) \\
 &= \lim_{h \rightarrow 0} (\cos a \cos h) - \lim_{h \rightarrow 0} (\sin a \sin h) \\
 &= \left(\lim_{h \rightarrow 0} \cos a \right) \left(\lim_{h \rightarrow 0} \cos h \right) - \left(\lim_{h \rightarrow 0} \sin a \right) \left(\lim_{h \rightarrow 0} \sin h \right) \\
 &= (\cos a)(1) - (\sin a)(0) = \cos a
 \end{aligned}$$

56. (a) Since f is continuous at a , $\lim_{x \rightarrow a} f(x) = f(a)$. Thus, using the Constant Multiple Law of Limits, we have

$$\lim_{x \rightarrow a} (cf)(x) = \lim_{x \rightarrow a} cf(x) = c \lim_{x \rightarrow a} f(x) = cf(a) = (cf)(a). \text{ Therefore, } cf \text{ is continuous at } a.$$

- (b) Since f and g are continuous at a , $\lim_{x \rightarrow a} f(x) = f(a)$ and $\lim_{x \rightarrow a} g(x) = g(a)$. Since $g(a) \neq 0$, we can use the

$$\text{Quotient Law of Limits: } \lim_{x \rightarrow a} \left(\frac{f}{g} \right)(x) = \lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \frac{\lim_{x \rightarrow a} f(x)}{\lim_{x \rightarrow a} g(x)} = \frac{f(a)}{g(a)} = \left(\frac{f}{g} \right)(a). \text{ Thus, } \frac{f}{g} \text{ is continuous}$$

at a .

57. $f(x) = \begin{cases} 0 & \text{if } x \text{ is rational} \\ 1 & \text{if } x \text{ is irrational} \end{cases}$ is continuous nowhere. For, given any number a and any $\delta > 0$, the interval

$(a - \delta, a + \delta)$ contains both infinitely many rational and infinitely many irrational numbers. Since $f(a) = 0$ or 1 , there are infinitely many numbers x with $0 < |x - a| < \delta$ and $|f(x) - f(a)| = 1$. Thus, $\lim_{x \rightarrow a} f(x) \neq f(a)$.

[In fact, $\lim_{x \rightarrow a} f(x)$ does not even exist.]

58. $g(x) = \begin{cases} 0 & \text{if } x \text{ is rational} \\ x & \text{if } x \text{ is irrational} \end{cases}$ is continuous at 0 . To see why, note that $-|x| \leq g(x) \leq |x|$, so by the Squeeze

Theorem $\lim_{x \rightarrow 0} g(x) = 0 = g(0)$. But g is continuous nowhere else. For if $a \neq 0$ and $\delta > 0$, the interval

$(a - \delta, a + \delta)$ contains both infinitely many rational and infinitely many irrational numbers. Since $g(a) = 0$ or a , there are infinitely many numbers x with $0 < |x - a| < \delta$ and $|g(x) - g(a)| > |a|/2$. Thus, $\lim_{x \rightarrow a} g(x) \neq g(a)$.

59. If there is such a number, it satisfies the equation $x^3 + 1 = x \Leftrightarrow x^3 - x + 1 = 0$. Let the left-hand side of this equation be called $f(x)$. Now $f(-2) = -5 < 0$, and $f(-1) = 1 > 0$. Note also that $f(x)$ is a polynomial, and thus continuous. So by the Intermediate Value Theorem, there is a number c between -2 and -1 such that $f(c) = 0$, so that $c = c^3 + 1$.

60. (a) $\lim_{x \rightarrow 0^+} F(x) = 0$ and $\lim_{x \rightarrow 0^-} F(x) = 0$, so $\lim_{x \rightarrow 0} F(x) = 0$, which is $F(0)$, and hence F is continuous at $x = a$ if $a = 0$. For $a > 0$, $\lim_{x \rightarrow a} F(x) = \lim_{x \rightarrow a} x = a = F(a)$. For $a < 0$, $\lim_{x \rightarrow a} F(x) = \lim_{x \rightarrow a} (-x) = -a = F(a)$. Thus, F is continuous at $x = a$; that is, continuous everywhere.

(b) Assume that f is continuous on the interval I . Then for $a \in I$, $\lim_{x \rightarrow a} |f(x)| = \left| \lim_{x \rightarrow a} f(x) \right| = |f(a)|$ by Theorem 8. (If a is an endpoint of I , use the appropriate one-sided limit.) So $|f|$ is continuous on I .

(c) No, the converse is false. For example, the function $f(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ -1 & \text{if } x < 0 \end{cases}$ is not continuous at $x = 0$, but $|f(x)| = 1$ is continuous on $\mathbb{R}$.

61. Define $u(t)$ to be the monk's distance from the monastery, as a function of time, on the first day, and define $d(t)$ to be his distance from the monastery, as a function of time, on the second day. Let D be the distance from the monastery to the top of the mountain. From the given information we know that $u(0) = 0$, $u(12) = D$, $d(0) = D$ and $d(12) = 0$. Now consider the function $u - d$, which is clearly continuous. We calculate that $(u - d)(0) = -D$ and $(u - d)(12) = D$. So by the Intermediate Value Theorem, there must be some time t_0 between 0 and 12 such that $(u - d)(t_0) = 0 \Leftrightarrow u(t_0) = d(t_0)$. So at time t_0 after 7:00 A.M., the monk will be at the same place on both days.

2.6 Tangents, Velocities, and Other Rates of Change

1. (a) This is just the slope of the line through two points: $m_{PQ} = \frac{\Delta y}{\Delta x} = \frac{f(x) - f(3)}{x - 3}$.

(b) This is the limit of the slope of the secant line PQ as Q approaches P : $m = \lim_{x \rightarrow 3} \frac{f(x) - f(3)}{x - 3}$.

2. (a) Average velocity = $\frac{\Delta s}{\Delta t} = \frac{f(a+h) - f(a)}{(a+h) - a} = \frac{f(a+h) - f(a)}{h}$

(b) Instantaneous velocity = $\lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h}$

3. The slope at D is the largest positive slope, followed by the positive slope at E . The slope at C is zero. The slope at B is steeper than at A (both are negative). In decreasing order, we have the slopes at: D, E, C, A , and B .

4. The curve looks more like a line as the viewing rectangle gets smaller.

5. (a) (i) Using Definition 1,

$$\begin{aligned}
 m &= \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} = \lim_{x \rightarrow -3} \frac{f(x) - f(-3)}{x - (-3)} = \lim_{x \rightarrow -3} \frac{(x^2 + 2x) - (3)}{x - (-3)} = \lim_{x \rightarrow -3} \frac{(x+3)(x-1)}{x+3} \\
 &= \lim_{x \rightarrow -3} (x-1) = -4
 \end{aligned}$$

- (ii) Using Equation 2,

$$\begin{aligned}
 m &= \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{h \rightarrow 0} \frac{f(-3+h) - f(-3)}{h} = \lim_{h \rightarrow 0} \frac{[(-3+h)^2 + 2(-3+h)] - (3)}{h} \\
 &= \lim_{h \rightarrow 0} \frac{9 - 6h + h^2 - 6 + 2h - 3}{h} = \lim_{h \rightarrow 0} \frac{h(h-4)}{h} = \lim_{h \rightarrow 0} (h-4) = -4
 \end{aligned}$$

- (b) Using the point-slope form of the equation of a line, an equation of the tangent line is
- $y - 3 = -4(x + 3)$
- .

Solving for y gives us $y = -4x - 9$, which is the slope-intercept form of the equation of the tangent line.

- (c)

$$\begin{aligned}
 6. (a) (i) m &= \lim_{x \rightarrow -1} \frac{f(x) - f(-1)}{x - (-1)} = \lim_{x \rightarrow -1} \frac{x^3 - (-1)}{x + 1} = \lim_{x \rightarrow -1} \frac{(x+1)(x^2 - x + 1)}{x + 1} \\
 &= \lim_{x \rightarrow -1} (x^2 - x + 1) = 3
 \end{aligned}$$

$$\begin{aligned}
 (ii) m &= \lim_{h \rightarrow 0} \frac{f(-1+h) - f(-1)}{h} = \lim_{h \rightarrow 0} \frac{(-1+h)^3 - (-1)}{h} = \lim_{h \rightarrow 0} \frac{h^3 - 3h^2 + 3h - 1 + 1}{h} \\
 &= \lim_{h \rightarrow 0} (h^2 - 3h + 3) = 3
 \end{aligned}$$

$$(b) y - (-1) = 3[x - (-1)] \Leftrightarrow y + 1 = 3x + 3 \Leftrightarrow y = 3x + 2$$

- (c)

7. Using (2) with
- $f(x) = 1 + 2x - x^3$
- and
- $P(1, 2)$
- ,

$$\begin{aligned}
 m &= \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{h \rightarrow 0} \frac{f(1+h) - f(1)}{h} = \lim_{h \rightarrow 0} \frac{[1 + 2(1+h) - (1+h)^3] - 2}{h} \\
 &= \lim_{h \rightarrow 0} \frac{1 + 2 + 2h - (1 + 3h + 3h^2 + h^3) - 2}{h} = \lim_{h \rightarrow 0} \frac{-h^3 - 3h^2 - h}{h} \\
 &= \lim_{h \rightarrow 0} \frac{h(-h^2 - 3h - 1)}{h} = \lim_{h \rightarrow 0} (-h^2 - 3h - 1) = -1
 \end{aligned}$$

$$\text{Tangent line: } y - 2 = -1(x - 1) \Leftrightarrow y - 2 = -x + 1 \Leftrightarrow y = -x + 3$$

8. Using (1),

$$\begin{aligned}
 m &= \lim_{x \rightarrow 4} \frac{\sqrt{2x+1} - \sqrt{2(4)+1}}{x-4} = \lim_{x \rightarrow 4} \frac{\sqrt{2x+1}-3}{x-4} \cdot \frac{\sqrt{2x+1}+3}{\sqrt{2x+1}+3} \\
 &= \lim_{x \rightarrow 4} \frac{(2x+1)-3^2}{(x-4)(\sqrt{2x+1}+3)} = \lim_{x \rightarrow 4} \frac{2(x-4)}{(x-4)(\sqrt{2x+1}+3)} \\
 &= \lim_{x \rightarrow 4} \frac{2}{(\sqrt{2x+1}+3)} = \frac{2}{3+3} = \frac{1}{3}.
 \end{aligned}$$

$$\text{Tangent line: } y-3 = \frac{1}{3}(x-4) \Leftrightarrow y-3 = \frac{1}{3}x - \frac{4}{3} \Leftrightarrow y = \frac{1}{3}x + \frac{5}{3}$$

9. Using (1) with $f(x) = \frac{x-1}{x-2}$ and $P(3, 2)$,

$$\begin{aligned}
 m &= \lim_{x \rightarrow 3} \frac{f(x) - f(a)}{x-a} = \lim_{x \rightarrow 3} \frac{\frac{x-1}{x-2} - 2}{x-3} = \lim_{x \rightarrow 3} \frac{\frac{x-1-2(x-2)}{x-2}}{x-3} = \lim_{x \rightarrow 3} \frac{3-x}{(x-2)(x-3)} \\
 &= \lim_{x \rightarrow 3} \frac{-1}{x-2} = \frac{-1}{1} = -1.
 \end{aligned}$$

$$\text{Tangent line: } y-2 = -1(x-3) \Leftrightarrow y-2 = -x+3 \Leftrightarrow y = -x+5$$

$$10. \text{ Using (1), } m = \lim_{x \rightarrow 0} \frac{\frac{2x}{(x+1)^2} - 0}{x-0} = \lim_{x \rightarrow 0} \frac{2x}{x(x+1)^2} = \lim_{x \rightarrow 0} \frac{2}{(x+1)^2} = \frac{2}{1^2} = 2.$$

$$\text{Tangent line: } y-0 = 2(x-0) \Leftrightarrow y = 2x$$

$$\begin{aligned}
 11. (a) \quad m &= \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x-a} = \lim_{x \rightarrow a} \frac{2/(x+3) - 2/(a+3)}{x-a} = \lim_{x \rightarrow a} \frac{2(a+3) - 2(x+3)}{(x-a)(x+3)(a+3)} \\
 &= \lim_{x \rightarrow a} \frac{2(a-x)}{(x-a)(x+3)(a+3)} = \lim_{x \rightarrow a} \frac{-2}{(x+3)(a+3)} = \frac{-2}{(a+3)^2}
 \end{aligned}$$

$$(b) \quad (i) \ a = -1 \Rightarrow m = \frac{-2}{(-1+3)^2} = -\frac{1}{2} \qquad (ii) \ a = 0 \Rightarrow m = \frac{-2}{(0+3)^2} = -\frac{2}{9}$$

$$(iii) \ a = 1 \Rightarrow m = \frac{-2}{(1+3)^2} = -\frac{1}{8}$$

12. (a) Using (1),

$$\begin{aligned}
 m &= \lim_{x \rightarrow a} \frac{(1+x+x^2) - (1+a+a^2)}{x-a} = \lim_{x \rightarrow a} \frac{x+x^2-a-a^2}{x-a} = \lim_{x \rightarrow a} \frac{x-a+(x-a)(x+a)}{x-a} \\
 &= \lim_{x \rightarrow a} \frac{(x-a)(1+x+a)}{x-a} = \lim_{x \rightarrow a} (1+x+a) = 1+2a
 \end{aligned}$$

$$(b) \quad (i) \ x = -1 \Rightarrow m = 1+2(-1) = -1$$

$$(ii) \ x = -\frac{1}{2} \Rightarrow m = 1+2\left(-\frac{1}{2}\right) = 0$$

$$(iii) \ x = 1 \Rightarrow m = 1+2(1) = 3$$

(c)

13. (a) Using (1),

$$\begin{aligned} m &= \lim_{x \rightarrow a} \frac{(x^3 - 4x + 1) - (a^3 - 4a + 1)}{x - a} = \lim_{x \rightarrow a} \frac{(x^3 - a^3) - 4(x - a)}{x - a} \\ &= \lim_{x \rightarrow a} \frac{(x - a)(x^2 + ax + a^2) - 4(x - a)}{x - a} = \lim_{x \rightarrow a} (x^2 + ax + a^2 - 4) = 3a^2 - 4 \end{aligned}$$

(b) At $(1, -2)$: $m = 3(1)^2 - 4 = -1$, so an equation of the tangent line

$$\text{is } y - (-2) = -1(x - 1) \Leftrightarrow y = -x - 1. \text{ At } (2, 1):$$

$$m = 3(2)^2 - 4 = 8, \text{ so an equation of the tangent line is}$$

$$y - 1 = 8(x - 2) \Leftrightarrow y = 8x - 15.$$

(c)

14. (a) Using (1),

$$\begin{aligned} m &= \lim_{x \rightarrow a} \frac{\frac{1}{\sqrt{x}} - \frac{1}{\sqrt{a}}}{x - a} = \lim_{x \rightarrow a} \frac{\frac{\sqrt{a} - \sqrt{x}}{\sqrt{ax}}}{x - a} = \lim_{x \rightarrow a} \frac{(\sqrt{a} - \sqrt{x})(\sqrt{a} + \sqrt{x})}{\sqrt{ax}(x - a)(\sqrt{a} + \sqrt{x})} \\ &= \lim_{x \rightarrow a} \frac{a - x}{\sqrt{ax}(x - a)(\sqrt{a} + \sqrt{x})} = \lim_{x \rightarrow a} \frac{-1}{\sqrt{ax}(\sqrt{a} + \sqrt{x})} = \frac{-1}{\sqrt{a^2}(2\sqrt{a})} = -\frac{1}{2a^{3/2}} \text{ or } -\frac{1}{2}a^{-3/2} \end{aligned}$$

(b) At $(1, 1)$: $m = -\frac{1}{2}$, so an equation of the tangent line is

$$y - 1 = -\frac{1}{2}(x - 1) \Leftrightarrow y = -\frac{1}{2}x + \frac{3}{2}.$$

At $(4, \frac{1}{2})$: $m = -\frac{1}{16}$, so an equation of the tangent line is

$$y - \frac{1}{2} = -\frac{1}{16}(x - 4) \Leftrightarrow y = -\frac{1}{16}x + \frac{3}{4}.$$

(c) 2

15. (a) Since the slope of the tangent at $t = 0$ is 0, the car's initial velocity was 0.

(b) The slope of the tangent is greater at C than at B , so the car was going faster at C .

(c) Near A , the tangent lines are becoming steeper as x increases, so the velocity was increasing, so the car was speeding up. Near B , the tangent lines are becoming less steep, so the car was slowing down. The steepest tangent near C is the one at C , so at C the car had just finished speeding up, and was about to start slowing down.

(d) Between D and E , the slope of the tangent is 0, so the car did not move during that time.

16. Let a denote the distance traveled from 1:00 to 1:02, b from 1:28 to 1:30, and c from 3:30 to 3:33, where all the times are relative to $t = 0$ at the beginning of the trip.

17. Let $s(t) = 40t - 16t^2$.

$$\begin{aligned} v(2) &= \lim_{t \rightarrow 2} \frac{s(t) - s(2)}{t - 2} = \lim_{t \rightarrow 2} \frac{(40t - 16t^2) - 16}{t - 2} = \lim_{t \rightarrow 2} \frac{-16t^2 + 40t - 16}{t - 2} = \lim_{t \rightarrow 2} \frac{-8(2t^2 - 5t + 2)}{t - 2} \\ &= \lim_{t \rightarrow 2} \frac{-8(t - 2)(2t - 1)}{t - 2} = -8 \lim_{t \rightarrow 2} (2t - 1) = -8(3) = -24 \end{aligned}$$

Thus, the instantaneous velocity when $t = 2$ is -24 ft/s.

$$\begin{aligned} 18. (a) \quad v(1) &= \lim_{h \rightarrow 0} \frac{H(1+h) - H(1)}{h} \\ &= \lim_{h \rightarrow 0} \frac{(58 + 58h - 0.83 - 1.66h - 0.83h^2) - 57.17}{h} = \lim_{h \rightarrow 0} (56.34 - 0.83h) = 56.34 \text{ m/s} \end{aligned}$$

$$\begin{aligned} (b) \quad v(a) &= \lim_{h \rightarrow 0} \frac{H(a+h) - H(a)}{h} \\ &= \lim_{h \rightarrow 0} \frac{(58a + 58h - 0.83a^2 - 1.66ah - 0.83h^2) - (58a - 0.83a^2)}{h} \\ &= \lim_{h \rightarrow 0} (58 - 1.66a - 0.83h) = 58 - 1.66a \text{ m/s} \end{aligned}$$

(c) The arrow strikes the moon when the height is 0, that is, $58t - 0.83t^2 = 0 \Leftrightarrow t(58 - 0.83t) = 0 \Leftrightarrow t = \frac{58}{0.83} \approx 69.9$ s (since t can't be 0).

(d) Using the time from part (c), $v\left(\frac{58}{0.83}\right) = 58 - 1.66\left(\frac{58}{0.83}\right) = -58$ m/s. Thus, the arrow will have a velocity of -58 m/s.

$$\begin{aligned} 19. \quad v(a) &= \lim_{h \rightarrow 0} \frac{s(a+h) - s(a)}{h} = \lim_{h \rightarrow 0} \frac{4(a+h)^3 + 6(a+h) + 2 - (4a^3 + 6a + 2)}{h} \\ &= \lim_{h \rightarrow 0} \frac{4a^3 + 12a^2h + 12ah^2 + 4h^3 + 6a + 6h + 2 - 4a^3 - 6a - 2}{h} \\ &= \lim_{h \rightarrow 0} \frac{12a^2h + 12ah^2 + 4h^3 + 6h}{h} = \lim_{h \rightarrow 0} (12a^2 + 12ah + 4h^2 + 6) = (12a^2 + 6) \text{ m/s} \end{aligned}$$

So $v(1) = 12(1)^2 + 6 = 18$ m/s, $v(2) = 12(2)^2 + 6 = 54$ m/s, and $v(3) = 12(3)^2 + 6 = 114$ m/s.

20. (a) The average velocity between times
- t
- and
- $t + h$
- is

$$\begin{aligned}\frac{s(t+h) - s(t)}{(t+h) - t} &= \frac{(t+h)^2 - 8(t+h) + 18 - (t^2 - 8t + 18)}{h} \\ &= \frac{t^2 + 2th + h^2 - 8t - 8h + 18 - t^2 + 8t - 18}{h} = \frac{2th + h^2 - 8h}{h} \\ &= (2t + h - 8) \text{ m/s}\end{aligned}$$

(i) $[3, 4]$: $t = 3$, $h = 4 - 3 = 1$, so the average velocity is $2(3) + 1 - 8 = -1$ m/s.(ii) $[3.5, 4]$: $t = 3.5$, $h = 0.5$, so the average velocity is $2(3.5) + 0.5 - 8 = -0.5$ m/s.(iii) $[4, 5]$: $t = 4$, $h = 1$, so the average velocity is $2(4) + 1 - 8 = 1$ m/s.(iv) $[4, 4.5]$: $t = 4$, $h = 0.5$, so the average velocity is $2(4) + 0.5 - 8 = 0.5$ m/s.

$$(b) v(t) = \lim_{h \rightarrow 0} \frac{s(t+h) - s(t)}{h} = \lim_{h \rightarrow 0} (2t + h - 8) = 2t - 8, \text{ so } v(4) = 0.$$

21. The sketch shows the graph for a room temperature of
- 72°
- and a refrigerator temperature of
- 38°
- . The initial rate of change is greater in magnitude than the rate of change after an hour.

22. The slope of the tangent (that is, the rate of change of temperature with respect to time) at
- $t = 1$
- h seems to be about
- $\frac{75 - 168}{132 - 0} \approx -0.7^\circ\text{F/min}$
- .

23. (a) (i) $[20, 23]$: $\frac{7.9 - 11.5}{23 - 20} = -1.2^\circ\text{C/h}$

(ii) $[20, 22]$: $\frac{9.0 - 11.5}{22 - 20} = -1.25^\circ\text{C/h}$

(iii) $[20, 21]$: $\frac{10.2 - 11.5}{21 - 20} = -1.3^\circ\text{C/h}$

- (b) In the figure, we estimate
- A
- to be
- $(18, 15.5)$
- and
- B
- as
- $(23, 6)$
- . So the slope is

$$\frac{6 - 15.5}{23 - 18} = -1.9^\circ\text{C/h at 8:00 P.M.}$$

24. (a) (i) [1992, 1996]: $\frac{P(1996) - P(1992)}{1996 - 1992} = \frac{10,152 - 10,036}{4} = \frac{116}{4} = 29$ thousand/year
- (ii) [1994, 1996]: $\frac{P(1996) - P(1994)}{1996 - 1994} = \frac{10,152 - 10,109}{2} = \frac{43}{2} = 21.5$ thousand/year
- (iii) [1996, 1998]: $\frac{P(1998) - P(1996)}{1998 - 1996} = \frac{10,175 - 10,152}{2} = \frac{23}{2} = 11.5$ thousand/year

(b) Using the values from (ii) and (iii), we have $\frac{21.5 + 11.5}{2} = 16.5$ thousand/year.

(c) Estimating A as (1994, 10,125) and B as

(1998, 10,182), the slope at 1996 is

$$\frac{10,182 - 10,125}{1998 - 1994} = \frac{57}{4} = 14.25 \text{ thousand/year.}$$

25. (a) (i) [1995, 1997]: $\frac{N(1997) - N(1995)}{1997 - 1995} = \frac{2461 - 873}{2} = \frac{1588}{2} = 794$ thousand/year
- (ii) [1995, 1996]: $\frac{N(1996) - N(1995)}{1996 - 1995} = \frac{1513 - 873}{1} = 640$ thousand/year
- (iii) [1994, 1995]: $\frac{N(1995) - N(1994)}{1995 - 1994} = \frac{873 - 572}{1} = 301$ thousand/year

(b) Using the values from (ii) and (iii), we have $\frac{640 + 301}{2} = \frac{941}{2} = 470.5$ thousand/year.

(c) Estimating A as (1994, 420) and B as (1996, 1275), the slope

$$\text{at 1995 is } \frac{1275 - 420}{1996 - 1994} = \frac{855}{2} = 427.5 \text{ thousand/year}$$

26. (a) (i) [1996, 1998]: $\frac{N(1998) - N(1996)}{1998 - 1996} = \frac{1886 - 1015}{2} = \frac{871}{2} = 435.5$ locations/year
- (ii) [1997, 1998]: $\frac{N(1998) - N(1997)}{1998 - 1997} = \frac{1886 - 1412}{1} = 474$ locations/year
- (iii) [1998, 1999]: $\frac{N(1999) - N(1998)}{1999 - 1998} = \frac{2135 - 1886}{1} = 249$ locations/year

(b) Using the values from (ii) and (iii), we have $\frac{474 + 249}{2} = \frac{723}{2} = 361.5 \approx 362$ locations/year.

(c) Estimating A as (1997, 1525) and B as (1999, 2250), the slope

$$\text{at 1998 is } \frac{2250 - 1525}{1999 - 1997} = \frac{725}{2} = 362.5 \text{ locations/year.}$$

$$27. (a) (i) \frac{\Delta C}{\Delta x} = \frac{C(105) - C(100)}{105 - 100} = \frac{6601.25 - 6500}{5} = \$20.25/\text{unit.}$$

$$(ii) \frac{\Delta C}{\Delta x} = \frac{C(101) - C(100)}{101 - 100} = \frac{6520.05 - 6500}{1} = \$20.05/\text{unit.}$$

$$(b) \frac{C(100 + h) - C(100)}{h} = \frac{[5000 + 10(100 + h) + 0.05(100 + h)^2] - 6500}{h} = \frac{20h + 0.05h^2}{h} \\ = 20 + 0.05h, h \neq 0$$

$$\text{So the instantaneous rate of change is } \lim_{h \rightarrow 0} \frac{C(100 + h) - C(100)}{h} = \lim_{h \rightarrow 0} (20 + 0.05h) = \$20/\text{unit.}$$

$$28. \Delta V = V(t + h) - V(t) = 100,000 \left(1 - \frac{t + h}{60}\right)^2 - 100,000 \left(1 - \frac{t}{60}\right)^2 \\ = 100,000 \left[\left(1 - \frac{t + h}{60} + \frac{(t + h)^2}{3600}\right) - \left(1 - \frac{t}{60} + \frac{t^2}{3600}\right) \right] = 100,000 \left(-\frac{h}{30} + \frac{2th}{3600} + \frac{h^2}{3600}\right) \\ = \frac{100,000}{3600} h (-120 + 2t + h) = \frac{250}{9} h (-120 + 2t + h)$$

Dividing ΔV by h and then letting $h \rightarrow 0$, we see that the instantaneous rate of change is $\frac{500}{9} (t - 60)$ gal/min.

t	Flow rate (gal/min)	Water remaining $V(t)$ (gal)
0	$-3333.\bar{3}$	100,000
10	$-2777.\bar{7}$	69,444. $\bar{4}$
20	$-2222.\bar{2}$	44,444. $\bar{4}$
30	$-1666.\bar{6}$	25,000
40	$-1111.\bar{1}$	11,111. $\bar{1}$
50	$-555.\bar{5}$	2,777. $\bar{7}$
60	0	0

The magnitude of the flow rate is greatest at the beginning and gradually decreases to 0.

44 □ CHAPTER 2 LIMITS AND RATES OF CHANGE

4. True. The limit doesn't exist since $f(x)/g(x)$ doesn't approach any real number as x approaches 5. (The denominator approaches 0 and the numerator doesn't.)
5. False. Consider $\lim_{x \rightarrow 5} \frac{x(x-5)}{x-5}$ or $\lim_{x \rightarrow 5} \frac{\sin(x-5)}{x-5}$. The first limit exists and is equal to 5. By Example 3 in Section 2.2, we know that the latter limit exists (and it is equal to 1).
6. False. Consider $\lim_{x \rightarrow 6} [f(x)g(x)] = \lim_{x \rightarrow 6} \left[(x-6) \frac{1}{x-6} \right]$. It exists (its value is 1) but $f(6) = 0$ and $g(6)$ does not exist, so $f(6)g(6) \neq 1$.
7. True. A polynomial is continuous everywhere, so $\lim_{x \rightarrow b} p(x)$ exists and is equal to $p(b)$.
8. False. Consider $\lim_{x \rightarrow 0} [f(x) - g(x)] = \lim_{x \rightarrow 0} \left(\frac{1}{x^2} - \frac{1}{x^4} \right)$. This limit is $-\infty$ (not 0), but each of the individual functions approaches ∞ .
9. False. Consider $f(x) = \begin{cases} 1/(x-1) & \text{if } x \neq 1 \\ 2 & \text{if } x = 1 \end{cases}$
10. False. The function f must be *continuous* in order to use the Intermediate Value Theorem. For example, let
$$f(x) = \begin{cases} 1 & \text{if } 0 \leq x < 3 \\ -1 & \text{if } x = 3 \end{cases}$$
 There is no number $c \in [0, 3]$ with $f(c) = 0$.
11. True. Use Theorem 2.5.8 with $a = 2$, $b = 5$, and $g(x) = 4x^2 - 11$. Note that $f(4) = 3$ is not needed.
12. True. Use the Intermediate Value Theorem with $a = -1$, $b = 1$, and $N = \pi$, since $3 < \pi < 4$.
13. True, by the definition of a limit with $\varepsilon = 1$.
14. False. For example, let $f(x) = \begin{cases} x^2 + 1 & \text{if } x \neq 0 \\ 2 & \text{if } x = 0 \end{cases}$
Then $f(x) > 1$ for all x , but $\lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} (x^2 + 1) = 1$.

EXERCISES

1. (a) (i) $\lim_{x \rightarrow 2^+} f(x) = 3$ (ii) $\lim_{x \rightarrow -3^+} f(x) = 0$
(iii) $\lim_{x \rightarrow -3} f(x)$ does not exist since the left and right limits are not equal. (The left limit is -2 .) (iv) $\lim_{x \rightarrow 4} f(x) = 2$
(v) $\lim_{x \rightarrow 0} f(x) = \infty$ (vi) $\lim_{x \rightarrow 2^-} f(x) = -\infty$
- (b) The equations of the vertical asymptotes are $x = 0$ and $x = 2$.
- (c) f is discontinuous at $x = -3, 0, 2$, and 4 . The discontinuities are jump, infinite, infinite, and removable, respectively.

2.

$$3. \lim_{x \rightarrow 0} \cos(x + \sin x) = \cos \left[\lim_{x \rightarrow 0} (x + \sin x) \right] \quad [\text{by Theorem 2.5.8}] = \cos 0 = 1$$

$$4. \text{ Since rational functions are continuous, } \lim_{x \rightarrow 3} \frac{x^2 - 9}{x^2 + 2x - 3} = \frac{3^2 - 9}{3^2 + 2(3) - 3} = \frac{0}{12} = 0.$$

$$5. \lim_{x \rightarrow -3} \frac{x^2 - 9}{x^2 + 2x - 3} = \lim_{x \rightarrow -3} \frac{(x+3)(x-3)}{(x+3)(x-1)} = \lim_{x \rightarrow -3} \frac{x-3}{x-1} = \frac{-3-3}{-3-1} = \frac{-6}{-4} = \frac{3}{2}$$

$$6. \lim_{x \rightarrow 1^+} \frac{x^2 - 9}{x^2 + 2x - 3} = -\infty \text{ since } x^2 + 2x - 3 \rightarrow 0 \text{ as } x \rightarrow 1^+ \text{ and } \frac{x^2 - 9}{x^2 + 2x - 3} < 0 \text{ for } 1 < x < 3.$$

$$7. \lim_{h \rightarrow 0} \frac{(h-1)^3 + 1}{h} = \lim_{h \rightarrow 0} \frac{(h^3 - 3h^2 + 3h - 1) + 1}{h} = \lim_{h \rightarrow 0} \frac{h^3 - 3h^2 + 3h}{h} = \lim_{h \rightarrow 0} (h^2 - 3h + 3) = 3$$

Another solution: Factor the numerator as a sum of two cubes and then simplify.

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{(h-1)^3 + 1}{h} &= \lim_{h \rightarrow 0} \frac{(h-1)^3 + 1^3}{h} = \lim_{h \rightarrow 0} \frac{[(h-1) + 1][(h-1)^2 - 1(h-1) + 1^2]}{h} \\ &= \lim_{h \rightarrow 0} [(h-1)^2 - h + 2] = 1 - 0 + 2 = 3 \end{aligned}$$

$$8. \lim_{t \rightarrow 2} \frac{t^2 - 4}{t^3 - 8} = \lim_{t \rightarrow 2} \frac{(t+2)(t-2)}{(t-2)(t^2 + 2t + 4)} = \lim_{t \rightarrow 2} \frac{t+2}{t^2 + 2t + 4} = \frac{2+2}{4+4+4} = \frac{4}{12} = \frac{1}{3}$$

$$9. \lim_{r \rightarrow 9} \frac{\sqrt{r}}{(r-9)^4} = \infty \text{ since } (r-9)^4 \rightarrow 0 \text{ as } r \rightarrow 9 \text{ and } \frac{\sqrt{r}}{(r-9)^4} > 0 \text{ for } r \neq 9.$$

$$10. \lim_{v \rightarrow 4^+} \frac{4-v}{|4-v|} = \lim_{v \rightarrow 4^+} \frac{4-v}{-(4-v)} = \lim_{v \rightarrow 4^+} \frac{1}{-1} = -1$$

$$11. \lim_{s \rightarrow 16} \frac{4-\sqrt{s}}{s-16} = \lim_{s \rightarrow 16} \frac{4-\sqrt{s}}{(\sqrt{s}+4)(\sqrt{s}-4)} = \lim_{s \rightarrow 16} \frac{-1}{\sqrt{s}+4} = \frac{-1}{\sqrt{16}+4} = -\frac{1}{8}$$

$$12. \lim_{v \rightarrow 2} \frac{v^2 + 2v - 8}{v^4 - 16} = \lim_{v \rightarrow 2} \frac{(v+4)(v-2)}{(v+2)(v-2)(v^2+4)} = \lim_{v \rightarrow 2} \frac{v+4}{(v+2)(v^2+4)} = \frac{2+4}{(2+2)(2^2+4)} = \frac{3}{16}$$

$$13. \frac{|x-8|}{x-8} = \begin{cases} \frac{x-8}{x-8} & \text{if } x-8 > 0 \\ \frac{-(x-8)}{x-8} & \text{if } x-8 < 0 \end{cases} = \begin{cases} 1 & \text{if } x > 8 \\ -1 & \text{if } x < 8 \end{cases}$$

$$\text{Thus, } \lim_{x \rightarrow 8^-} \frac{|x-8|}{x-8} = \lim_{x \rightarrow 8^-} (-1) = -1.$$

$$14. \lim_{x \rightarrow 9^+} (\sqrt{x-9} + \lfloor x+1 \rfloor) = \lim_{x \rightarrow 9^+} \sqrt{x-9} + \lim_{x \rightarrow 9^+} \lfloor x+1 \rfloor = \sqrt{9-9} + 10 = 10$$

$$15. \lim_{x \rightarrow 0} \frac{1 - \sqrt{1-x^2}}{x} \cdot \frac{1 + \sqrt{1-x^2}}{1 + \sqrt{1-x^2}} = \lim_{x \rightarrow 0} \frac{1 - (1-x^2)}{x(1 + \sqrt{1-x^2})} = \lim_{x \rightarrow 0} \frac{x^2}{x(1 + \sqrt{1-x^2})} = \lim_{x \rightarrow 0} \frac{x}{1 + \sqrt{1-x^2}} = 0$$

$$16. \lim_{x \rightarrow 2} \frac{\sqrt{x+2} - \sqrt{2x}}{x(x-2)} \cdot \frac{\sqrt{x+2} + \sqrt{2x}}{\sqrt{x+2} + \sqrt{2x}} = \lim_{x \rightarrow 2} \frac{-(x-2)}{x(x-2)(\sqrt{x+2} + \sqrt{2x})} = \lim_{x \rightarrow 2} \frac{-1}{x(\sqrt{x+2} + \sqrt{2x})} = -\frac{1}{8}$$

17. Since $2x - 1 \leq f(x) \leq x^2$ for $0 < x < 3$ and $\lim_{x \rightarrow 1} (2x - 1) = 1 = \lim_{x \rightarrow 1} x^2$, we have $\lim_{x \rightarrow 1} f(x) = 1$ by the Squeeze Theorem.
18. Let $f(x) = -x^2$, $g(x) = x^2 \cos(1/x^2)$ and $h(x) = x^2$. Then since $|\cos(1/x^2)| \leq 1$ for $x \neq 0$, we have $f(x) \leq g(x) \leq h(x)$ for $x \neq 0$, and so $\lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} h(x) = 0 \Rightarrow \lim_{x \rightarrow 0} g(x) = 0$ by the Squeeze Theorem.
19. Given $\varepsilon > 0$, we need $\delta > 0$ so that if $0 < |x - 5| < \delta$, then $|(7x - 27) - 8| < \varepsilon \Leftrightarrow |7x - 35| < \varepsilon \Leftrightarrow |x - 5| < \varepsilon/7$. So take $\delta = \varepsilon/7$. Then $0 < |x - 5| < \delta \Rightarrow |(7x - 27) - 8| < \varepsilon$. Thus, $\lim_{x \rightarrow 5} (7x - 27) = 8$ by the definition of a limit.
20. Given $\varepsilon > 0$ we must find $\delta > 0$ so that if $0 < |x - 0| < \delta$, then $|\sqrt[3]{x} - 0| < \varepsilon$. Now $|\sqrt[3]{x} - 0| = |\sqrt[3]{x}| < \varepsilon \Rightarrow |x| = |\sqrt[3]{x}|^3 < \varepsilon^3$. So take $\delta = \varepsilon^3$. Then $0 < |x - 0| = |x| < \varepsilon^3 \Rightarrow |\sqrt[3]{x} - 0| = |\sqrt[3]{x}| = \sqrt[3]{|x|} < \sqrt[3]{\varepsilon^3} = \varepsilon$. Therefore, by the definition of a limit, $\lim_{x \rightarrow 0} \sqrt[3]{x} = 0$.
21. Given $\varepsilon > 0$, we need $\delta > 0$ so that if $0 < |x - 2| < \delta$, then $|x^2 - 3x - (-2)| < \varepsilon$. First, note that if $|x - 2| < 1$, then $-1 < x - 2 < 1$, so $0 < x - 1 < 2 \Rightarrow |x - 1| < 2$. Now let $\delta = \min\{\varepsilon/2, 1\}$. Then $0 < |x - 2| < \delta \Rightarrow |x^2 - 3x - (-2)| = |(x - 2)(x - 1)| = |x - 2||x - 1| < (\varepsilon/2)(2) = \varepsilon$. Thus, $\lim_{x \rightarrow 2} (x^2 - 3x) = -2$ by the definition of a limit.
22. Given $M > 0$, we need $\delta > 0$ such that if $0 < x - 4 < \delta$, then $2/\sqrt{x - 4} > M$. This is true $\Leftrightarrow \sqrt{x - 4} < 2/M \Leftrightarrow x - 4 < 4/M^2$. So if we choose $\delta = 4/M^2$, then $0 < x - 4 < \delta \Rightarrow 2/\sqrt{x - 4} > M$. So by the definition of a limit, $\lim_{x \rightarrow 4^+} (2/\sqrt{x - 4}) = \infty$.
23. (a) $f(x) = \sqrt{-x}$ if $x < 0$, $f(x) = 3 - x$ if $0 \leq x < 3$, $f(x) = (x - 3)^2$ if $x > 3$.
- (i) $\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} (3 - x) = 3$ (ii) $\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^-} \sqrt{-x} = 0$
- (iii) Because of (i) and (ii), $\lim_{x \rightarrow 0} f(x)$ does not exist. (iv) $\lim_{x \rightarrow 3^-} f(x) = \lim_{x \rightarrow 3^-} (3 - x) = 0$
- (v) $\lim_{x \rightarrow 3^+} f(x) = \lim_{x \rightarrow 3^+} (x - 3)^2 = 0$ (vi) Because of (iv) and (v), $\lim_{x \rightarrow 3} f(x) = 0$.
- (b) f is discontinuous at 0 since $\lim_{x \rightarrow 0} f(x)$ does not exist.
- f is discontinuous at 3 since $f(3)$ does not exist.

24. (a) $g(x) = 2x - x^2$ if $0 \leq x \leq 2$, $g(x) = 2 - x$ if $2 < x \leq 3$, $g(x) = x - 4$ if $3 < x < 4$, $g(x) = \pi$ if $x \geq 4$. Therefore,
- $\lim_{x \rightarrow 2^-} g(x) = \lim_{x \rightarrow 2^-} (2x - x^2) = 0$ and $\lim_{x \rightarrow 2^+} g(x) = \lim_{x \rightarrow 2^+} (2 - x) = 0$. Thus, $\lim_{x \rightarrow 2} g(x) = 0 = g(2)$, so g is continuous at 2.
- $\lim_{x \rightarrow 3^-} g(x) = \lim_{x \rightarrow 3^-} (2 - x) = -1$ and $\lim_{x \rightarrow 3^+} g(x) = \lim_{x \rightarrow 3^+} (x - 4) = -1$. Thus, $\lim_{x \rightarrow 3} g(x) = -1 = g(3)$, so g is continuous at 3.
- $\lim_{x \rightarrow 4^-} g(x) = \lim_{x \rightarrow 4^-} (x - 4) = 0$ and $\lim_{x \rightarrow 4^+} g(x) = \lim_{x \rightarrow 4^+} \pi = \pi$. Thus, $\lim_{x \rightarrow 4} g(x)$ does not exist, so g is discontinuous at 4. But $\lim_{x \rightarrow 4^+} g(x) = \pi = g(4)$, so g is continuous from the right at 4.
- (b)

25. x^3 is continuous on $\mathbb{R}$ since it is a polynomial and $\cos x$ is also continuous on $\mathbb{R}$, so the product $x^3 \cos x$ is continuous on $\mathbb{R}$. The root function $\sqrt[4]{x}$ is continuous on its domain, $[0, \infty)$, and so the sum, $h(x) = \sqrt[4]{x} + x^3 \cos x$, is continuous on its domain, $[0, \infty)$.
26. $x^2 - 9$ is continuous on $\mathbb{R}$ since it is a polynomial and $\sqrt{x}$ is continuous on $[0, \infty)$, so the composition $\sqrt{x^2 - 9}$ is continuous on $\{x \mid x^2 - 9 \geq 0\} = (-\infty, -3] \cup [3, \infty)$. Note that $x^2 - 2 \neq 0$ on this set and so the quotient function $g(x) = \frac{\sqrt{x^2 - 9}}{x^2 - 2}$ is continuous on its domain, $(-\infty, -3] \cup [3, \infty)$.
27. $f(x) = 2x^3 + x^2 + 2$ is a polynomial, so it is continuous on $[-2, -1]$ and $f(-2) = -10 < 0 < 1 = f(-1)$. So by the Intermediate Value Theorem there is a number c in $(-2, -1)$ such that $f(c) = 0$, that is, the equation $2x^3 + x^2 + 2 = 0$ has a root in $(-2, -1)$.
28. Let $f(x) = 2 \sin x - 3 + 2x$. Now f is continuous on $[0, 1]$ and $f(0) = -3 < 0$ and $f(1) = 2 \sin 1 - 1 \approx 0.68 > 0$. So by the Intermediate Value Theorem there is a number c in $(0, 1)$ such that $f(c) = 0$, that is, the equation $2 \sin x = 3 - 2x$ has a root in $(0, 1)$.

29. (a) The slope of the tangent line at $(2, 1)$ is

$$\begin{aligned} \lim_{x \rightarrow 2} \frac{f(x) - f(2)}{x - 2} &= \lim_{x \rightarrow 2} \frac{9 - 2x^2 - 1}{x - 2} = \lim_{x \rightarrow 2} \frac{8 - 2x^2}{x - 2} = \lim_{x \rightarrow 2} \frac{-2(x^2 - 4)}{x - 2} = \lim_{x \rightarrow 2} \frac{-2(x - 2)(x + 2)}{x - 2} \\ &= \lim_{x \rightarrow 2} [-2(x + 2)] = -2 \cdot 4 = -8 \end{aligned}$$

(b) An equation of this tangent line is $y - 1 = -8(x - 2)$ or $y = -8x + 17$.

30. For a general point with x -coordinate a , we have

$$\begin{aligned} m &= \lim_{x \rightarrow a} \frac{2/(1 - 3x) - 2/(1 - 3a)}{x - a} = \lim_{x \rightarrow a} \frac{2(1 - 3a) - 2(1 - 3x)}{(1 - 3a)(1 - 3x)(x - a)} \\ &= \lim_{x \rightarrow a} \frac{6(x - a)}{(1 - 3a)(1 - 3x)(x - a)} = \lim_{x \rightarrow a} \frac{6}{(1 - 3a)(1 - 3x)} = \frac{6}{(1 - 3a)^2} \end{aligned}$$

For $a = 0$, $m = 6$ and $f(0) = 2$, so an equation of the tangent line is $y - 2 = 6(x - 0)$ or $y = 6x + 2$. For $a = -1$, $m = \frac{3}{8}$ and $f(-1) = \frac{1}{2}$, so an equation of the tangent line is $y - \frac{1}{2} = \frac{3}{8}(x + 1)$ or $y = \frac{3}{8}x + \frac{7}{8}$.

31. (a) $s = s(t) = 1 + 2t + t^2/4$. The average velocity over the time interval $[1, 1 + h]$ is

$$v_{\text{ave}} = \frac{s(1 + h) - s(1)}{(1 + h) - 1} = \frac{1 + 2(1 + h) + (1 + h)^2/4 - 13/4}{h} = \frac{10h + h^2}{4h} = \frac{10 + h}{4}.$$

So for the following intervals the average velocities are:

- (i) $[1, 3]$: $h = 2$, $v_{\text{ave}} = (10 + 2)/4 = 3$ m/s
- (ii) $[1, 2]$: $h = 1$, $v_{\text{ave}} = (10 + 1)/4 = 2.75$ m/s
- (iii) $[1, 1.5]$: $h = 0.5$, $v_{\text{ave}} = (10 + 0.5)/4 = 2.625$ m/s
- (iv) $[1, 1.1]$: $h = 0.1$, $v_{\text{ave}} = (10 + 0.1)/4 = 2.525$ m/s

(b) When $t = 1$, the instantaneous velocity is $\lim_{h \rightarrow 0} \frac{s(1 + h) - s(1)}{h} = \lim_{h \rightarrow 0} \frac{10 + h}{4} = \frac{10}{4} = 2.5$ m/s.

32. (a) When V increases from 200 in^3 to 250 in^3 , we have $\Delta V = 250 - 200 = 50 \text{ in}^3$, and since $P = 800/V$,

$$\Delta P = P(250) - P(200) = \frac{800}{250} - \frac{800}{200} = 3.2 - 4 = -0.8 \text{ lb/in}^2. \text{ So the average rate of change is}$$

$$\frac{\Delta P}{\Delta V} = \frac{-0.8}{50} = -0.016 \frac{\text{lb/in}^2}{\text{in}^3}.$$

- (b) Since $V = 800/P$, the instantaneous rate of change of V with respect to P is

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{\Delta V}{\Delta P} &= \lim_{h \rightarrow 0} \frac{V(P+h) - V(P)}{h} = \lim_{h \rightarrow 0} \frac{800/(P+h) - 800/P}{h} \\ &= \lim_{h \rightarrow 0} \frac{800[P - (P+h)]}{h(P+h)P} = \lim_{h \rightarrow 0} \frac{-800}{(P+h)P} = -\frac{800}{P^2} \end{aligned}$$

which is inversely proportional to the square of P .

33. $\left| \frac{x+1}{x-1} - 3 \right| < 0.2 \Rightarrow -0.2 < \frac{x+1}{x-1} - 3 < 0.2 \Rightarrow$

$$2.8 < \frac{x+1}{x-1} < 3.2. \text{ Graphing the functions } y = 2.8,$$

$y = (x+1)/(x-1)$, and $y = 3.2$ on the interval $[1.8, 2.2]$, we see

that the inequality holds whenever $1.91 < x < 2.11$ (approximately).

So since $|2 - 1.91| = 0.09$ and $|2 - 2.11| = 0.11$, any positive

$\delta \leq 0.09$ will do.

34. The slope of the tangent to $y = \frac{x+1}{x-1}$ is

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{\frac{(x+h)+1}{(x+h)-1} - \frac{x+1}{x-1}}{h} &= \lim_{h \rightarrow 0} \frac{(x-1)(x+h+1) - (x+1)(x+h-1)}{h(x-1)(x+h-1)} \\ &= \lim_{h \rightarrow 0} \frac{-2h}{h(x-1)(x+h-1)} = -\frac{2}{(x-1)^2} \end{aligned}$$

$$\text{So at } (2, 3), m = -\frac{2}{(2-1)^2} = -2 \Rightarrow y - 3 = -2(x - 2) \Rightarrow$$

$$y = -2x + 7. \text{ At } (-1, 0), m = -\frac{2}{(-1-1)^2} = -\frac{1}{2} \Rightarrow$$

$$y = -\frac{1}{2}(x+1) \Rightarrow y = -\frac{1}{2}x - \frac{1}{2}.$$

35. $|f(x)| \leq g(x) \Leftrightarrow -g(x) \leq f(x) \leq g(x)$ and $\lim_{x \rightarrow a} g(x) = 0 = \lim_{x \rightarrow a} -g(x)$. Thus, by the Squeeze Theorem,

$$\lim_{x \rightarrow a} f(x) = 0.$$

36. (a) Note that f is an even function since $f(x) = f(-x)$. Now for any integer n , $\llbracket n \rrbracket + \llbracket -n \rrbracket = n - n = 0$, and for any real number k which is not an integer,

$$\llbracket k \rrbracket + \llbracket -k \rrbracket = \llbracket k \rrbracket + (-\llbracket k \rrbracket - 1) = -1. \text{ So } \lim_{x \rightarrow a} f(x) \text{ exists}$$

(and is equal to -1) for all values of a .

- (b) f is discontinuous at all integers.

PROBLEMS PLUS

1. Let $t = \sqrt[3]{x}$, so $x = t^3$. Then $t \rightarrow 1$ as $x \rightarrow 1$, so

$$\lim_{x \rightarrow 1} \frac{\sqrt[3]{x} - 1}{\sqrt{x} - 1} = \lim_{t \rightarrow 1} \frac{t^3 - 1}{t^3 - 1} = \lim_{t \rightarrow 1} \frac{(t-1)(t^2+t+1)}{(t-1)(t^2+t+1)} = \lim_{t \rightarrow 1} \frac{t+1}{t^2+t+1} = \frac{1+1}{1^2+1+1} = \frac{2}{3}.$$

Another method: Multiply both the numerator and the denominator by $(\sqrt{x} + 1)(\sqrt[3]{x^2} + \sqrt[3]{x} + 1)$.

2. First rationalize the numerator: $\lim_{x \rightarrow 0} \frac{\sqrt{ax+b}-2}{x} \cdot \frac{\sqrt{ax+b}+2}{\sqrt{ax+b}+2} = \lim_{x \rightarrow 0} \frac{ax+b-4}{x(\sqrt{ax+b}+2)}$. Now since the

denominator approaches 0 as $x \rightarrow 0$, the limit will exist only if the numerator also approaches 0 as $x \rightarrow 0$. So we require that $a(0) + b - 4 = 0 \Rightarrow b = 4$. So the equation becomes

$$\lim_{x \rightarrow 0} \frac{a}{\sqrt{ax+4}+2} = 1 \Rightarrow \frac{a}{\sqrt{4}+2} = 1 \Rightarrow a = 4. \text{ Therefore, } a = b = 4.$$

3. For $-\frac{1}{2} < x < \frac{1}{2}$, we have $2x - 1 < 0$ and $2x + 1 > 0$, so $|2x - 1| = -(2x - 1)$ and $|2x + 1| = 2x + 1$.

$$\text{Therefore, } \lim_{x \rightarrow 0} \frac{|2x-1| - |2x+1|}{x} = \lim_{x \rightarrow 0} \frac{-(2x-1) - (2x+1)}{x} = \lim_{x \rightarrow 0} \frac{-4x}{x} = \lim_{x \rightarrow 0} (-4) = -4.$$

4. Let R be the midpoint of OP , so the coordinates of R are $(\frac{1}{2}x, \frac{1}{2}x^2)$ since the coordinates of P are (x, x^2) . Let

$Q = (0, a)$. Since the slope $m_{OP} = \frac{x^2}{x} = x$, $m_{QR} = -\frac{1}{x}$ (negative reciprocal). But

$$m_{QR} = \frac{\frac{1}{2}x^2 - a}{\frac{1}{2}x - 0} = \frac{x^2 - 2a}{x}, \text{ so we conclude that } -1 = \frac{x^2 - 2a}{x} \Rightarrow 2a = x^2 + 1 \Rightarrow a = \frac{1}{2}x^2 + \frac{1}{2}.$$

As $x \rightarrow 0$, $a \rightarrow \frac{1}{2}$, and the limiting position of Q is $(0, \frac{1}{2})$.

5. Since $[x] \leq x < [x] + 1$, we have $\frac{[x]}{[x]} \leq \frac{x}{[x]} < \frac{[x]+1}{[x]} \Rightarrow 1 \leq \frac{x}{[x]} < 1 + \frac{1}{[x]}$ for $x \geq 1$. As $x \rightarrow \infty$, $[x] \rightarrow \infty$, so $\frac{1}{[x]} \rightarrow 0$ and $1 + \frac{1}{[x]} \rightarrow 1$. Thus, $\lim_{x \rightarrow \infty} \frac{x}{[x]} = 1$ by the Squeeze Theorem.

6. (a) $[x]^2 + [y]^2 = 1$. Since $[x]^2$ and $[y]^2$ are positive integers or 0, there are only 4 cases:

$$\text{Case (i): } [x] = 1, [y] = 0 \Rightarrow 1 \leq x < 2 \text{ and } 0 \leq y < 1$$

$$\text{Case (ii): } [x] = -1, [y] = 0 \Rightarrow -1 \leq x < 0 \text{ and } 0 \leq y < 1$$

$$\text{Case (iii): } [x] = 0, [y] = 1 \Rightarrow 0 \leq x < 1 \text{ and } 1 \leq y < 2$$

$$\text{Case (iv): } [x] = 0, [y] = -1 \Rightarrow 0 \leq x < 1 \text{ and } -1 \leq y < 0$$

- (b) $[x]^2 - [y]^2 = 3$. The only integral solution of $n^2 - m^2 = 3$ is $n = \pm 2$ and $m = \pm 1$. So the graph is

$$\{(x, y) \mid [x] = \pm 2, [y] = \pm 1\} =$$

$$\left\{ (x, y) \mid \begin{array}{l} 2 \leq x < 3 \text{ or } -2 \leq x < -1, \\ 1 \leq y < 2 \text{ or } -1 \leq y < 0 \end{array} \right\}.$$

$$\begin{aligned} (c) \quad [x+y]^2 = 1 &\Rightarrow [x+y] = \pm 1 \\ &\Rightarrow 1 \leq x+y < 2 \text{ or} \\ &\quad -1 \leq x+y < 0 \end{aligned}$$

$$\begin{aligned} (d) \quad \text{For } n \leq x < n+1, [x] = n. \text{ Then } [x] + [y] = 1 &\Rightarrow \\ [y] = 1-n &\Rightarrow 1-n \leq y < 2-n. \text{ Choosing integer} \\ \text{values for } n &\text{ produces the graph.} \end{aligned}$$

7. f is continuous on $(-\infty, a)$ and (a, ∞) . To make f continuous on $\mathbb{R}$, we must have continuity at a . Thus,

$$\begin{aligned} \lim_{x \rightarrow a^+} f(x) = \lim_{x \rightarrow a^-} f(x) &\Rightarrow \lim_{x \rightarrow a^+} x^2 = \lim_{x \rightarrow a^-} (x+1) \Rightarrow a^2 = a+1 \Rightarrow a^2 - a - 1 = 0 \Rightarrow \\ \text{[by the quadratic formula]} \quad a &= (1 \pm \sqrt{5})/2 \approx 1.618 \text{ or } -0.618. \end{aligned}$$

8. (a) Here are a few possibilities:

- (b) The “obstacle” is the line $x = y$ (see diagram). Any intersection of the graph of f with the line $y = x$ constitutes a fixed point, and if the graph of the function does not cross the line somewhere in $(0, 1)$, then it must either start at $(0, 0)$ (in which case 0 is a fixed point) or finish at $(1, 1)$ (in which case 1 is a fixed point).

- (c) Consider the function $F(x) = f(x) - x$, where f is any continuous function with domain $[0, 1]$ and range in $[0, 1]$. We shall prove that f has a fixed point.

Now if $f(0) = 0$ then we are done: f has a fixed point (the number 0), which is what we are trying to prove.

So assume $f(0) \neq 0$. For the same reason we can assume that $f(1) \neq 1$. Then $F(0) = f(0) > 0$ and

$F(1) = f(1) - 1 < 0$. So by the Intermediate Value Theorem, there exists some number c in the interval $(0, 1)$ such that $F(c) = f(c) - c = 0$. So $f(c) = c$, and therefore f has a fixed point.

$$9. \quad \lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} \left(\frac{1}{2} [f(x) + g(x)] + \frac{1}{2} [f(x) - g(x)] \right)$$

$$= \frac{1}{2} \lim_{x \rightarrow a} [f(x) + g(x)] + \frac{1}{2} \lim_{x \rightarrow a} [f(x) - g(x)]$$

$$= \frac{1}{2} \cdot 2 + \frac{1}{2} \cdot 1 = \frac{3}{2}, \text{ and}$$

$$\lim_{x \rightarrow a} g(x) = \lim_{x \rightarrow a} \left([f(x) + g(x)] - f(x) \right) = \lim_{x \rightarrow a} [f(x) + g(x)] - \lim_{x \rightarrow a} f(x) = 2 - \frac{3}{2} = \frac{1}{2}.$$

$$\text{So } \lim_{x \rightarrow a} [f(x)g(x)] = \left[\lim_{x \rightarrow a} f(x) \right] \left[\lim_{x \rightarrow a} g(x) \right] = \frac{3}{2} \cdot \frac{1}{2} = \frac{3}{4}.$$

Another solution: Since $\lim_{x \rightarrow a} [f(x) + g(x)]$ and $\lim_{x \rightarrow a} [f(x) - g(x)]$ exist, we must have

$$\begin{aligned} \lim_{x \rightarrow a} [f(x) + g(x)]^2 &= \left(\lim_{x \rightarrow a} [f(x) + g(x)] \right)^2 \text{ and } \lim_{x \rightarrow a} [f(x) - g(x)]^2 = \left(\lim_{x \rightarrow a} [f(x) - g(x)] \right)^2, \text{ so} \\ \lim_{x \rightarrow a} [f(x)g(x)] &= \lim_{x \rightarrow a} \frac{1}{4} ([f(x) + g(x)]^2 - [f(x) - g(x)]^2) \quad [\text{because all of the } f^2 \text{ and } g^2 \text{ cancel}] \\ &= \frac{1}{4} \left(\lim_{x \rightarrow a} [f(x) + g(x)]^2 - \lim_{x \rightarrow a} [f(x) - g(x)]^2 \right) = \frac{1}{4} (2^2 - 1^2) = \frac{3}{4}. \end{aligned}$$

10. (a) *Solution 1:* We introduce a coordinate system and drop a perpendicular

from P , as shown. We see from $\angle NCP$ that $\tan 2\theta = \frac{y}{1-x}$, and

from $\angle NBP$ that $\tan \theta = y/x$. Using the double-angle formula for

tangents, we get $\frac{y}{1-x} = \tan 2\theta = \frac{2 \tan \theta}{1 - \tan^2 \theta} = \frac{2(y/x)}{1 - (y/x)^2}$.

After a bit of simplification, this becomes $\frac{1}{1-x} = \frac{2x}{x^2 - y^2} \Leftrightarrow$

$y^2 = x(3x - 2)$. As the altitude AM decreases in length, the point P will approach the x -axis, that is, $y \rightarrow 0$, so the limiting location of P must be one of the roots of the equation $x(3x - 2) = 0$. Obviously it is not $x = 0$ (the point P can never be to the left of the altitude AM , which it would have to be in order to approach 0) so it must be $3x - 2 = 0$, that is, $x = \frac{2}{3}$.

Solution 2: We add a few lines to the original diagram, as shown. Now

note that $\angle BPQ = \angle PBC$ (alternate angles; $QP \parallel BC$ by

symmetry) and similarly $\angle CQP = \angle QCB$. So $\triangle BPQ$ and $\triangle CQP$

are isosceles, and the line segments BQ , QP and PC are all of equal length. As $|AM| \rightarrow 0$, P and Q approach points on the base, and the point P is seen to approach a position two-thirds of the way between B and C , as above.

- (b) The equation $y^2 = x(3x - 2)$ calculated in part (a) is the equation of the curve traced out by P . Now as $|AM| \rightarrow \infty$, $2\theta \rightarrow \frac{\pi}{2}$, $\theta \rightarrow \frac{\pi}{4}$, $x \rightarrow 1$, and since $\tan \theta = y/x$, $y \rightarrow 1$. Thus, P only traces out the part of the curve with $0 \leq y < 1$.

11. (a) Consider $G(x) = T(x + 180^\circ) - T(x)$. Fix any number a . If $G(a) = 0$, we are done:

Temperature at a = Temperature at $a + 180^\circ$. If $G(a) > 0$, then $G(a + 180^\circ) = T(a + 360^\circ) - T(a + 180^\circ) = T(a) - T(a + 180^\circ) = -G(a) < 0$. Also, G is continuous since temperature varies continuously. So, by the Intermediate Value Theorem, G has a zero on the interval $[a, a + 180^\circ]$. If $G(a) < 0$, then a similar argument applies.

- (b) Yes. The same argument applies.

- (c) The same argument applies for quantities that vary continuously, such as barometric pressure. But one could argue that altitude above sea level is sometimes discontinuous, so the result might not always hold for that quantity.

3 □ DERIVATIVES

3.1 Derivatives

The line from $P(2, f(2))$ to $Q(2+h, f(2+h))$ is the line that has slope $\frac{f(2+h) - f(2)}{h}$.

2. As h decreases, the line PQ becomes steeper, so its slope increases. So

$$0 < \frac{f(4) - f(2)}{4 - 2} < \frac{f(3) - f(2)}{3 - 2} < \lim_{x \rightarrow 2} \frac{f(x) - f(2)}{x - 2}. \text{ Thus, } 0 < \frac{1}{2} [f(4) - f(2)] < f(3) - f(2) < f'(2).$$

3. $g'(0)$ is the only negative value. The slope at $x = 4$ is smaller than the slope at $x = 2$ and both are smaller than the slope at $x = -2$. Thus, $g'(0) < 0 < g'(4) < g'(2) < g'(-2)$.

4. Since $(4, 3)$ is on $y = f(x)$, $f(4) = 3$. The slope of the tangent line between $(0, 2)$ and $(4, 3)$ is $\frac{1}{4}$, so $f'(4) = \frac{1}{4}$.

5. We begin by drawing a curve through the origin at a slope of 3 to satisfy $f(0) = 0$ and $f'(0) = 3$. Since $f'(1) = 0$, we will round off our figure so that there is a horizontal tangent directly over $x = 1$. Lastly, we make sure that the curve has a slope of -1 as we pass over $x = 2$. Two of the many possibilities are shown.

7. Using Definition 2 with $f(x) = 3x^2 - 5x$ and the point $(2, 2)$, we have

$$\begin{aligned} f'(2) &= \lim_{h \rightarrow 0} \frac{f(2+h) - f(2)}{h} = \lim_{h \rightarrow 0} \frac{[3(2+h)^2 - 5(2+h)] - 2}{h} \\ &= \lim_{h \rightarrow 0} \frac{(12 + 12h + 3h^2 - 10 - 5h) - 2}{h} = \lim_{h \rightarrow 0} \frac{3h^2 + 7h}{h} = \lim_{h \rightarrow 0} (3h + 7) = 7. \end{aligned}$$

So an equation of the tangent line at $(2, 2)$ is $y - 2 = 7(x - 2)$ or $y = 7x - 12$.

8. Using Definition 2 with $g(x) = 1 - x^3$ and the point $(0, 1)$, we have

$$g'(0) = \lim_{h \rightarrow 0} \frac{g(0+h) - g(0)}{h} = \lim_{h \rightarrow 0} \frac{[1 - (0+h)^3] - 1}{h} = \lim_{h \rightarrow 0} \frac{(1 - h^3) - 1}{h} = \lim_{h \rightarrow 0} (-h^2) = 0.$$

So an equation of the tangent line is $y - 1 = 0(x - 0)$ or $y = 1$.

9. (a) Using Definition 2 with $F(x) = x^3 - 5x + 1$ and the point $(1, -3)$, we have

$$\begin{aligned} F'(1) &= \lim_{h \rightarrow 0} \frac{F(1+h) - F(1)}{h} = \lim_{h \rightarrow 0} \frac{[(1+h)^3 - 5(1+h) + 1] - (-3)}{h} \\ &= \lim_{h \rightarrow 0} \frac{(1 + 3h + 3h^2 + h^3 - 5 - 5h + 1) + 3}{h} = \lim_{h \rightarrow 0} \frac{h^3 + 3h^2 - 2h}{h} \\ &= \lim_{h \rightarrow 0} \frac{h(h^2 + 3h - 2)}{h} = \lim_{h \rightarrow 0} (h^2 + 3h - 2) = -2 \end{aligned}$$

So an equation of the tangent line at $(1, -3)$ is $y - (-3) = -2(x - 1) \Leftrightarrow y = -2x - 1$.

10. (a) $G'(a) = \lim_{h \rightarrow 0} \frac{G(a+h) - G(a)}{h} = \lim_{h \rightarrow 0} \frac{\frac{a+h}{1+2(a+h)} - \frac{a}{1+2a}}{h}$

$$= \lim_{h \rightarrow 0} \frac{a + 2a^2 + h + 2ah - a - 2a^2 - 2ah}{h(1+2a+2h)(1+2a)} = \lim_{h \rightarrow 0} \frac{1}{(1+2a+2h)(1+2a)} = (1+2a)^{-2}$$

So the slope of the tangent at the point $(-\frac{1}{4}, -\frac{1}{2})$ is

$$m = [1 + 2(-\frac{1}{4})]^{-2} = 4, \text{ and thus an equation is}$$

$$y + \frac{1}{2} = 4(x + \frac{1}{4}) \text{ or } y = 4x + \frac{1}{2}.$$

11. (a) $f'(1) = \lim_{h \rightarrow 0} \frac{f(1+h) - f(1)}{h} = \lim_{h \rightarrow 0} \frac{3^{1+h} - 3^1}{h}.$

So let $F(h) = \frac{3^{1+h} - 3}{h}$. We calculate:

h	$F(h)$	h	$F(h)$
0.1	3.484	-0.1	3.121
0.01	3.314	-0.01	3.278
0.001	3.298	-0.001	3.294
0.0001	3.296	-0.0001	3.296

We estimate that $f'(1) \approx 3.296$.

From the graph, we estimate that the slope of the tangent is about

$$\frac{3.2 - 2.8}{1.06 - 0.94} = \frac{0.4}{0.12} \approx 3.3.$$

$$12. (a) g'\left(\frac{\pi}{4}\right) = \lim_{h \rightarrow 0} \frac{g\left(\frac{\pi}{4} + h\right) - g\left(\frac{\pi}{4}\right)}{h}$$

$$= \lim_{h \rightarrow 0} \frac{\tan\left(\frac{\pi}{4} + h\right) - \tan\left(\frac{\pi}{4}\right)}{h}.$$

$$\text{So let } G(h) = \frac{\tan\left(\frac{\pi}{4} + h\right) - 1}{h}.$$

We calculate:

h	$G(h)$	h	$G(h)$
0.1	2.2305	-0.1	1.8237
0.01	2.0203	-0.01	1.9803
0.001	2.0020	-0.001	1.9980
0.0001	2.0002	-0.0001	1.9998

We estimate that $g'\left(\frac{\pi}{4}\right) = 2$.

(b)

From the graph, we estimate that the slope of the

$$\text{tangent is about } \frac{1.07 - 0.91}{0.82 - 0.74} = \frac{0.16}{0.08} = 2.$$

13. Use Definition 2 with $f(x) = 3 - 2x + 4x^2$.

$$f'(a) = \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{h \rightarrow 0} \frac{[3 - 2(a+h) + 4(a+h)^2] - (3 - 2a + 4a^2)}{h}$$

$$= \lim_{h \rightarrow 0} \frac{(3 - 2a - 2h + 4a^2 + 8ah + 4h^2) - (3 - 2a + 4a^2)}{h}$$

$$= \lim_{h \rightarrow 0} \frac{-2h + 8ah + 4h^2}{h} = \lim_{h \rightarrow 0} \frac{h(-2 + 8a + 4h)}{h} = \lim_{h \rightarrow 0} (-2 + 8a + 4h) = -2 + 8a$$

$$14. f'(a) = \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{h \rightarrow 0} \frac{[(a+h)^4 - 5(a+h)] - (a^4 - 5a)}{h}$$

$$= \lim_{h \rightarrow 0} \frac{(a^4 + 4a^3h + 6a^2h^2 + 4ah^3 + h^4 - 5a - 5h) - (a^4 - 5a)}{h}$$

$$= \lim_{h \rightarrow 0} \frac{4a^3h + 6a^2h^2 + 4ah^3 + h^4 - 5h}{h} = \lim_{h \rightarrow 0} \frac{h(4a^3 + 6a^2h + 4ah^2 + h^3 - 5)}{h}$$

$$= \lim_{h \rightarrow 0} (4a^3 + 6a^2h + 4ah^2 + h^3 - 5) = 4a^3 - 5$$

15. Use Definition 2 with $f(t) = (2t+1)/(t+3)$.

$$f'(a) = \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{h \rightarrow 0} \frac{\frac{2(a+h)+1}{(a+h)+3} - \frac{2a+1}{a+3}}{h}$$

$$= \lim_{h \rightarrow 0} \frac{(2a+2h+1)(a+3) - (2a+1)(a+h+3)}{h(a+h+3)(a+3)}$$

$$= \lim_{h \rightarrow 0} \frac{(2a^2 + 6a + 2ah + 6h + a + 3) - (2a^2 + 2ah + 6a + a + h + 3)}{h(a+h+3)(a+3)}$$

$$= \lim_{h \rightarrow 0} \frac{5h}{h(a+h+3)(a+3)} = \lim_{h \rightarrow 0} \frac{5}{(a+h+3)(a+3)} = \frac{5}{(a+3)^2}$$

$$\begin{aligned}
 16. f'(a) &= \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{h \rightarrow 0} \frac{\frac{(a+h)^2 + 1}{(a+h) - 2} - \frac{a^2 + 1}{a - 2}}{h} \\
 &= \lim_{h \rightarrow 0} \frac{(a^2 + 2ah + h^2 + 1)(a - 2) - (a^2 + 1)(a + h - 2)}{h(a + h - 2)(a - 2)} \\
 &= \lim_{h \rightarrow 0} \frac{(a^3 - 2a^2 + 2a^2h - 4ah + ah^2 - 2h^2 + a - 2) - (a^3 + a^2h - 2a^2 + a + h - 2)}{h(a + h - 2)(a - 2)} \\
 &= \lim_{h \rightarrow 0} \frac{a^2h - 4ah + ah^2 - 2h^2 - h}{h(a + h - 2)(a - 2)} = \lim_{h \rightarrow 0} \frac{h(a^2 - 4a + ah - 2h - 1)}{h(a + h - 2)(a - 2)} \\
 &= \lim_{h \rightarrow 0} \frac{a^2 - 4a + ah - 2h - 1}{(a + h - 2)(a - 2)} = \frac{a^2 - 4a - 1}{(a - 2)^2}
 \end{aligned}$$

17. Use Definition 2 with $f(x) = 1/\sqrt{x+2}$.

$$\begin{aligned}
 f'(a) &= \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{h \rightarrow 0} \frac{\frac{1}{\sqrt{(a+h)+2}} - \frac{1}{\sqrt{a+2}}}{h} \\
 &= \lim_{h \rightarrow 0} \frac{\frac{\sqrt{a+2} - \sqrt{a+h+2}}{\sqrt{a+h+2}\sqrt{a+2}}}{h} = \lim_{h \rightarrow 0} \left[\frac{\sqrt{a+2} - \sqrt{a+h+2}}{h\sqrt{a+h+2}\sqrt{a+2}} \cdot \frac{\sqrt{a+2} + \sqrt{a+h+2}}{\sqrt{a+2} + \sqrt{a+h+2}} \right] \\
 &= \lim_{h \rightarrow 0} \frac{(a+2) - (a+h+2)}{h\sqrt{a+h+2}\sqrt{a+2}(\sqrt{a+2} + \sqrt{a+h+2})} \\
 &= \lim_{h \rightarrow 0} \frac{-h}{h\sqrt{a+h+2}\sqrt{a+2}(\sqrt{a+2} + \sqrt{a+h+2})} \\
 &= \lim_{h \rightarrow 0} \frac{-1}{\sqrt{a+h+2}\sqrt{a+2}(\sqrt{a+2} + \sqrt{a+h+2})} \\
 &= \frac{-1}{(\sqrt{a+2})^2(2\sqrt{a+2})} = -\frac{1}{2(a+2)^{3/2}}
 \end{aligned}$$

$$\begin{aligned}
 18. f'(a) &= \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{h \rightarrow 0} \frac{\sqrt{3(a+h)+1} - \sqrt{3a+1}}{h} \\
 &= \lim_{h \rightarrow 0} \frac{(\sqrt{3a+3h+1} - \sqrt{3a+1})(\sqrt{3a+3h+1} + \sqrt{3a+1})}{h(\sqrt{3a+3h+1} + \sqrt{3a+1})} \\
 &= \lim_{h \rightarrow 0} \frac{(3a+3h+1) - (3a+1)}{h(\sqrt{3a+3h+1} + \sqrt{3a+1})} = \lim_{h \rightarrow 0} \frac{3h}{h(\sqrt{3a+3h+1} + \sqrt{3a+1})} \\
 &= \lim_{h \rightarrow 0} \frac{3}{\sqrt{3a+3h+1} + \sqrt{3a+1}} = \frac{3}{2\sqrt{3a+1}}
 \end{aligned}$$

Note that the answers to Exercises 19–24 are not unique.

19. By Definition 2, $\lim_{h \rightarrow 0} \frac{(1+h)^{10} - 1}{h} = f'(1)$, where $f(x) = x^{10}$ and $a = 1$.

Or: By Definition 2, $\lim_{h \rightarrow 0} \frac{(1+h)^{10} - 1}{h} = f'(0)$, where $f(x) = (1+x)^{10}$ and $a = 0$.

20. By Definition 2, $\lim_{h \rightarrow 0} \frac{\sqrt[4]{16+h} - 2}{h} = f'(16)$, where $f(x) = \sqrt[4]{x}$ and $a = 16$.

Or: By Definition 2, $\lim_{h \rightarrow 0} \frac{\sqrt[4]{16+h} - 2}{h} = f'(0)$, where $f(x) = \sqrt[4]{16+x}$ and $a = 0$.

21. By Equation 3, $\lim_{x \rightarrow 5} \frac{2^x - 32}{x - 5} = f'(5)$, where $f(x) = 2^x$ and $a = 5$.

22. By Equation 3, $\lim_{x \rightarrow \pi/4} \frac{\tan x - 1}{x - \pi/4} = f'(\pi/4)$, where $f(x) = \tan x$ and $a = \pi/4$.

23. By Definition 2, $\lim_{h \rightarrow 0} \frac{\cos(\pi + h) + 1}{h} = f'(\pi)$, where $f(x) = \cos x$ and $a = \pi$.

Or: By Definition 2, $\lim_{h \rightarrow 0} \frac{\cos(\pi + h) + 1}{h} = f'(0)$, where $f(x) = \cos(\pi + x)$ and $a = 0$.

24. By Equation 3, $\lim_{t \rightarrow 1} \frac{t^4 + t - 2}{t - 1} = f'(1)$, where $f(t) = t^4 + t$ and $a = 1$.

25. $v(2) = f'(2) = \lim_{h \rightarrow 0} \frac{f(2+h) - f(2)}{h} = \lim_{h \rightarrow 0} \frac{[(2+h)^2 - 6(2+h) - 5] - [2^2 - 6(2) - 5]}{h}$
 $= \lim_{h \rightarrow 0} \frac{(4 + 4h + h^2 - 12 - 6h - 5) - (-13)}{h} = \lim_{h \rightarrow 0} \frac{h^2 - 2h}{h} = \lim_{h \rightarrow 0} (h - 2) = -2 \text{ m/s}$

26. $v(2) = f'(2) = \lim_{h \rightarrow 0} \frac{f(2+h) - f(2)}{h}$
 $= \lim_{h \rightarrow 0} \frac{[2(2+h)^3 - (2+h) + 1] - [2(2)^3 - 2 + 1]}{h}$
 $= \lim_{h \rightarrow 0} \frac{(2h^3 + 12h^2 + 24h + 16 - 2 - h + 1) - 15}{h}$
 $= \lim_{h \rightarrow 0} \frac{2h^3 + 12h^2 + 23h}{h} = \lim_{h \rightarrow 0} (2h^2 + 12h + 23) = 23 \text{ m/s}$

27. (a) $f'(x)$ is the rate of change of the production cost with respect to the number of ounces of gold produced. Its units are dollars per ounce.

(b) After 800 ounces of gold have been produced, the rate at which the production cost is increasing is \$17/ounce. So the cost of producing the 800th (or 801st) ounce is about \$17.

(c) In the short term, the values of $f'(x)$ will decrease because more efficient use is made of start-up costs as x increases. But eventually $f'(x)$ might increase due to large-scale operations.

28. (a) $f'(5)$ is the rate of growth of the bacteria population when $t = 5$ hours. Its units are bacteria per hour.

(b) With unlimited space and nutrients, f' should increase as t increases; so $f'(5) < f'(10)$. If the supply of nutrients is limited, the growth rate slows down at some point in time, and the opposite may be true.

29. (a) $f'(v)$ is the rate at which the fuel consumption is changing with respect to the speed. Its units are (gal/h)/(mi/h).

(b) The fuel consumption is decreasing by 0.05 (gal/h)/(mi/h) as the car's speed reaches 20 mi/h. So if you increase your speed to 21 mi/h, you could expect to decrease your fuel consumption by about 0.05 (gal/h)/(mi/h).

30. (a) $f'(8)$ is the rate of change of the quantity of coffee sold with respect to the price per pound when the price is \$8 per pound. The units for $f'(8)$ are pounds/(dollars/pound).
 (b) $f'(8)$ is negative since the quantity of coffee sold will decrease as the price charged for it increases. People are generally less willing to buy a product when its price increases.

31. $T'(10)$ is the rate at which the temperature is changing at 10:00 A.M. To estimate the value of $T'(10)$, we will average the difference quotients obtained using the times $t = 8$ and $t = 12$. Let

$$A = \frac{T(8) - T(10)}{8 - 10} = \frac{72 - 81}{-2} = 4.5 \text{ and } B = \frac{T(12) - T(10)}{12 - 10} = \frac{88 - 81}{2} = 3.5. \text{ Then}$$

$$T'(10) = \lim_{t \rightarrow 10} \frac{T(t) - T(10)}{t - 10} \approx \frac{A + B}{2} = \frac{4.5 + 3.5}{2} = 4^\circ\text{F/h.}$$

32. **For 1910:** We will average the difference quotients obtained using the years 1900 and 1920.

$$\text{Let } A = \frac{E(1900) - E(1910)}{1900 - 1910} = \frac{48.3 - 51.1}{-10} = 0.28 \text{ and}$$

$$B = \frac{E(1920) - E(1910)}{1920 - 1910} = \frac{55.2 - 51.1}{10} = 0.41. \text{ Then}$$

$$E'(1910) = \lim_{t \rightarrow 1910} \frac{E(t) - E(1910)}{t - 1910} \approx \frac{A + B}{2} = 0.345. \text{ This means that life expectancy at birth was increasing at about } 0.345 \text{ year/year in } 1910.$$

For 1950: Using data for 1940 and 1960 in a similar fashion, we obtain $E'(1950) \approx [0.31 + 0.10]/2 = 0.205$. So life expectancy at birth was increasing at about 0.205 year/year in 1950.

33. (a) $S'(T)$ is the rate at which the oxygen solubility changes with respect to the water temperature. Its units are (mg/L)/°C.
 (b) For $T = 16^\circ\text{C}$, it appears that the tangent line to the curve goes through the points (0, 14) and (32, 6). So $S'(16) \approx \frac{6 - 14}{32 - 0} = -\frac{8}{32} = -0.25 \text{ (mg/L)/}^\circ\text{C}$. This means that as the temperature increases past 16°C , the oxygen solubility is decreasing at a rate of 0.25 (mg/L)/°C.
34. (a) $S'(T)$ is the rate of change of the maximum sustainable speed of Coho salmon with respect to the temperature. Its units are (cm/s)/°C.
 (b) For $T = 15^\circ\text{C}$, it appears the tangent line to the curve goes through the points (10, 25) and (20, 32). So $S'(15) \approx \frac{32 - 25}{20 - 10} = 0.7 \text{ (cm/s)/}^\circ\text{C}$. This tells us that at $T = 15^\circ\text{C}$, the maximum sustainable speed of Coho salmon is changing at a rate of 0.7 (cm/s)/°C. In a similar fashion for $T = 25^\circ\text{C}$, we can use the points (20, 35) and (25, 25) to obtain $S'(25) \approx \frac{25 - 35}{25 - 20} = -2 \text{ (cm/s)/}^\circ\text{C}$. As it gets warmer than 20°C , the maximum sustainable speed decreases rapidly.

35. Since $f(x) = x \sin(1/x)$ when $x \neq 0$ and $f(0) = 0$, we have

$$f'(0) = \lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h} = \lim_{h \rightarrow 0} \frac{h \sin(1/h) - 0}{h} = \lim_{h \rightarrow 0} \sin(1/h). \text{ This limit does not exist since } \sin(1/h)$$

takes the values -1 and 1 on any interval containing 0 . (Compare with Example 4 in Section 2.2.)

36. Since $f(x) = x^2 \sin(1/x)$ when $x \neq 0$ and $f(0) = 0$, we have

$$f'(0) = \lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h} = \lim_{h \rightarrow 0} \frac{h^2 \sin(1/h) - 0}{h} = \lim_{h \rightarrow 0} h \sin(1/h).$$

Since $-1 \leq \sin \frac{1}{h} \leq 1$, we have $-|h| \leq |h| \sin \frac{1}{h} \leq |h| \Rightarrow -|h| \leq h \sin \frac{1}{h} \leq |h|$. Because $\lim_{h \rightarrow 0} (-|h|) = 0$ and $\lim_{h \rightarrow 0} |h| = 0$, we know that $\lim_{h \rightarrow 0} \left(h \sin \frac{1}{h} \right) = 0$ by the Squeeze Theorem. Thus, $f'(0) = 0$.

3.2 The Derivative as a Function

1. *Note:* Your answers may vary depending on your estimates. By estimating the slopes of tangent lines on the graph of f , it appears that

- | | |
|------------------------|--------------------------|
| (a) $f'(1) \approx -2$ | (b) $f'(2) \approx 0.8$ |
| (c) $f'(3) \approx -1$ | (d) $f'(4) \approx -0.5$ |

2. *Note:* Your answers may vary depending on your estimates. By estimating the slopes of tangent lines on the graph of f , it appears that

- | | |
|-------------------------|--------------------------|
| (a) $f'(0) \approx -3$ | (b) $f'(1) \approx 0$ |
| (c) $f'(2) \approx 1.5$ | (d) $f'(3) \approx 2$ |
| (e) $f'(4) \approx 0$ | (f) $f'(5) \approx -1.2$ |

3. It appears that f is an odd function, so f' will be an even function—that is, $f'(-a) = f'(a)$.

- | | |
|--------------------------|------------------------|
| (a) $f'(-3) \approx 1.5$ | (b) $f'(-2) \approx 1$ |
| (c) $f'(-1) \approx 0$ | (d) $f'(0) \approx -4$ |
| (e) $f'(1) \approx 0$ | (f) $f'(2) \approx 1$ |
| (g) $f'(3) \approx 1.5$ | |

4. (a)' = II, since from left to right, the slopes of the tangents to graph (a) start out negative, become 0, then positive, then 0, then negative again. The actual function values in graph II follow the same pattern.
- (b)' = IV, since from left to right, the slopes of the tangents to graph (b) start out at a fixed positive quantity, then suddenly become negative, then positive again. The discontinuities in graph IV indicate sudden changes in the slopes of the tangents.
- (c)' = I, since the slopes of the tangents to graph (c) are negative for $x < 0$ and positive for $x > 0$, as are the function values of graph I.
- (d)' = III, since from left to right, the slopes of the tangents to graph (d) are positive, then 0, then negative, then 0, then positive, then 0, then negative again, and the function values in graph III follow the same pattern.

Hints for Exercises 5–13: First plot x -intercepts on the graph of f' for any horizontal tangents on the graph of f . Look for any corners on the graph of f — there will be a discontinuity on the graph of f' . On any interval where f has a tangent with positive (or negative) slope, the graph of f' will be positive (or negative). If the graph of the function is linear, the graph of f' will be a horizontal line.

8.

9.

10.

11.

12.

13.

14. The slopes of the tangent lines on the graph of $y = P(t)$ are always positive, so the y -values of $y = P'(t)$ are always positive. These values start out relatively small and keep increasing, reaching a maximum at about $t = 6$. Then the y -values of $y = P'(t)$ decrease and get close to zero. The graph of P' tells us that the yeast culture grows most rapidly after 6 hours and then the growth rate declines.

15. It appears that there are horizontal tangents on the graph of M for $t = 1963$ and $t = 1971$. Thus, there are zeros for those values of t on the graph of M' . The derivative is negative for the years 1963 to 1971.

16. See Figure 1 in Section 3.5.

17. (a) By zooming in, we estimate that $f'(0) = 0$, $f'(\frac{1}{2}) = 1$, $f'(1) = 2$, and $f'(2) = 4$.

- (b) By symmetry, $f'(-x) = -f'(x)$. So $f'(-\frac{1}{2}) = -1$, $f'(-1) = -2$, and $f'(-2) = -4$.

- (c) It appears that $f'(x)$ is twice the value of x , so we guess that $f'(x) = 2x$.

$$\begin{aligned} \text{(d) } f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{(x+h)^2 - x^2}{h} \\ &= \lim_{h \rightarrow 0} \frac{(x^2 + 2hx + h^2) - x^2}{h} = \lim_{h \rightarrow 0} \frac{2hx + h^2}{h} = \lim_{h \rightarrow 0} \frac{h(2x + h)}{h} = \lim_{h \rightarrow 0} (2x + h) = 2x \end{aligned}$$

18. (a) By zooming in, we estimate that $f'(0) = 0$, $f'(\frac{1}{2}) \approx 0.75$, $f'(1) \approx 3$, $f'(2) \approx 12$, and $f'(3) \approx 27$.

- (b) By symmetry, $f'(-x) = f'(x)$. So $f'(-\frac{1}{2}) \approx 0.75$, $f'(-1) \approx 3$, $f'(-2) \approx 12$, and $f'(-3) \approx 27$.

- (d) Since $f'(0) = 0$, it appears that f' may have the form $f'(x) = ax^2$. Using $f'(1) = 3$, we have $a = 3$, so $f'(x) = 3x^2$.

$$\begin{aligned} \text{(e) } f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{(x+h)^3 - x^3}{h} = \lim_{h \rightarrow 0} \frac{(x^3 + 3x^2h + 3xh^2 + h^3) - x^3}{h} \\ &= \lim_{h \rightarrow 0} \frac{3x^2h + 3xh^2 + h^3}{h} = \lim_{h \rightarrow 0} \frac{h(3x^2 + 3xh + h^2)}{h} = \lim_{h \rightarrow 0} (3x^2 + 3xh + h^2) = 3x^2 \end{aligned}$$

19. $f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{37 - 37}{h} = \lim_{h \rightarrow 0} \frac{0}{h} = \lim_{h \rightarrow 0} 0 = 0$
Domain of $f = \text{domain of } f' = \mathbb{R}$.

 \end{aligned}$$

Domain of $g = [-\frac{1}{2}, \infty)$, domain of $g' = (-\frac{1}{2}, \infty)$.

$$\begin{aligned}
 26. f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{\frac{3+(x+h)}{1-3(x+h)} - \frac{3+x}{1-3x}}{h} \\
 &= \lim_{h \rightarrow 0} \frac{(3+x+h)(1-3x) - (3+x)(1-3x-3h)}{h(1-3x-3h)(1-3x)} \\
 &= \lim_{h \rightarrow 0} \frac{(3-9x+x-3x^2+h-3hx) - (3-9x-9h+x-3x^2-3hx)}{h(1-3x-3h)(1-3x)} \\
 &= \lim_{h \rightarrow 0} \frac{10h}{h(1-3x-3h)(1-3x)} = \lim_{h \rightarrow 0} \frac{10}{(1-3x-3h)(1-3x)} = \frac{10}{(1-3x)^2}
 \end{aligned}$$

Domain of f = domain of $f' = (-\infty, \frac{1}{3}) \cup (\frac{1}{3}, \infty)$.

$$\begin{aligned}
 27. G'(t) &= \lim_{h \rightarrow 0} \frac{G(t+h) - G(t)}{h} = \lim_{h \rightarrow 0} \frac{\frac{4(t+h)}{(t+h)+1} - \frac{4t}{t+1}}{h} = \lim_{h \rightarrow 0} \frac{\frac{4(t+h)(t+1) - 4t(t+h+1)}{(t+h+1)(t+1)}}{h} \\
 &= \lim_{h \rightarrow 0} \frac{(4t^2 + 4ht + 4t + 4h) - (4t^2 + 4ht + 4t)}{h(t+h+1)(t+1)} \\
 &= \lim_{h \rightarrow 0} \frac{4h}{h(t+h+1)(t+1)} = \lim_{h \rightarrow 0} \frac{4}{(t+h+1)(t+1)} = \frac{4}{(t+1)^2}
 \end{aligned}$$

Domain of G = domain of $G' = (-\infty, -1) \cup (-1, \infty)$.

$$\begin{aligned}
 28. g'(x) &= \lim_{h \rightarrow 0} \frac{g(x+h) - g(x)}{h} = \lim_{h \rightarrow 0} \frac{\frac{1}{(x+h)^2} - \frac{1}{x^2}}{h} = \lim_{h \rightarrow 0} \frac{x^2 - (x+h)^2}{h(x+h)^2 x^2} \\
 &= \lim_{h \rightarrow 0} \frac{x^2 - (x^2 + 2xh + h^2)}{h} = \lim_{h \rightarrow 0} \frac{-2xh - h^2}{h(x+h)^2 x^2} = \lim_{h \rightarrow 0} \frac{-2x - h}{(x+h)^2 x^2} = \frac{-2x}{x^4} \\
 &= -2x^{-3}
 \end{aligned}$$

Domain of g = domain of $g' = \{x \mid x \neq 0\}$.

$$\begin{aligned}
 29. f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{(x+h)^4 - x^4}{h} = \lim_{h \rightarrow 0} \frac{(x^4 + 4x^3h + 6x^2h^2 + 4xh^3 + h^4) - x^4}{h} \\
 &= \lim_{h \rightarrow 0} \frac{4x^3h + 6x^2h^2 + 4xh^3 + h^4}{h} = \lim_{h \rightarrow 0} (4x^3 + 6x^2h + 4xh^2 + h^3) = 4x^3
 \end{aligned}$$

Domain of f = domain of $f' = \mathbb{R}$.

30. (a)

(b) Note that the third graph in part (a) has small negative values for its slope, f' ; but as $x \rightarrow 6^-$, $f' \rightarrow -\infty$.
See the graph in part (d).

$$\begin{aligned}
 \text{(c) } f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{\sqrt{6 - (x+h)} - \sqrt{6-x}}{h} \left[\frac{\sqrt{6 - (x+h)} + \sqrt{6-x}}{\sqrt{6 - (x+h)} + \sqrt{6-x}} \right] \\
 &= \lim_{h \rightarrow 0} \frac{[6 - (x+h)] - (6-x)}{h [\sqrt{6 - (x+h)} + \sqrt{6-x}]} = \lim_{h \rightarrow 0} \frac{-h}{h(\sqrt{6-x-h} + \sqrt{6-x})} \\
 &= \lim_{h \rightarrow 0} \frac{-1}{\sqrt{6-x-h} + \sqrt{6-x}} = \frac{-1}{2\sqrt{6-x}}
 \end{aligned}$$

Domain of $f = (-\infty, 6]$, domain of $f' = (-\infty, 6)$.

$$\begin{aligned}
 \text{31. (a) } f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{\left[x+h - \left(\frac{2}{x+h} \right) \right] - \left[x - \left(\frac{2}{x} \right) \right]}{h} \\
 &= \lim_{h \rightarrow 0} \frac{\left[h - \frac{2}{(x+h)} + \frac{2}{x} \right]}{h} = \lim_{h \rightarrow 0} \left[1 + \frac{-2x + 2(x+h)}{hx(x+h)} \right] = \lim_{h \rightarrow 0} \left[1 + \frac{2h}{hx(x+h)} \right] \\
 &= \lim_{h \rightarrow 0} \left[1 + \frac{2}{x(x+h)} \right] = 1 + \frac{2}{x^2}
 \end{aligned}$$

(b) Notice that when f has steep tangent lines, $f'(x)$ is very large.

When f is flatter, $f'(x)$ is smaller.

$$\begin{aligned}
 \text{32. (a) } f'(t) &= \lim_{h \rightarrow 0} \frac{f(t+h) - f(t)}{h} = \lim_{h \rightarrow 0} \frac{\frac{6}{1 + (t+h)^2} - \frac{6}{1+t^2}}{h} = \lim_{h \rightarrow 0} \frac{6 + 6t^2 - 6 - 6(t+h)^2}{h[1 + (t+h)^2](1+t^2)} \\
 &= \lim_{h \rightarrow 0} \frac{-12th - 6h^2}{h[1 + (t+h)^2](1+t^2)} = \lim_{h \rightarrow 0} \frac{-12t - 6h}{[1 + (t+h)^2](1+t^2)} = \frac{-12t}{(1+t^2)^2}
 \end{aligned}$$

(b) Notice that f has a horizontal tangent when $t = 0$. This corresponds

to $f'(0) = 0$. f' is positive when f is increasing and negative when f is decreasing.

33. (a) $U'(t)$ is the rate at which the unemployment rate is changing with respect to time. Its units are percent per year.

(b) To find $U'(t)$, we use $\lim_{h \rightarrow 0} \frac{U(t+h) - U(t)}{h} \approx \frac{U(t+h) - U(t)}{h}$ for small values of h .

For 1991: $U'(1991) = \frac{U(1992) - U(1991)}{1992 - 1991} = \frac{7.5 - 6.8}{1} = 0.70$

For 1992: We estimate $U'(1992)$ by using $h = -1$ and $h = 1$, and then average the two results to obtain a final estimate.

$h = -1 \Rightarrow U'(1992) \approx \frac{U(1991) - U(1992)}{1991 - 1992} = \frac{6.8 - 7.5}{-1} = 0.70;$

$h = 1 \Rightarrow U'(1992) \approx \frac{U(1993) - U(1992)}{1993 - 1992} = \frac{6.9 - 7.5}{1} = -0.60.$

So we estimate that $U'(1992) \approx \frac{1}{2}[0.70 + (-0.60)] = 0.05$.

t	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000
$U'(t)$	0.70	0.05	-0.70	-0.65	-0.35	-0.35	-0.45	-0.35	-0.25	-0.20

34. (a) $P'(t)$ is the rate at which the percentage of Americans under the age of 18 is changing with respect to time. Its units are percent per year (%/yr).

(b) To find $P'(t)$, we use $\lim_{h \rightarrow 0} \frac{P(t+h) - P(t)}{h} \approx \frac{P(t+h) - P(t)}{h}$ for small values of h .

For 1950: $P'(1950) = \frac{P(1960) - P(1950)}{1960 - 1950} = \frac{35.7 - 31.1}{10} = 0.46$

For 1960: We estimate $P'(1960)$ by using $h = -10$ and $h = 10$, and then average the two results to obtain a final estimate.

$h = -10 \Rightarrow P'(1960) \approx \frac{P(1950) - P(1960)}{1950 - 1960} = \frac{31.1 - 35.7}{-10} = 0.46$

$h = 10 \Rightarrow P'(1960) \approx \frac{P(1970) - P(1960)}{1970 - 1960} = \frac{34.0 - 35.7}{10} = -0.17$

So we estimate that $P'(1960) \approx \frac{1}{2}[0.46 + (-0.17)] = 0.145$.

t	1950	1960	1970	1980	1990	2000
$P'(t)$	0.460	0.145	-0.385	-0.415	-0.115	0.000

(c)

- (d) We could get more accurate values for $P'(t)$ by obtaining data for the mid-decade years 1955, 1965, 1975, 1985, and 1995.
35. f is not differentiable at $x = -1$ or at $x = 11$ because the graph has vertical tangents at those points; at $x = 4$, because there is a discontinuity there; and at $x = 8$, because the graph has a corner there.
36. (a) g is discontinuous at $x = -2$ (a removable discontinuity), at $x = 0$ (g is not defined there), and at $x = 5$ (a jump discontinuity).
- (b) g is not differentiable at the points mentioned in part (a) (by Theorem 4), nor is it differentiable at $x = -1$ (corner), $x = 2$ (vertical tangent), or $x = 4$ (vertical tangent).

37. As we zoom in toward $(-1, 0)$, the curve appears more and more like a straight line, so $f(x) = x + \sqrt{|x|}$ is differentiable at $x = -1$. But no matter how much we zoom in toward the origin, the curve doesn't straighten out—we can't eliminate the sharp point (a cusp). So f is not differentiable at $x = 0$.

38. As we zoom in toward $(0, 1)$, the curve appears more and more like a straight line, so f is differentiable at $x = 0$. But no matter how much we zoom in toward $(1, 0)$ or $(-1, 0)$, the curve doesn't straighten out—we can't eliminate the sharp point (a cusp). So f is not differentiable at $x = \pm 1$.

39. (a) Note that we have factored $x - a$ as the difference of two cubes in the third step.

$$\begin{aligned} f'(a) &= \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} = \lim_{x \rightarrow a} \frac{x^{1/3} - a^{1/3}}{x - a} = \lim_{x \rightarrow a} \frac{x^{1/3} - a^{1/3}}{(x^{1/3} - a^{1/3})(x^{2/3} + x^{1/3}a^{1/3} + a^{2/3})} \\ &= \lim_{x \rightarrow a} \frac{1}{x^{2/3} + x^{1/3}a^{1/3} + a^{2/3}} = \frac{1}{3a^{2/3}} \text{ or } \frac{1}{3}a^{-2/3} \end{aligned}$$

- (b) $f'(0) = \lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h} = \lim_{h \rightarrow 0} \frac{\sqrt[3]{h} - 0}{h} = \lim_{h \rightarrow 0} \frac{1}{h^{2/3}}$. This function increases without bound, so the limit does not exist, and therefore $f'(0)$ does not exist.

- (c) $\lim_{x \rightarrow 0} |f'(x)| = \lim_{x \rightarrow 0} \frac{1}{3x^{2/3}} = \infty$ and f is continuous at $x = 0$ (root function), so f has a vertical tangent at $x = 0$.

40. (a) $g'(0) = \lim_{x \rightarrow 0} \frac{g(x) - g(0)}{x - 0} = \lim_{x \rightarrow 0} \frac{x^{2/3} - 0}{x} = \lim_{x \rightarrow 0} \frac{1}{x^{1/3}}$, which does not exist.

$$\begin{aligned} \text{(b) } g'(a) &= \lim_{x \rightarrow a} \frac{g(x) - g(a)}{x - a} = \lim_{x \rightarrow a} \frac{x^{2/3} - a^{2/3}}{x - a} = \lim_{x \rightarrow a} \frac{(x^{1/3} - a^{1/3})(x^{1/3} + a^{1/3})}{(x^{1/3} - a^{1/3})(x^{2/3} + x^{1/3}a^{1/3} + a^{2/3})} \\ &= \lim_{x \rightarrow a} \frac{x^{1/3} + a^{1/3}}{x^{2/3} + x^{1/3}a^{1/3} + a^{2/3}} = \frac{2a^{1/3}}{3a^{2/3}} = \frac{2}{3a^{1/3}} \text{ or } \frac{2}{3}a^{-1/3} \end{aligned}$$

(c) $g(x) = x^{2/3}$ is continuous at $x = 0$ and

$$\lim_{x \rightarrow 0} |g'(x)| = \lim_{x \rightarrow 0} \frac{2}{3|x|^{1/3}} = \infty. \text{ This shows that}$$

g has a vertical tangent line at $x = 0$.

$$41. f(x) = |x - 6| = \begin{cases} -(x - 6) & \text{if } x < 6 \\ x - 6 & \text{if } x \geq 6 \end{cases} = \begin{cases} 6 - x & \text{if } x < 6 \\ x - 6 & \text{if } x \geq 6 \end{cases}$$

$$\lim_{x \rightarrow 6^+} \frac{f(x) - f(6)}{x - 6} = \lim_{x \rightarrow 6^+} \frac{|x - 6| - 0}{x - 6} = \lim_{x \rightarrow 6^+} \frac{x - 6}{x - 6} = \lim_{x \rightarrow 6^+} 1 = 1.$$

$$\begin{aligned} \text{But } \lim_{x \rightarrow 6^-} \frac{f(x) - f(6)}{x - 6} &= \lim_{x \rightarrow 6^-} \frac{|x - 6| - 0}{x - 6} = \lim_{x \rightarrow 6^-} \frac{6 - x}{x - 6} \\ &= \lim_{x \rightarrow 6^-} (-1) = -1 \end{aligned}$$

$$\text{So } f'(6) = \lim_{x \rightarrow 6} \frac{f(x) - f(6)}{x - 6} \text{ does not exist. However, } f'(x) = \begin{cases} -1 & \text{if } x < 6 \\ 1 & \text{if } x > 6 \end{cases}$$

Another way of writing the answer is $f'(x) = \frac{x - 6}{|x - 6|}$.

42. $f(x) = \llbracket x \rrbracket$ is not continuous at any integer n , so f is not differentiable at n by the contrapositive of Theorem 4. If a is not an integer, then f is constant on an open interval containing a , so $f'(a) = 0$. Thus, $f'(x) = 0$, x not an integer.

$$43. (a) f(x) = x|x| = \begin{cases} x^2 & \text{if } x \geq 0 \\ -x^2 & \text{if } x < 0 \end{cases}$$

(b) Since $f(x) = x^2$ for $x \geq 0$, we have $f'(x) = 2x$ for $x > 0$.

[See Exercise 3.2.17(d).] Similarly, since $f(x) = -x^2$ for $x < 0$, we have $f'(x) = -2x$ for $x < 0$. At $x = 0$, we have

$$f'(0) = \lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0} \frac{x|x|}{x} = \lim_{x \rightarrow 0} |x| = 0.$$

So f is differentiable at 0. Thus, f is differentiable for all x .

$$(c) \text{ From part (b), we have } f'(x) = \begin{cases} 2x & \text{if } x \geq 0 \\ -2x & \text{if } x < 0 \end{cases} = 2|x|.$$

44. (a) $f'_-(4) = \lim_{h \rightarrow 0^-} \frac{f(4+h) - f(4)}{h} = \lim_{h \rightarrow 0^-} \frac{5 - (4+h) - 1}{h} = \lim_{h \rightarrow 0^-} \frac{-h}{h} = -1$ and

$$f'_+(4) = \lim_{h \rightarrow 0^+} \frac{f(4+h) - f(4)}{h} = \lim_{h \rightarrow 0^+} \frac{\frac{1}{5 - (4+h)} - 1}{h} = \lim_{h \rightarrow 0^+} \frac{1 - (1-h)}{h(1-h)} = \lim_{h \rightarrow 0^+} \frac{1}{1-h} = 1.$$

(c)
$$f(x) = \begin{cases} 0 & \text{if } x \leq 0 \\ 5 - x & \text{if } 0 < x < 4 \\ 1/(5 - x) & \text{if } x \geq 4 \end{cases}$$

These expressions show that f is continuous on the intervals $(-\infty, 0)$, $(0, 4)$, $(4, 5)$ and $(5, \infty)$. Since

$$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} (5 - x) = 5 \neq 0 = \lim_{x \rightarrow 0^-} f(x), \quad \lim_{x \rightarrow 0^-} f(x)$$

does not exist, so f is discontinuous (and therefore not differentiable) at 0.

At 4 we have $\lim_{x \rightarrow 4^-} f(x) = \lim_{x \rightarrow 4^-} (5 - x) = 1$ and $\lim_{x \rightarrow 4^+} f(x) = \lim_{x \rightarrow 4^+} \frac{1}{5 - x} = 1$, so $\lim_{x \rightarrow 4} f(x) = 1 = f(4)$ and f is continuous at 4. Since $f(5)$ is not defined, f is discontinuous at 5.

(d) From (a), f is not differentiable at 4 since $f'_-(4) \neq f'_+(4)$, and from (c), f is not differentiable at 0 or 5.

45. (a) If f is even, then

$$\begin{aligned} f'(-x) &= \lim_{h \rightarrow 0} \frac{f(-x+h) - f(-x)}{h} = \lim_{h \rightarrow 0} \frac{f[-(x-h)] - f(-x)}{h} = \lim_{h \rightarrow 0} \frac{f(x-h) - f(x)}{h} \\ &= - \lim_{h \rightarrow 0} \frac{f(x-h) - f(x)}{-h} \quad [\text{let } \Delta x = -h] = - \lim_{\Delta x \rightarrow 0} \frac{f(x+\Delta x) - f(x)}{\Delta x} = -f'(x) \end{aligned}$$

Therefore, f' is odd.

(b) If f is odd, then

$$\begin{aligned} f'(-x) &= \lim_{h \rightarrow 0} \frac{f(-x+h) - f(-x)}{h} = \lim_{h \rightarrow 0} \frac{f[-(x-h)] - f(-x)}{h} = \lim_{h \rightarrow 0} \frac{-f(x-h) + f(x)}{h} \\ &= \lim_{h \rightarrow 0} \frac{f(x-h) - f(x)}{-h} \quad [\text{let } \Delta x = -h] = \lim_{\Delta x \rightarrow 0} \frac{f(x+\Delta x) - f(x)}{\Delta x} = f'(x) \end{aligned}$$

Therefore, f' is even.

46. (a)

(c)

(b) The initial temperature of the water is close to room temperature because of the water that was in the pipes. When the water from the hot water tank starts coming out, dT/dt is large and positive as T increases to the temperature of the water in the tank. In the next phase, $dT/dt = 0$ as the water comes out at a constant, high temperature. After some time, dT/dt becomes small and negative as the contents of the hot water tank are exhausted. Finally, when the hot water has run out, dT/dt is once again 0 as the water maintains its (cold) temperature.

47.

In the right triangle in the diagram, let Δy be the side opposite angle ϕ and Δx the side adjacent angle ϕ . Then the slope of the tangent line ℓ is $m = \Delta y / \Delta x = \tan \phi$. Note that $0 < \phi < \frac{\pi}{2}$. We know (see Exercise 17) that the derivative of $f(x) = x^2$ is $f'(x) = 2x$. So the slope of the tangent to the curve at the point $(1, 1)$ is 2. Thus, ϕ is the angle between 0 and $\frac{\pi}{2}$ whose tangent is 2; that is, $\phi = \tan^{-1} 2 \approx 63^\circ$.

3.3 Differentiation Formulas

1. $f(x) = 186.5$ is a constant function, so its derivative is 0, that is, $f'(x) = 0$.
2. $f(x) = \sqrt{30}$ is a constant function, so its derivative is 0, that is, $f'(x) = 0$.
3. $f(x) = 5x - 1 \Rightarrow f'(x) = 5 - 0 = 5$
4. $F(x) = -4x^{10} \Rightarrow F'(x) = -4(10x^{10-1}) = -40x^9$
5. $f(x) = x^2 + 3x - 4 \Rightarrow f'(x) = 2x^{2-1} + 3 - 0 = 2x + 3$
6. $g(x) = 5x^8 - 2x^5 + 6 \Rightarrow g'(x) = 5(8x^{8-1}) - 2(5x^{5-1}) + 0 = 40x^7 - 10x^4$
7. $f(t) = \frac{1}{4}(t^4 + 8) \Rightarrow f'(t) = \frac{1}{4}(t^4 + 8)' = \frac{1}{4}(4t^{4-1} + 0) = t^3$
8. $f(t) = \frac{1}{2}t^6 - 3t^4 + t \Rightarrow f'(t) = \frac{1}{2}(6t^5) - 3(4t^3) + 1 = 3t^5 - 12t^3 + 1$
9. $V(r) = \frac{4}{3}\pi r^3 \Rightarrow V'(r) = \frac{4}{3}\pi(3r^2) = 4\pi r^2$
10. $R(t) = 5t^{-3/5} \Rightarrow R'(t) = 5\left[-\frac{3}{5}t^{(-3/5)-1}\right] = -3t^{-8/5}$
11. $Y(t) = 6t^{-9} \Rightarrow Y'(t) = 6(-9)t^{-10} = -54t^{-10}$
12. $R(x) = \frac{\sqrt{10}}{x^7} = \sqrt{10}x^{-7} \Rightarrow R'(x) = -7\sqrt{10}x^{-8} = -\frac{7\sqrt{10}}{x^8}$
13. $F(x) = \left(\frac{1}{2}x\right)^5 = \left(\frac{1}{2}\right)^5 x^5 = \frac{1}{32}x^5 \Rightarrow F'(x) = \frac{1}{32}(5x^4) = \frac{5}{32}x^4$
14. $f(t) = \sqrt{t} - \frac{1}{\sqrt{t}} = t^{1/2} - t^{-1/2} \Rightarrow f'(t) = \frac{1}{2}t^{-1/2} - \left(-\frac{1}{2}t^{-3/2}\right) = \frac{1}{2\sqrt{t}} + \frac{1}{2t\sqrt{t}}$
15. $y = x^{-2/5} \Rightarrow y' = -\frac{2}{5}x^{(-2/5)-1} = -\frac{2}{5}x^{-7/5} = -\frac{2}{5x^{7/5}}$
16. $y = \sqrt[3]{x} = x^{1/3} \Rightarrow y' = \frac{1}{3}x^{-2/3} = \frac{1}{3x^{2/3}}$
17. $y = 4\pi^2 \Rightarrow y' = 0$ since $4\pi^2$ is a constant.
18. $g(u) = \sqrt{2}u + \sqrt{3}u = \sqrt{2}u + \sqrt{3}\sqrt{u} \Rightarrow g'(u) = \sqrt{2}(1) + \sqrt{3}\left(\frac{1}{2}u^{-1/2}\right) = \sqrt{2} + \sqrt{3}/(2\sqrt{u})$
19. $v = t^2 - \frac{1}{\sqrt[4]{t^3}} = t^2 - t^{-3/4} \Rightarrow v' = 2t - \left(-\frac{3}{4}\right)t^{-7/4} = 2t + \frac{3}{4t^{7/4}} = 2t + \frac{3}{4t\sqrt[4]{t^3}}$
20. $u = \sqrt[3]{t^2} + 2\sqrt{t^3} = t^{2/3} + 2t^{3/2} \Rightarrow u' = \frac{2}{3}t^{-1/3} + 2\left(\frac{3}{2}\right)t^{1/2} = \frac{2}{3\sqrt[3]{t}} + 3\sqrt{t}$
21. Product Rule: $y = (x^2 + 1)(x^3 + 1) \Rightarrow$
 $y' = (x^2 + 1)(3x^2) + (x^3 + 1)(2x) = 3x^4 + 3x^2 + 2x^4 + 2x = 5x^4 + 3x^2 + 2x$.
 Multiplying first: $y = (x^2 + 1)(x^3 + 1) = x^5 + x^3 + x^2 + 1 \Rightarrow y' = 5x^4 + 3x^2 + 2x$ (equivalent).

22. Quotient Rule: $F(x) = \frac{x - 3x\sqrt{x}}{\sqrt{x}} = \frac{x - 3x^{3/2}}{x^{1/2}} \Rightarrow$

$$F'(x) = \frac{x^{1/2} \left(1 - \frac{9}{2}x^{1/2}\right) - (x - 3x^{3/2}) \left(\frac{1}{2}x^{-1/2}\right)}{(x^{1/2})^2}$$

$$= \frac{x^{1/2} - \frac{9}{2}x - \frac{1}{2}x^{1/2} + \frac{3}{2}x}{x} = \frac{\frac{1}{2}x^{1/2} - 3x}{x} = \frac{1}{2}x^{-1/2} - 3$$

Simplifying first: $F(x) = \frac{x - 3x\sqrt{x}}{\sqrt{x}} = \sqrt{x} - 3x = x^{1/2} - 3x \Rightarrow F'(x) = \frac{1}{2}x^{-1/2} - 3$ (equivalent).

For this problem, simplifying first seems to be the better method.

The notations $\overset{\text{PR}}{\Rightarrow}$ and $\overset{\text{QR}}{\Rightarrow}$ indicate use of the Product and Quotient Rules, respectively.

23. $V(x) = (2x^3 + 3)(x^4 - 2x) \overset{\text{PR}}{\Rightarrow}$

$$V'(x) = (2x^3 + 3)(4x^3 - 2) + (x^4 - 2x)(6x^2) = (8x^6 + 8x^3 - 6) + (6x^6 - 12x^3) = 14x^6 - 4x^3 - 6$$

24. $Y(u) = (u^{-2} + u^{-3})(u^5 - 2u^2) \overset{\text{PR}}{\Rightarrow}$

$$Y'(u) = (u^{-2} + u^{-3})(5u^4 - 4u) + (u^5 - 2u^2)(-2u^{-3} - 3u^{-4})$$

$$= (5u^2 - 4u^{-1} + 5u - 4u^{-2}) + (-2u^2 - 3u + 4u^{-1} + 6u^{-2}) = 3u^2 + 2u + 2u^{-2}$$

25. $F(y) = \left(\frac{1}{y^2} - \frac{3}{y^4}\right)(y + 5y^3) = (y^{-2} - 3y^{-4})(y + 5y^3) \overset{\text{PR}}{\Rightarrow}$

$$F'(y) = (y^{-2} - 3y^{-4})(1 + 15y^2) + (y + 5y^3)(-2y^{-3} + 12y^{-5})$$

$$= (y^{-2} + 15 - 3y^{-4} - 45y^{-2}) + (-2y^{-2} + 12y^{-4} - 10 + 60y^{-2})$$

$$= 5 + 14y^{-2} + 9y^{-4} \text{ or } 5 + 14/y^2 + 9/y^4$$

26. $y = \sqrt{x}(x - 1) = x^{3/2} - x^{1/2} \Rightarrow y' = \frac{3}{2}x^{1/2} - \frac{1}{2}x^{-1/2} = \frac{1}{2}x^{-1/2}(3x - 1)$ [factor out $\frac{1}{2}x^{-1/2}$]

or $y' = \frac{3x - 1}{2\sqrt{x}}$.

27. $g(x) = \frac{3x - 1}{2x + 1} \overset{\text{QR}}{\Rightarrow} g'(x) = \frac{(2x + 1)(3) - (3x - 1)(2)}{(2x + 1)^2} = \frac{6x + 3 - 6x + 2}{(2x + 1)^2} = \frac{5}{(2x + 1)^2}$

28. $f(t) = \frac{2t}{4 + t^2} \overset{\text{QR}}{\Rightarrow} f'(t) = \frac{(4 + t^2)(2) - (2t)(2t)}{(4 + t^2)^2} = \frac{8 + 2t^2 - 4t^2}{(4 + t^2)^2} = \frac{8 - 2t^2}{(4 + t^2)^2}$

29. $y = \frac{t^2}{3t^2 - 2t + 1} \overset{\text{QR}}{\Rightarrow}$

$$y' = \frac{(3t^2 - 2t + 1)(2t) - t^2(6t - 2)}{(3t^2 - 2t + 1)^2} = \frac{2t[3t^2 - 2t + 1 - t(3t - 1)]}{(3t^2 - 2t + 1)^2}$$

$$= \frac{2t(3t^2 - 2t + 1 - 3t^2 + t)}{(3t^2 - 2t + 1)^2} = \frac{2t(1 - t)}{(3t^2 - 2t + 1)^2}$$

30. $y = \frac{t^3 + t}{t^4 - 2} \overset{\text{QR}}{\Rightarrow} y' = \frac{(t^4 - 2)(3t^2 + 1) - (t^3 + t)(4t^3)}{(t^4 - 2)^2} = \frac{(3t^6 + t^4 - 6t^2 - 2) - (4t^6 + 4t^4)}{(t^4 - 2)^2}$

$$= \frac{-t^6 - 3t^4 - 6t^2 - 2}{(t^4 - 2)^2} = -\frac{t^6 + 3t^4 + 6t^2 + 2}{(t^4 - 2)^2}$$

$$31. y = \frac{v^3 - 2v\sqrt{v}}{v} = v^2 - 2\sqrt{v} = v^2 - 2v^{1/2} \Rightarrow y' = 2v - 2\left(\frac{1}{2}\right)v^{-1/2} = 2v - v^{-1/2}.$$

We can change the form of the answer as follows: $2v - v^{-1/2} = 2v - \frac{1}{\sqrt{v}} = \frac{2v\sqrt{v} - 1}{\sqrt{v}} = \frac{2v^{3/2} - 1}{\sqrt{v}}$

$$32. y = \frac{\sqrt{x} - 1}{\sqrt{x} + 1} \Rightarrow$$

$$y' = \frac{(\sqrt{x} + 1)\left(\frac{1}{2\sqrt{x}}\right) - (\sqrt{x} - 1)\left(\frac{1}{2\sqrt{x}}\right)}{(\sqrt{x} + 1)^2} = \frac{\frac{1}{2} + \frac{1}{2\sqrt{x}} - \frac{1}{2} + \frac{1}{2\sqrt{x}}}{(\sqrt{x} + 1)^2} = \frac{1}{\sqrt{x}(\sqrt{x} + 1)^2}$$

$$33. y = \frac{1}{x^4 + x^2 + 1} \Rightarrow y' = \frac{(x^4 + x^2 + 1)(0) - 1(4x^3 + 2x)}{(x^4 + x^2 + 1)^2} = -\frac{2x(2x^2 + 1)}{(x^4 + x^2 + 1)^2}$$

$$34. y = x^2 + x + x^{-1} + x^{-2} \Rightarrow y' = 2x + 1 - x^{-2} - 2x^{-3}$$

$$35. y = ax^2 + bx + c \Rightarrow y' = 2ax + b$$

$$36. y = A + \frac{B}{x} + \frac{C}{x^2} = A + Bx^{-1} + Cx^{-2} \Rightarrow y' = -Bx^{-2} - 2Cx^{-3} = -\frac{B}{x^2} - 2\frac{C}{x^3}$$

$$37. y = \frac{r^2}{1 + \sqrt{r}} \Rightarrow$$

$$y' = \frac{(1 + \sqrt{r})(2r) - r^2\left(\frac{1}{2}r^{-1/2}\right)}{(1 + \sqrt{r})^2} = \frac{2r + 2r^{3/2} - \frac{1}{2}r^{3/2}}{(1 + \sqrt{r})^2} = \frac{2r + \frac{3}{2}r^{3/2}}{(1 + \sqrt{r})^2} = \frac{\frac{1}{2}r(4 + 3r^{1/2})}{(1 + \sqrt{r})^2} = \frac{r(4 + 3\sqrt{r})}{2(1 + \sqrt{r})^2}$$

$$38. y = \frac{cx}{1 + cx} \Rightarrow y' = \frac{(1 + cx)(c) - (cx)(c)}{(1 + cx)^2} = \frac{c + c^2x - c^2x}{(1 + cx)^2} = \frac{c}{(1 + cx)^2}$$

$$39. y = \sqrt[3]{t}(t^2 + t + t^{-1}) = t^{1/3}(t^2 + t + t^{-1}) = t^{7/3} + t^{4/3} + t^{-2/3} \Rightarrow$$

$$y' = \frac{7}{3}t^{4/3} + \frac{4}{3}t^{1/3} - \frac{2}{3}t^{-5/3} = \frac{1}{3}t^{-5/3}(7t^{9/3} + 4t^{6/3} - 2) = (7t^3 + 4t^2 - 2)/(3t^{5/3})$$

$$40. y = \frac{u^6 - 2u^3 + 5}{u^2} = u^4 - 2u + 5u^{-2} \Rightarrow$$

$$y' = 4u^3 - 2 - 10u^{-3} = 2u^{-3}(2u^6 - u^3 - 5) = 2(2u^6 - u^3 - 5)/u^3$$

$$41. f(x) = \frac{x}{x + c/x} \Rightarrow$$

$$f'(x) = \frac{(x + c/x)(1) - x(1 - c/x^2)}{\left(x + \frac{c}{x}\right)^2} = \frac{x + c/x - x + c/x}{\left(\frac{x^2 + c}{x}\right)^2} = \frac{2c/x}{\frac{(x^2 + c)^2}{x^2}} = \frac{2cx}{(x^2 + c)^2}$$

$$42. f(x) = \frac{ax + b}{cx + d} \Rightarrow f'(x) = \frac{(cx + d)(a) - (ax + b)(c)}{(cx + d)^2} = \frac{acx + ad - acx - bc}{(cx + d)^2} = \frac{ad - bc}{(cx + d)^2}$$

$$43. P(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_2 x^2 + a_1 x + a_0 \Rightarrow$$

$$P'(x) = na_n x^{n-1} + (n-1)a_{n-1} x^{n-2} + \cdots + 2a_2 x + a_1$$

$$44. f(x) = \frac{x}{x^2 - 1} \Rightarrow$$

$$f'(x) = \frac{(x^2 - 1)(1) - x(2x)}{(x^2 - 1)^2} = \frac{-x^2 - 1}{(x^2 - 1)^2} = -\frac{x^2 + 1}{(x^2 - 1)^2}$$

Notice that the slopes of all tangents to f are negative and $f'(x) < 0$ always.

$$45. f(x) = 3x^{15} - 5x^3 + 3 \Rightarrow f'(x) = 45x^{14} - 15x^2.$$

Notice that $f'(x) = 0$ when f has a horizontal tangent, f' is positive when f is increasing, and f' is negative when f is decreasing.

$$46. f(x) = x + 1/x = x + x^{-1} \Rightarrow f'(x) = 1 - x^{-2} = 1 - 1/x^2.$$

Notice that $f'(x) = 0$ when f has a horizontal tangent, f' is positive when f is increasing, and f' is negative when f is decreasing.

47. To graphically estimate the value of $f'(1)$ for $f(x) = 3x^2 - x^3$, we'll graph f in the viewing rectangle $[1 - 0.1, 1 + 0.1]$ by $[f(0.9), f(1.1)]$, as shown in the figure. [When assigning values to the window variables, it is convenient to use $Y_1(0.9)$ for $Y_{\min}$ and $Y_1(1.1)$ for $Y_{\max}$.] If we have sufficiently zoomed in on the graph of f , we should obtain a graph that looks like a diagonal line; if not, graph again with $1 - 0.01$ and $1 + 0.01$, etc.

Estimated value:

$$f'(1) \approx \frac{2.299 - 1.701}{1.1 - 0.9} = \frac{0.598}{0.2} = 2.99.$$

Exact value: $f(x) = 3x^2 - x^3 \Rightarrow f'(x) = 6x - 3x^2$,
so $f'(1) = 6 - 3 = 3$.

48. See the previous exercise. Since f is a decreasing function, assign $Y_1(3.9)$ to $Y_{\max}$ and $Y_1(4.1)$ to $Y_{\min}$.

Estimated value: $f'(4) \approx \frac{0.49386 - 0.50637}{4.1 - 3.9} = \frac{-0.01251}{0.2} = -0.06255$.

Exact value: $f(x) = x^{-1/2} \Rightarrow f'(x) = -\frac{1}{2}x^{-3/2}$, so $f'(4) = -\frac{1}{2}(4^{-3/2}) = -\frac{1}{2}(\frac{1}{8}) = -\frac{1}{16} = -0.0625$.

49. (a)

(b)

From the graph in part (a), it appears that f' is zero at $x_1 \approx -1.25$, $x_2 \approx 0.5$, and $x_3 \approx 3$. The slopes are negative (so f' is negative) on $(-\infty, x_1)$ and (x_2, x_3) . The slopes are positive (so f' is positive) on (x_1, x_2) and (x_3, ∞) .

(c) $f(x) = x^4 - 3x^3 - 6x^2 + 7x + 30 \Rightarrow$
 $f'(x) = 4x^3 - 9x^2 - 12x + 7$

50. (a)

(b)

From the graph in part (a), it appears that g' is zero at $x = 0$. The slopes are negative (so g' is negative) on $(-\infty, 0)$. The slopes are positive (so g' is positive) on $(0, \infty)$.

(c) $g(x) = \frac{x^2}{x^2 + 1} \Rightarrow$
 $g'(x) = \frac{(x^2 + 1)(2x) - x^2(2x)}{(x^2 + 1)^2} = \frac{2x}{(x^2 + 1)^2}$

51. $y = \frac{2x}{x+1} \Rightarrow y' = \frac{(x+1)(2) - (2x)(1)}{(x+1)^2} = \frac{2}{(x+1)^2}$. At $(1, 1)$, $y' = \frac{1}{2}$, and an equation of the tangent line is $y - 1 = \frac{1}{2}(x - 1)$, or $y = \frac{1}{2}x + \frac{1}{2}$.

52. $y = \frac{\sqrt{x}}{x+1} \Rightarrow y' = \frac{(x+1)\left(\frac{1}{2\sqrt{x}}\right) - \sqrt{x}(1)}{(x+1)^2} = \frac{(x+1) - (2x)}{2\sqrt{x}(x+1)^2} = \frac{1-x}{2\sqrt{x}(x+1)^2}$. At $(4, 0.4)$, $y' = \frac{-3}{100} = -0.03$, and an equation of the tangent line is $y - 0.4 = -0.03(x - 4)$, or $y = -0.03x + 0.52$.

53. $y = f(x) = x + \sqrt{x} \Rightarrow f'(x) = 1 + \frac{1}{2}x^{-1/2}$. So the slope of the tangent line at $(1, 2)$ is $f'(1) = 1 + \frac{1}{2}(1) = \frac{3}{2}$ and its equation is $y - 2 = \frac{3}{2}(x - 1)$ or $y = \frac{3}{2}x + \frac{1}{2}$.

54. $y = (1 + 2x)^2 = 1 + 4x + 4x^2 \Rightarrow y' = 4 + 8x$. At $(1, 9)$, $y' = 12$ and an equation of the tangent line is $y - 9 = 12(x - 1)$ or $y = 12x - 3$.

55. (a) $y = f(x) = \frac{1}{1+x^2} \Rightarrow$

$$f'(x) = \frac{(1+x^2)(0) - 1(2x)}{(1+x^2)^2} = \frac{-2x}{(1+x^2)^2}. \text{ So the slope of the}$$

tangent line at the point $(-1, \frac{1}{2})$ is $f'(-1) = \frac{2}{2^2} = \frac{1}{2}$ and its

equation is $y - \frac{1}{2} = \frac{1}{2}(x + 1)$ or $y = \frac{1}{2}x + 1$.

56. (a) $y = f(x) = \frac{x}{1+x^2} \Rightarrow$

$$f'(x) = \frac{(1+x^2)1 - x(2x)}{(1+x^2)^2} = \frac{1-x^2}{(1+x^2)^2}. \text{ So the slope of the}$$

tangent line at the point $(3, 0.3)$ is $f'(3) = \frac{-8}{100}$ and its equation is

$y - 0.3 = -0.08(x - 3)$ or $y = -0.08x + 0.54$.

57. We are given that $f(5) = 1$, $f'(5) = 6$, $g(5) = -3$, and $g'(5) = 2$.

(a) $(fg)'(5) = f(5)g'(5) + g(5)f'(5) = (1)(2) + (-3)(6) = 2 - 18 = -16$

(b) $\left(\frac{f}{g}\right)'(5) = \frac{g(5)f'(5) - f(5)g'(5)}{[g(5)]^2} = \frac{(-3)(6) - (1)(2)}{(-3)^2} = -\frac{20}{9}$

(c) $\left(\frac{g}{f}\right)'(5) = \frac{f(5)g'(5) - g(5)f'(5)}{[f(5)]^2} = \frac{(1)(2) - (-3)(6)}{(1)^2} = 20$

58. We are given that $f(3) = 4$, $g(3) = 2$, $f'(3) = -6$, and $g'(3) = 5$.

(a) $(f+g)'(3) = f'(3) + g'(3) = -6 + 5 = -1$

(b) $(fg)'(3) = f(3)g'(3) + g(3)f'(3) = (4)(5) + (2)(-6) = 20 - 12 = 8$

(c) $\left(\frac{f}{g}\right)'(3) = \frac{g(3)f'(3) - f(3)g'(3)}{[g(3)]^2} = \frac{(2)(-6) - (4)(5)}{(2)^2} = \frac{-32}{4} = -8$

(d) $\left(\frac{f}{f-g}\right)'(3) = \frac{[f(3) - g(3)]f'(3) - f(3)[f'(3) - g'(3)]}{[f(3) - g(3)]^2}$
 $= \frac{(4-2)(-6) - 4(-6-5)}{(4-2)^2} = \frac{-12+44}{2^2} = 8$

59. $f(x) = \sqrt{x}g(x) \Rightarrow f'(x) = \sqrt{x}g'(x) + g(x) \cdot \frac{1}{2}x^{-1/2}$, so

$$f'(4) = \sqrt{4}g'(4) + g(4) \cdot \frac{1}{2\sqrt{4}} = 2 \cdot 7 + 8 \cdot \frac{1}{4} = 16.$$

60. $\frac{d}{dx} \left[\frac{h(x)}{x} \right] = \frac{xh'(x) - h(x) \cdot 1}{x^2} \Rightarrow \frac{d}{dx} \left[\frac{h(x)}{x} \right]_{x=2} = \frac{2h'(2) - h(2)}{2^2} = \frac{2(-3) - (4)}{4} = \frac{-10}{4} = -2.5$

61. (a) From the graphs of f and g , we obtain the following values: $f(1) = 2$ since the point $(1, 2)$ is on the graph of f ; $g(1) = 1$ since the point $(1, 1)$ is on the graph of g ; $f'(1) = 2$ since the slope of the line segment between $(0, 0)$ and $(2, 4)$ is $\frac{4-0}{2-0} = 2$; $g'(1) = -1$ since the slope of the line segment between $(-2, 4)$ and $(2, 0)$ is $\frac{0-4}{2-(-2)} = -1$. Now $u(x) = f(x)g(x)$, so $u'(1) = f(1)g'(1) + g(1)f'(1) = 2 \cdot (-1) + 1 \cdot 2 = 0$.

(b) $v(x) = f(x)/g(x)$, so $v'(5) = \frac{g(5)f'(5) - f(5)g'(5)}{[g(5)]^2} = \frac{2(-\frac{1}{3}) - 3 \cdot \frac{2}{3}}{2^2} = \frac{-\frac{8}{3}}{4} = -\frac{2}{3}$

62. (a) $P(x) = F(x)G(x)$, so $P'(2) = F(2)G'(2) + G(2)F'(2) = 3 \cdot \frac{2}{4} + 2 \cdot 0 = \frac{3}{2}$.

(b) $Q(x) = F(x)/G(x)$, so $Q'(7) = \frac{G(7)F'(7) - F(7)G'(7)}{[G(7)]^2} = \frac{1 \cdot \frac{1}{4} - 5 \cdot (-\frac{2}{3})}{1^2} = \frac{1}{4} + \frac{10}{3} = \frac{43}{12}$

63. (a) $y = xg(x) \Rightarrow y' = xg'(x) + g(x) \cdot 1 = xg'(x) + g(x)$

(b) $y = \frac{x}{g(x)} \Rightarrow y' = \frac{g(x) \cdot 1 - xg'(x)}{[g(x)]^2} = \frac{g(x) - xg'(x)}{[g(x)]^2}$

(c) $y = \frac{g(x)}{x} \Rightarrow y' = \frac{xg'(x) - g(x) \cdot 1}{(x)^2} = \frac{xg'(x) - g(x)}{x^2}$

64. (a) $y = x^2 f(x) \Rightarrow y' = x^2 f'(x) + f(x)(2x)$

(b) $y = \frac{f(x)}{x^2} \Rightarrow y' = \frac{x^2 f'(x) - f(x)(2x)}{(x^2)^2} = \frac{xf'(x) - 2f(x)}{x^3}$

(c) $y = \frac{x^2}{f(x)} \Rightarrow y' = \frac{f(x)(2x) - x^2 f'(x)}{[f(x)]^2}$

(d) $y = \frac{1 + xf(x)}{\sqrt{x}} \Rightarrow$

$$y' = \frac{\sqrt{x}[xf'(x) + f(x)] - [1 + xf(x)] \frac{1}{2\sqrt{x}}}{(\sqrt{x})^2}$$

$$= \frac{x^{3/2}f'(x) + x^{1/2}f(x) - \frac{1}{2}x^{-1/2} - \frac{1}{2}x^{1/2}f(x)}{x} \cdot \frac{2x^{1/2}}{2x^{1/2}} = \frac{xf(x) + 2x^2 f'(x) - 1}{2x^{3/2}}$$

65. $y = f(x) = 1 - x^2 \Rightarrow f'(x) = -2x$, so the tangent line at $(2, -3)$ has slope $f'(2) = -4$. The normal line has slope $-\frac{1}{-4} = \frac{1}{4}$ and equation $y + 3 = \frac{1}{4}(x - 2)$ or $y = \frac{1}{4}x - \frac{7}{2}$.

66. $y = f(x) = x - x^2 \Rightarrow f'(x) = 1 - 2x$. So $f'(1) = -1$, and the slope of the normal line is the negative reciprocal of that of the tangent line, that is, $-1/(-1) = 1$. So the equation of the normal line at $(1, 0)$ is $y - 0 = 1(x - 1)$
 $\Leftrightarrow y = x - 1$. Substituting this into the equation of the parabola, we obtain $x - 1 = x - x^2 \Leftrightarrow x = \pm 1$. The solution $x = -1$ is the one we require. Substituting $x = -1$ into the equation of the parabola to find the y -coordinate, we have $y = -2$. So the point of intersection is $(-1, -2)$, as shown in the sketch.

67. $y = x^3 - x^2 - x + 1$ has a horizontal tangent when $y' = 3x^2 - 2x - 1 = 0$. $(3x + 1)(x - 1) = 0 \Leftrightarrow x = 1$ or $-\frac{1}{3}$. Therefore, the points are $(1, 0)$ and $(-\frac{1}{3}, \frac{32}{27})$.

68. $y = \frac{x-1}{x+1} \Rightarrow y' = \frac{(x+1)(1) - (x-1)(1)}{(x+1)^2} = \frac{2}{(x+1)^2}$. If the tangent intersects the curve when $x = a$, then its slope is $2/(a+1)^2$. But if the tangent is parallel to $x - 2y = 2$,

that is, $y = \frac{1}{2}x - 1$, then its slope is $\frac{1}{2}$. Thus, $\frac{2}{(a+1)^2} = \frac{1}{2} \Rightarrow$

$(a+1)^2 = 4 \Rightarrow a+1 = \pm 2 \Rightarrow a = 1$ or -3 . When $a = 1$, $y = 0$

and the equation of the tangent is $y - 0 = \frac{1}{2}(x - 1)$ or $y = \frac{1}{2}x - \frac{1}{2}$.

When $a = -3$, $y = 2$ and the equation of the tangent is $y - 2 = \frac{1}{2}(x + 3)$

or $y = \frac{1}{2}x + \frac{7}{2}$.

69. If $y = f(x) = \frac{x}{x+1}$, then $f'(x) = \frac{(x+1)(1) - x(1)}{(x+1)^2} = \frac{1}{(x+1)^2}$. When $x = a$, the equation of the tangent

line is $y - \frac{a}{a+1} = \frac{1}{(a+1)^2}(x - a)$. This line passes through $(1, 2)$ when $2 - \frac{a}{a+1} = \frac{1}{(a+1)^2}(1 - a) \Leftrightarrow$

$2(a+1)^2 - a(a+1) = 1 - a \Leftrightarrow 2a^2 + 4a + 2 - a^2 - a - 1 + a = 0 \Leftrightarrow a^2 + 4a + 1 = 0$.

The quadratic formula gives the roots of this equation as $a = \frac{-4 \pm \sqrt{4^2 - 4(1)(1)}}{2(1)} = \frac{-4 \pm \sqrt{12}}{2} = -2 \pm \sqrt{3}$,

so there are two such tangent lines. Since

$$\begin{aligned} f(-2 \pm \sqrt{3}) &= \frac{-2 \pm \sqrt{3}}{-2 \pm \sqrt{3} + 1} = \frac{-2 \pm \sqrt{3}}{-1 \pm \sqrt{3}} \cdot \frac{-1 \mp \sqrt{3}}{-1 \mp \sqrt{3}} \\ &= \frac{2 \pm 2\sqrt{3} \mp \sqrt{3} - 3}{1 - 3} = \frac{-1 \pm \sqrt{3}}{-2} = \frac{1 \mp \sqrt{3}}{2}, \end{aligned}$$

the lines touch the curve at $A(-2 + \sqrt{3}, \frac{1 - \sqrt{3}}{2}) \approx (-0.27, -0.37)$ and

$B(-2 - \sqrt{3}, \frac{1 + \sqrt{3}}{2}) \approx (-3.73, 1.37)$.

70.

Let (a, a^2) be a point on the parabola at which the tangent line passes through the point $(0, -4)$. The tangent line has slope $2a$ and equation

$y - (-4) = 2a(x - 0) \Leftrightarrow y = 2ax - 4$. Since (a, a^2) also lies on

the line, $a^2 = 2a(a) - 4$, or $a^2 = 4$. So $a = \pm 2$ and the points are $(2, 4)$ and $(-2, 4)$.

71. $y = 6x^3 + 5x - 3 \Rightarrow m = y' = 18x^2 + 5$, but $x^2 \geq 0$ for all x , so $m \geq 5$ for all x .

72. If $y = x^2 + x$, then $y' = 2x + 1$. If the point at which a tangent meets the parabola is $(a, a^2 + a)$, then the slope of the tangent is $2a + 1$. But since it passes through $(2, -3)$, the slope must also be $\frac{\Delta y}{\Delta x} = \frac{a^2 + a + 3}{a - 2}$.

Therefore, $2a + 1 = \frac{a^2 + a + 3}{a - 2}$. Solving this equation for a we get $a^2 + a + 3 = 2a^2 - 3a - 2 \Leftrightarrow$

$a^2 - 4a - 5 = (a - 5)(a + 1) = 0 \Leftrightarrow a = 5$ or -1 . If $a = -1$, the point is $(-1, 0)$ and the slope is -1 , so the equation is $y - 0 = (-1)(x + 1)$ or $y = -x - 1$. If $a = 5$, the point is $(5, 30)$ and the slope is 11 , so the equation is $y - 30 = 11(x - 5)$ or $y = 11x - 25$.

73. (a) $(fgh)' = [(fg)h]' = (fg)'h + (fg)h' = (f'g + fg')h + (fg)h' = f'gh + fg'h + fgh'$

(b) $y = \sqrt{x}(x^4 + x + 1)(2x - 3)$. Using part (a), we have

$$\begin{aligned} y' &= \frac{1}{2\sqrt{x}}(x^4 + x + 1)(2x - 3) + \sqrt{x}(4x^3 + 1)(2x - 3) + \sqrt{x}(x^4 + x + 1)(2) \\ &= (x^4 + x + 1)\frac{2x - 3}{2\sqrt{x}} + \sqrt{x}[(4x^3 + 1)(2x - 3) + 2(x^4 + x + 1)] \end{aligned}$$

74. (a) Putting $f = g = h$ in part (a), we have

$$\frac{d}{dx}[f(x)]^3 = (fff)' = f'ff + ff'f + fff' = 3fff' = 3[f(x)]^2 f'(x).$$

(b) $y = (x^4 + 3x^3 + 17x + 82)^3 \Rightarrow y' = 3(x^4 + 3x^3 + 17x + 82)^2(4x^3 + 9x^2 + 17)$

75. $y = f(x) = ax^3 + bx^2 + cx + d \Rightarrow f'(x) = 3ax^2 + 2bx + c$. The point $(-2, 6)$ is on f , so $f(-2) = 6 \Rightarrow -8a + 4b - 2c + d = 6$ (1). The point $(2, 0)$ is on f , so $f(2) = 0 \Rightarrow 8a + 4b + 2c + d = 0$ (2). Since there are horizontal tangents at $(-2, 6)$ and $(2, 0)$, $f'(\pm 2) = 0$. $f'(-2) = 0 \Rightarrow 12a - 4b + c = 0$ (3) and $f'(2) = 0 \Rightarrow 12a + 4b + c = 0$ (4). Subtracting equation (3) from (4) gives $8b = 0 \Rightarrow b = 0$. Adding (1) and (2) gives $8b + 2d = 6$, so $d = 3$ since $b = 0$. From (3) we have $c = -12a$, so (2) becomes $8a + 4(0) + 2(-12a) + 3 = 0 \Rightarrow 3 = 16a \Rightarrow a = \frac{3}{16}$. Now $c = -12a = -12(\frac{3}{16}) = -\frac{9}{4}$ and the desired cubic function is $y = \frac{3}{16}x^3 - \frac{9}{4}x + 3$.

76. (a) $s(0) = 100,000$ subscribers and $n(0) = 1.2$ phone lines per subscriber. $s'(0) = 1000$ subscribers/month and $n'(0) = 0.01$ phone line per subscriber/month.

(b) The total number of lines is given by $L(t) = s(t)n(t)$. To find $L'(0)$, we first find $L'(t)$ using the Product Rule. $L'(t) = s(t)n'(t) + n(t)s'(t) \Rightarrow L'(0) = s(0)n'(0) + n(0)s'(0) = 100,000(0.01) + 1.2(1000) = 2200$ phone lines/month.

77. If $P(t)$ denotes the population at time t and $A(t)$ the average annual income, then $T(t) = P(t)A(t)$ is the total personal income. The rate at which $T(t)$ is rising is given by $T'(t) = P(t)A'(t) + A(t)P'(t) \Rightarrow T'(1999) = P(1999)A'(1999) + A(1999)P'(1999) = (961,400)(\$1400/\text{yr}) + (\$30,593)(9200/\text{yr}) = \$1,345,960,000/\text{yr} + \$281,455,600/\text{yr} = \$1,627,415,600/\text{yr}$

So the total personal income was rising by about \$1.627 billion per year in 1999.

The term $P(t)A'(t) \approx \$1.346$ billion represents the portion of the rate of change of total income due to the existing population's increasing income. The term $A(t)P'(t) \approx \$281$ million represents the portion of the rate of change of total income due to increasing population.

78. (a) $f(20) = 10,000$ means that when the price of the fabric is \$20/yard, 10,000 yards will be sold. $f'(20) = -350$ means that as the price of the fabric increases past \$20/yard, the amount of fabric which will be sold is decreasing at a rate of 350 yards per (dollar per yard).

(b) $R(p) = pf(p) \Rightarrow R'(p) = pf'(p) + f(p) \cdot 1 \Rightarrow R'(20) = 20f'(20) + f(20) \cdot 1 = 20(-350) + 10,000 = 3000$. This means that as the price of the fabric increases past \$20/yard, the total revenue is increasing at \$3000/(\$/yard). Note that the Product Rule indicates that we will lose \$7000/(\$/yard) due to selling less fabric, but that that loss is more than made up for by the additional revenue due to the increase in price.

79. $f(x) = 2 - x$ if $x \leq 1$ and $f(x) = x^2 - 2x + 2$ if $x > 1$. Now we compute the right- and left-hand derivatives defined in Exercise 3.2.44:

$$f'_-(1) = \lim_{h \rightarrow 0^-} \frac{f(1+h) - f(1)}{h} = \lim_{h \rightarrow 0^-} \frac{2 - (1+h) - 1}{h} = \lim_{h \rightarrow 0^-} \frac{-h}{h} = \lim_{h \rightarrow 0^-} -1 = -1 \text{ and}$$

$$f'_+(1) = \lim_{h \rightarrow 0^+} \frac{f(1+h) - f(1)}{h} = \lim_{h \rightarrow 0^+} \frac{(1+h)^2 - 2(1+h) + 2 - 1}{h} = \lim_{h \rightarrow 0^+} \frac{h^2}{h} = \lim_{h \rightarrow 0^+} h = 0.$$

Thus, $f'(1)$ does not exist since $f'_-(1) \neq f'_+(1)$,

so f is not differentiable at 1. But $f'(x) = -1$

for $x < 1$ and $f'(x) = 2x - 2$ if $x > 1$.

$$80. g(x) = \begin{cases} -1 - 2x & \text{if } x < -1 \\ x^2 & \text{if } -1 \leq x \leq 1 \\ x & \text{if } x > 1 \end{cases}$$

$$\lim_{h \rightarrow 0^-} \frac{g(-1+h) - g(-1)}{h} = \lim_{h \rightarrow 0^-} \frac{[-1 - 2(-1+h)] - 1}{h} = \lim_{h \rightarrow 0^-} \frac{-2h}{h} = \lim_{h \rightarrow 0^-} (-2) = -2 \text{ and}$$

$$\lim_{h \rightarrow 0^+} \frac{g(-1+h) - g(-1)}{h} = \lim_{h \rightarrow 0^+} \frac{(-1+h)^2 - 1}{h} = \lim_{h \rightarrow 0^+} \frac{-2h + h^2}{h} = \lim_{h \rightarrow 0^+} (-2 + h) = -2,$$

so g is differentiable at -1 and $g'(-1) = -2$.

$$\lim_{h \rightarrow 0^-} \frac{g(1) - g(1)}{h} = \lim_{h \rightarrow 0^-} \frac{(1)^2 - 1}{h} = \lim_{h \rightarrow 0^-} \frac{2h + h^2}{h} = \lim_{h \rightarrow 0^-} (2 + h) = 2 \text{ and}$$

$$\lim_{h \rightarrow 0^+} \frac{g(1) - g(1)}{h} = \lim_{h \rightarrow 0^+} \frac{(1) - 1}{h} = \lim_{h \rightarrow 0^+} \frac{h}{h} = \lim_{h \rightarrow 0^+} 1 = 1, \text{ so } g'(1) \text{ does not exist.}$$

Thus, g is differentiable except when $x = 1$, and

$$g'(x) = \begin{cases} -2 & \text{if } x < -1 \\ 2x & \text{if } -1 \leq x < 1 \\ 1 & \text{if } x > 1 \end{cases}$$

81. (a) Note that $x^2 - 9 < 0$ for $x^2 < 9 \Leftrightarrow |x| < 3 \Leftrightarrow -3 < x < 3$. So

$$f(x) = \begin{cases} x^2 - 9 & \text{if } x \leq -3 \\ -x^2 + 9 & \text{if } -3 < x < 3 \\ x^2 - 9 & \text{if } x \geq 3 \end{cases} \Rightarrow$$

$$f'(x) = \begin{cases} 2x & \text{if } x < -3 \\ -2x & \text{if } -3 < x < 3 \\ 2x & \text{if } x > 3 \end{cases} = \begin{cases} 2x & \text{if } |x| > 3 \\ -2x & \text{if } |x| < 3 \end{cases}$$

To show that $f'(3)$ does not exist we investigate $\lim_{h \rightarrow 0} \frac{f(3+h) - f(3)}{h}$ by computing the left- and right-hand derivatives defined in Exercise 3.2.44.

$$f'_-(3) = \lim_{h \rightarrow 0^-} \frac{f(3+h) - f(3)}{h} = \lim_{h \rightarrow 0^-} \frac{[-(3+h)^2 + 9] - 0}{h} = \lim_{h \rightarrow 0^-} (-6 - h) = -6 \quad \text{and}$$

$$f'_+(3) = \lim_{h \rightarrow 0^+} \frac{f(3+h) - f(3)}{h} = \lim_{h \rightarrow 0^+} \frac{[(3+h)^2 - 9] - 0}{h} = \lim_{h \rightarrow 0^+} \frac{6h + h^2}{h} = \lim_{h \rightarrow 0^+} (6 + h) = 6.$$

Since the left and right limits are different,

$$\lim_{h \rightarrow 0} \frac{f(3+h) - f(3)}{h} \text{ does not exist, that is,}$$

$f'(3)$ does not exist. Similarly, $f'(-3)$ does not exist. Therefore, f is not differentiable at 3 or at -3 .

- 82.** If $x > 1$, then $h(x) = |x - 1| + |x + 2| = x - 1 + x + 2 = 2x + 1$.

If $-2 < x < 1$, then $h(x) = -(x - 1) + x + 2 = 3$.

If $x < -2$, then $h(x) = -(x - 1) - (x + 2) = -2x - 1$. Therefore,

$$h(x) = \begin{cases} -2x - 1 & \text{if } x \leq -2 \\ 3 & \text{if } -2 < x < 1 \\ 2x + 1 & \text{if } x > 1 \end{cases} \Rightarrow h'(x) = \begin{cases} -2 & \text{if } x < -2 \\ 0 & \text{if } -2 < x < 1 \\ 2 & \text{if } x > 1 \end{cases}$$

To see that $h'(1) = \lim_{x \rightarrow 1} \frac{h(x) - h(1)}{x - 1}$ does not exist,

observe that $\lim_{x \rightarrow 1^-} \frac{h(x) - h(1)}{x - 1} = \lim_{x \rightarrow 1^-} \frac{3 - 3}{3 - 1} = 0$ but

$$\lim_{x \rightarrow 1^+} \frac{h(x) - h(1)}{x - 1} = \lim_{x \rightarrow 1^+} \frac{2x - 2}{x - 1} = 2. \text{ Similarly,}$$

$h'(-2)$ does not exist.

- 83.** $y = f(x) = ax^2 \Rightarrow f'(x) = 2ax$. So the slope of the tangent to the parabola at $x = 2$ is $m = 2a(2) = 4a$. The slope of the given line, $2x + y = b \Leftrightarrow y = -2x + b$, is seen to be -2 , so we must have $4a = -2 \Leftrightarrow a = -\frac{1}{2}$. So when $x = 2$, the point in question has y -coordinate $-\frac{1}{2} \cdot 2^2 = -2$. Now we simply require that the given line, whose equation is $2x + y = b$, pass through the point $(2, -2)$: $2(2) + (-2) = b \Leftrightarrow b = 2$. So we must have $a = -\frac{1}{2}$ and $b = 2$.
- 84.** f is clearly differentiable for $x < 2$ and for $x > 2$. For $x < 2$, $f'(x) = 2x$, so $f'_-(2) = 4$. For $x > 2$, $f'(x) = m$, so $f'_+(2) = m$. For f to be differentiable at $x = 2$, we need $4 = f'_-(2) = f'_+(2) = m$. So $f(x) = 4x + b$. We must also have continuity at $x = 2$, so $4 = f(2) = \lim_{x \rightarrow 2^+} f(x) = \lim_{x \rightarrow 2^+} (4x + b) = 8 + b$. Hence, $b = -4$.
- 85.** $F = f/g \Rightarrow f = Fg \Rightarrow f' = F'g + Fg' \Rightarrow F' = \frac{f' - Fg'}{g} = \frac{f' - (f/g)g'}{g} = \frac{f'g - fg'}{g^2}$
- 86.** (a) $xy = c \Rightarrow y = \frac{c}{x}$. Let $P = \left(a, \frac{c}{a}\right)$. The slope of the tangent line at $x = a$ is $y'(a) = -\frac{c}{a^2}$. Its equation is $y - \frac{c}{a} = -\frac{c}{a^2}(x - a)$ or $y = -\frac{c}{a^2}x + \frac{2c}{a}$, so its y -intercept is $\frac{2c}{a}$. Setting $y = 0$ gives $x = 2a$, so the x -intercept is $2a$. The midpoint of the line segment joining $\left(0, \frac{2c}{a}\right)$ and $(2a, 0)$ is $\left(a, \frac{c}{a}\right) = P$.

(b) We know the x - and y -intercepts of the tangent line from part (a), so the area of the triangle bounded by the axes and the tangent is $\frac{1}{2}(\text{base})(\text{height}) = \frac{1}{2}xy = \frac{1}{2}(2a)(2c/a) = 2c$, a constant.

87. Solution 1: Let $f(x) = x^{1000}$. Then, by the definition of a derivative,

$$f'(1) = \lim_{x \rightarrow 1} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1} \frac{x^{1000} - 1}{x - 1}. \text{ But this is just the limit we want to find, and we know (from the}$$

Power Rule) that $f'(x) = 1000x^{999}$, so $f'(1) = 1000(1)^{999} = 1000$. So $\lim_{x \rightarrow 1} \frac{x^{1000} - 1}{x - 1} = 1000$.

Solution 2: Note that $(x^{1000} - 1) = (x - 1)(x^{999} + x^{998} + x^{997} + \cdots + x^2 + x + 1)$. So

$$\begin{aligned} \lim_{x \rightarrow 1} \frac{x^{1000} - 1}{x - 1} &= \lim_{x \rightarrow 1} \frac{(x - 1)(x^{999} + x^{998} + x^{997} + \cdots + x^2 + x + 1)}{x - 1} \\ &= \lim_{x \rightarrow 1} (x^{999} + x^{998} + x^{997} + \cdots + x^2 + x + 1) = \underbrace{1 + 1 + 1 + \cdots + 1 + 1 + 1}_{1000 \text{ ones}} \\ &= 1000, \text{ as above.} \end{aligned}$$

88.

In order for the two tangents to intersect on the y -axis, the points of tangency must be at equal distances from the y -axis, since the parabola $y = x^2$ is symmetric about the y -axis. Say the points of tangency are (a, a^2) and $(-a, a^2)$, for some $a > 0$. Then since the derivative of $y = x^2$ is $dy/dx = 2x$, the left-hand tangent has slope $-2a$ and equation $y - a^2 = -2a(x + a)$, or $y = -2ax - a^2$, and similarly the right-hand tangent line has equation

$y - a^2 = 2a(x - a)$, or $y = 2ax - a^2$. So the two lines intersect at $(0, -a^2)$. Now if the lines are perpendicular, then the product of their slopes is -1 , so $(-2a)(2a) = -1 \Leftrightarrow a^2 = \frac{1}{4} \Leftrightarrow a = \frac{1}{2}$. So the lines intersect at $(0, -\frac{1}{4})$.

3.4 Rates of Change in the Natural and Social Sciences

1. (a) $s = f(t) = t^2 - 10t + 12 \Rightarrow v(t) = f'(t) = 2t - 10$

(b) $v(3) = 2(3) - 10 = -4$ ft/s

(c) The particle is at rest when $v(t) = 0 \Leftrightarrow 2t - 10 = 0 \Leftrightarrow t = 5$ s.

(d) The particle is moving in the positive direction when $v(t) > 0 \Leftrightarrow 2t - 10 > 0 \Leftrightarrow 2t > 10 \Leftrightarrow t > 5$.

(e) Since the particle is moving in the positive direction (f)

and in the negative direction, we need to calculate the

distance traveled in the intervals $[0, 5]$ and $[5, 8]$

separately. $|f(5) - f(0)| = |-13 - 12| = 25$ ft and

$|f(8) - f(5)| = |-4 - (-13)| = 9$ ft. The total

distance traveled during the first 8 s is $25 + 9 = 34$ ft.

$$2. (a) s = f(t) = t^3 - 9t^2 + 15t + 10 \Rightarrow v(t) = f'(t) = 3t^2 - 18t + 15 = 3(t-1)(t-5)$$

$$(b) v(3) = 3(2)(-2) = -12 \text{ ft/s}$$

$$(c) v(t) = 0 \Leftrightarrow t = 1 \text{ s or } 5 \text{ s}$$

$$(d) v(t) > 0 \Leftrightarrow 0 \leq t < 1 \text{ or } t > 5$$

$$(e) |f(1) - f(0)| = |17 - 10| = 7,$$

$$|f(5) - f(1)| = |-15 - 17| = 32, \text{ and}$$

$$|f(8) - f(5)| = |66 - (-15)| = 81.$$

$$\text{Total distance} = 7 + 32 + 81 = 120 \text{ ft.}$$

$$3. (a) s = f(t) = t^3 - 12t^2 + 36t \Rightarrow v(t) = f'(t) = 3t^2 - 24t + 36$$

$$(b) v(3) = 27 - 72 + 36 = -9 \text{ ft/s}$$

$$(c) \text{The particle is at rest when } v(t) = 0. 3t^2 - 24t + 36 = 0 \Rightarrow 3(t-2)(t-6) = 0 \Rightarrow t = 2 \text{ s or } 6 \text{ s.}$$

$$(d) \text{The particle is moving in the positive direction when } v(t) > 0. 3(t-2)(t-6) > 0 \Leftrightarrow 0 \leq t < 2 \text{ or } t > 6.$$

(e) Since the particle is moving in the positive direction and in the negative direction, we need to calculate the distance traveled in the intervals $[0, 2]$, $[2, 6]$, and $[6, 8]$ separately.

$$|f(2) - f(0)| = |32 - 0| = 32.$$

$$|f(6) - f(2)| = |0 - 32| = 32.$$

$$|f(8) - f(6)| = |32 - 0| = 32.$$

$$\text{The total distance is } 32 + 32 + 32 = 96 \text{ ft.}$$

$$4. (a) s = f(t) = t^4 - 4t + 1 \Rightarrow v(t) = f'(t) = 4t^3 - 4$$

$$(b) v(3) = 4(3)^3 - 4 = 104 \text{ ft/s}$$

$$(c) \text{It is at rest when } v(t) = 4(t^3 - 1) = 4(t-1)(t^2 + t + 1) = 0 \Leftrightarrow t = 1 \text{ s.}$$

$$(d) \text{It moves in the positive direction when } 4(t^3 - 1) > 0 \Leftrightarrow t > 1.$$

$$(e) \text{Distance in positive direction} = |f(8) - f(1)| = |4065 - (-2)| = 4067 \text{ ft}$$

$$\text{Distance in negative direction} = |f(1) - f(0)| = |-2 - 1| = 3 \text{ ft}$$

$$\text{Total distance traveled} = 4067 + 3 = 4070 \text{ ft}$$

$$5. (a) s = \frac{t}{t^2 + 1} \Rightarrow v(t) = s'(t) = \frac{(t^2 + 1)(1) - t(2t)}{(t^2 + 1)^2} = \frac{1 - t^2}{(t^2 + 1)^2}$$

$$(b) v(3) = \frac{1 - (3)^2}{(3^2 + 1)^2} = \frac{1 - 9}{10^2} = \frac{-8}{100} = -\frac{2}{25} \text{ ft/s}$$

$$(c) \text{It is at rest when } v = 0 \Leftrightarrow 1 - t^2 = 0 \Leftrightarrow t = 1 \text{ s } [t \neq -1 \text{ since } t \geq 0].$$

$$(d) \text{It moves in the positive direction when } v > 0 \Leftrightarrow 1 - t^2 > 0 \Leftrightarrow t^2 < 1 \Leftrightarrow 0 \leq t < 1.$$

- (e) Distance in positive direction $= |s(1) - s(0)| = \left| \frac{1}{2} - 0 \right| = \frac{1}{2}$ ft
 Distance in negative direction $= |s(8) - s(1)| = \left| \frac{8}{65} - \frac{1}{2} \right| = \frac{49}{130}$ ft
 Total distance traveled $= \frac{1}{2} + \frac{49}{130} = \frac{57}{65}$ ft

6. (a) $s = \sqrt{t}(3t^2 - 35t + 90) = 3t^{5/2} - 35t^{3/2} + 90t^{1/2} \Rightarrow$
 $v(t) = s'(t) = \frac{15}{2}t^{3/2} - \frac{105}{2}t^{1/2} + 45t^{-1/2} = \frac{15}{2}t^{-1/2}(t^2 - 7t + 6) = \frac{15}{2\sqrt{t}}(t-1)(t-6)$
 (b) $v(3) = \frac{15}{2\sqrt{3}}(2)(-3) = -15\sqrt{3}$ ft/s
 (c) It is at rest when $v = 0 \Leftrightarrow t = 1$ s or 6 s.
 (d) It moves in the positive direction when $v > 0 \Leftrightarrow (t-1)(t-6) > 0 \Leftrightarrow 0 \leq t < 1$ or $t > 6$.
 (e) Distance in positive direction $= |s(1) - s(0)| + |s(8) - s(6)| = |58 - 0| + |4\sqrt{2} - (-12\sqrt{6})|$
 $= 58 + 4\sqrt{2} + 12\sqrt{6} \approx 93.05$ ft
 Distance in negative direction $= |s(6) - s(1)| = |-12\sqrt{6} - 58| = 58 + 12\sqrt{6} \approx 87.39$ ft
 Total distance traveled $= 58 + 4\sqrt{2} + 12\sqrt{6} + 58 + 12\sqrt{6} = 116 + 4\sqrt{2} + 24\sqrt{6} \approx 180.44$ ft

7. $s(t) = t^3 - 4.5t^2 - 7t \Rightarrow v(t) = s'(t) = 3t^2 - 9t - 7 = 5 \Leftrightarrow 3t^2 - 9t - 12 = 0 \Leftrightarrow$
 $3(t-4)(t+1) = 0 \Leftrightarrow t = 4$ or -1 . Since $t \geq 0$, the particle reaches a velocity of 5 m/s at $t = 4$ s.
8. (a) $s = 5t + 3t^2 \Rightarrow v(t) = \frac{ds}{dt} = 5 + 6t$, so $v(2) = 5 + 6(2) = 17$ m/s.
 (b) $v(t) = 35 \Rightarrow 5 + 6t = 35 \Rightarrow 6t = 30 \Rightarrow t = 5$ s.
9. (a) $h = 10t - 0.83t^2 \Rightarrow v(t) = \frac{dh}{dt} = 10 - 1.66t$, so $v(3) = 10 - 1.66(3) = 5.02$ m/s.
 (b) $h = 25 \Rightarrow 10t - 0.83t^2 = 25 \Rightarrow 0.83t^2 - 10t + 25 = 0 \Rightarrow t = \frac{10 \pm \sqrt{17}}{1.66} \approx 3.54$ or 8.51 .
 The value $t_1 = (10 - \sqrt{17})/1.66$ corresponds to the time it takes for the stone to rise 25 m and
 $t_2 = (10 + \sqrt{17})/1.66$ corresponds to the time when the stone is 25 m high on the way down. Thus,
 $v(t_1) = 10 - 1.66[(10 - \sqrt{17})/1.66] = \sqrt{17} \approx 4.12$ m/s.

10. (a) At maximum height the velocity of the ball is 0 ft/s. $v(t) = s'(t) = 80 - 32t = 0 \Leftrightarrow 32t = 80 \Leftrightarrow t = \frac{5}{2}$. So the maximum height is $s(\frac{5}{2}) = 80(\frac{5}{2}) - 16(\frac{5}{2})^2 = 200 - 100 = 100$ ft.
- (b) $s(t) = 80t - 16t^2 = 96 \Leftrightarrow 16t^2 - 80t + 96 = 0 \Leftrightarrow 16(t^2 - 5t + 6) = 0 \Leftrightarrow 16(t-3)(t-2) = 0$. So the ball has a height of 96 ft on the way up at $t = 2$ and on the way down at $t = 3$. At these times the velocities are $v(2) = 80 - 32(2) = 16$ ft/s and $v(3) = 80 - 32(3) = -16$ ft/s, respectively.

11. (a) $A(x) = x^2 \Rightarrow A'(x) = 2x$. $A'(15) = 30$ mm²/mm is the rate at which the area is increasing with respect to the side length as x reaches 15 mm.

- (b) The perimeter is $P(x) = 4x$, so $A'(x) = 2x = \frac{1}{2}(4x) = \frac{1}{2}P(x)$.

The figure suggests that if Δx is small, then the change in the area of the square is approximately half of its perimeter (2 of the 4 sides) times Δx . From the figure, $\Delta A = 2x(\Delta x) + (\Delta x)^2$. If Δx is small, then $\Delta A \approx 2x(\Delta x)$ and so $\Delta A/\Delta x \approx 2x$.

12. (a) $V(x) = x^3 \Rightarrow \frac{dV}{dx} = 3x^2$. $\frac{dV}{dx} \Big|_{x=3} = 3(3)^2 = 27$ mm³/mm is the rate at which the volume is increasing as x increases past 3 mm.

- (b) The surface area is $S(x) = 6x^2$, so

$V'(x) = 3x^2 = \frac{1}{2}(6x^2) = \frac{1}{2}S(x)$. The figure suggests that if Δx is small, then the change in the volume of the cube is approximately half of its surface area (the area of 3 of the 6 faces) times Δx . From the figure, $\Delta V = 3x^2(\Delta x) + 3x(\Delta x)^2 + (\Delta x)^3$. If Δx is small, then $\Delta V \approx 3x^2(\Delta x)$ and so $\Delta V/\Delta x \approx 3x^2$.

13. (a) Using $A(r) = \pi r^2$, we find that the average rate of change is:

$$(i) \frac{A(3) - A(2)}{3 - 2} = \frac{9\pi - 4\pi}{1} = 5\pi$$

$$(ii) \frac{A(2.5) - A(2)}{2.5 - 2} = \frac{6.25\pi - 4\pi}{0.5} = 4.5\pi$$

$$(iii) \frac{A(2.1) - A(2)}{2.1 - 2} = \frac{4.41\pi - 4\pi}{0.1} = 4.1\pi$$

- (b) $A(r) = \pi r^2 \Rightarrow A'(r) = 2\pi r$, so $A'(2) = 4\pi$.

- (c) The circumference is $C(r) = 2\pi r = A'(r)$. The figure suggests that if Δr is small, then the change in the area of the circle (a ring around the outside) is approximately equal to its circumference times Δr . Straightening out this ring gives us a shape that is approximately rectangular with length $2\pi r$ and width Δr , so $\Delta A \approx 2\pi r(\Delta r)$. Algebraically,

$$\Delta A = A(r + \Delta r) - A(r) = \pi(r + \Delta r)^2 - \pi r^2 = 2\pi r(\Delta r) + \pi(\Delta r)^2.$$

So we see that if Δr is small, then $\Delta A \approx 2\pi r(\Delta r)$ and therefore,

$$\Delta A/\Delta r \approx 2\pi r.$$

14. After t seconds the radius is $r = 60t$, so the area is $A(t) = \pi(60t)^2 = 3600\pi t^2 \Rightarrow A'(t) = 7200\pi t \Rightarrow$

(a) $A'(1) = 7200\pi \text{ cm}^2/\text{s}$ (b) $A'(3) = 21,600\pi \text{ cm}^2/\text{s}$ (c) $A'(5) = 36,000\pi \text{ cm}^2/\text{s}$

As time goes by, the area grows at an increasing rate. In fact, the rate of change is linear with respect to time.

15. $S(r) = 4\pi r^2 \Rightarrow S'(r) = 8\pi r \Rightarrow$

(a) $S'(1) = 8\pi \text{ ft}^2/\text{ft}$ (b) $S'(2) = 16\pi \text{ ft}^2/\text{ft}$ (c) $S'(3) = 24\pi \text{ ft}^2/\text{ft}$

As the radius increases, the surface area grows at an increasing rate. In fact, the rate of change is linear with respect to the radius.

16. (a) Using $V(r) = \frac{4}{3}\pi r^3$, we find that the average rate of change is:

(i) $\frac{V(8) - V(5)}{8 - 5} = \frac{\frac{4}{3}\pi(512) - \frac{4}{3}\pi(125)}{3} = 172\pi \mu\text{m}^3/\mu\text{m}$

(ii) $\frac{V(6) - V(5)}{6 - 5} = \frac{\frac{4}{3}\pi(216) - \frac{4}{3}\pi(125)}{1} = 121.\bar{3}\pi \mu\text{m}^3/\mu\text{m}$

(iii) $\frac{V(5.1) - V(5)}{5.1 - 5} = \frac{\frac{4}{3}\pi(5.1)^3 - \frac{4}{3}\pi(5)^3}{0.1} = 102.01\bar{3}\pi \mu\text{m}^3/\mu\text{m}$

(b) $V'(r) = 4\pi r^2$, so $V'(5) = 100\pi \mu\text{m}^3/\mu\text{m}$.

- (c) $V(r) = \frac{4}{3}\pi r^3 \Rightarrow V'(r) = 4\pi r^2 = S(r)$. By analogy with Exercise 13(c), we can say that the change in the volume of the spherical shell, ΔV , is approximately equal to its thickness, Δr , times the surface area of the inner sphere. Thus, $\Delta V \approx 4\pi r^2(\Delta r)$ and so $\Delta V/\Delta r \approx 4\pi r^2$.

17. The mass is $f(x) = 3x^2$, so the linear density at x is $\rho(x) = f'(x) = 6x$.

(a) $\rho(1) = 6 \text{ kg/m}$ (b) $\rho(2) = 12 \text{ kg/m}$ (c) $\rho(3) = 18 \text{ kg/m}$

Since ρ is an increasing function, the density will be the highest at the right end of the rod and lowest at the left end.

18. $V(t) = 5000(1 - \frac{1}{40}t)^2 = 5000(1 - \frac{1}{20}t + \frac{1}{1600}t^2) \Rightarrow V'(t) = 5000(-\frac{1}{20} + \frac{1}{800}t) = -250(1 - \frac{1}{40}t)$

(a) $V'(5) = -250(1 - \frac{5}{40}) = -218.75 \text{ gal/min}$ (b) $V'(10) = -250(1 - \frac{10}{40}) = -187.5 \text{ gal/min}$

(c) $V'(20) = -250(1 - \frac{20}{40}) = -125 \text{ gal/min}$ (d) $V'(40) = -250(1 - \frac{40}{40}) = 0 \text{ gal/min}$

The water is flowing out the fastest at the beginning—when $t = 0$, $V'(t) = -250 \text{ gal/min}$. The water is flowing out the slowest at the end—when $t = 40$, $V'(t) = 0$. As the tank empties, the water flows out more slowly.

19. The quantity of charge is $Q(t) = t^3 - 2t^2 + 6t + 2$, so the current is $Q'(t) = 3t^2 - 4t + 6$.

(a) $Q'(0.5) = 3(0.5)^2 - 4(0.5) + 6 = 4.75 \text{ A}$ (b) $Q'(1) = 3(1)^2 - 4(1) + 6 = 5 \text{ A}$

The current is lowest when Q' has a minimum. $Q''(t) = 6t - 4 < 0$ when $t < \frac{2}{3}$. So the current decreases when $t < \frac{2}{3}$ and increases when $t > \frac{2}{3}$. Thus, the current is lowest at $t = \frac{2}{3} \text{ s}$.

20. (a) $F = \frac{GmM}{r^2} = (GmM)r^{-2} \Rightarrow \frac{dF}{dr} = -2(GmM)r^{-3} = -\frac{2GmM}{r^3}$, which is the rate of change of the force with respect to the distance between the bodies. The minus sign indicates that as the distance r between the bodies increases, the magnitude of the force F exerted by the body of mass m on the body of mass M is decreasing.

(b) Given $F'(20,000) = -2$, find $F'(10,000)$. $-2 = -\frac{2GmM}{20,000^3} \Rightarrow GmM = 20,000^3$.

$F'(10,000) = -\frac{2(20,000^3)}{10,000^3} = -2 \cdot 2^3 = -16 \text{ N/km}$

21. (a) To find the rate of change of volume with respect to pressure, we first solve for V in terms of P .

$$PV = C \Rightarrow V = \frac{C}{P} \Rightarrow \frac{dV}{dP} = -\frac{C}{P^2}.$$

- (b) From the formula for dV/dP in part (a), we see that as P increases, the absolute value of dV/dP decreases. Thus, the volume is decreasing more rapidly at the beginning.

$$(c) \beta = -\frac{1}{V} \frac{dV}{dP} = -\frac{1}{V} \left(-\frac{C}{P^2} \right) = \frac{C}{(PV)P} = \frac{C}{CP} = \frac{1}{P}$$

$$\begin{aligned} 22. (a) \quad (i) \quad \frac{C(6) - C(2)}{6 - 2} &= \frac{0.0295 - 0.0570}{4} \\ &= -0.006875 \text{ (moles/L)/min} \\ (ii) \quad \frac{C(4) - C(2)}{4 - 2} &= \frac{0.0408 - 0.0570}{2} \\ &= -0.008 \text{ (moles/L)/min} \\ (iii) \quad \frac{C(2) - C(0)}{2 - 0} &= \frac{0.0570 - 0.0800}{2} \\ &= -0.0115 \text{ (moles/L)/min} \end{aligned}$$

$$(b) \text{ Slope} = \frac{\Delta C}{\Delta t} \approx -\frac{0.077}{7.8} \approx -0.01 \text{ (moles/L)/min}$$

$$\begin{aligned} 23. (a) \quad 1920: m_1 &= \frac{1860 - 1750}{1920 - 1910} = \frac{110}{10} = 11, m_2 = \frac{2070 - 1860}{1930 - 1920} = \frac{210}{10} = 21, \\ (m_1 + m_2)/2 &= (11 + 21)/2 = 16 \text{ million/year} \\ 1980: m_1 &= \frac{4450 - 3710}{1980 - 1970} = \frac{740}{10} = 74, m_2 = \frac{5280 - 4450}{1990 - 1980} = \frac{830}{10} = 83, \\ (m_1 + m_2)/2 &= (74 + 83)/2 = 78.5 \text{ million/year} \end{aligned}$$

- (b) $P(t) = at^3 + bt^2 + ct + d$ (in millions of people), where $a \approx 0.0012937063$, $b \approx -7.061421911$, $c \approx 12,822.97902$, and $d \approx -7,743,770.396$.

$$(c) P(t) = at^3 + bt^2 + ct + d \Rightarrow P'(t) = 3at^2 + 2bt + c \text{ (in millions of people per year)}$$

$$\begin{aligned} (d) P'(1920) &= 3(0.0012937063)(1920)^2 + 2(-7.061421911)(1920) + 12,822.97902 \\ &\approx 14.48 \text{ million/year [smaller than the answer in part (a), but close to it]} \\ P'(1980) &\approx 75.29 \text{ million/year (smaller, but close)} \end{aligned}$$

- (e) $P'(1985) \approx 81.62$ million/year, so the rate of growth in 1985 was about 81.62 million/year.

$$24. (a) A(t) = at^4 + bt^3 + ct^2 + dt + e, \text{ where } a = -5.8275058275396 \times 10^{-6}, b = 0.0460458430461, \\ c = -136.43277039706, d = 179,661.02676871, \text{ and } e = -88,717,597.060767.$$

$$(b) A(t) = at^4 + bt^3 + ct^2 + dt + e \Rightarrow A'(t) = 4at^3 + 3bt^2 + 2ct + d$$

$$(c) A'(1990) \approx 0.0833 \text{ years of age per year}$$

25. (a) $[C] = \frac{a^2 kt}{akt + 1} \Rightarrow$

$$\text{rate of reaction} = \frac{d[C]}{dt} = \frac{(akt + 1)(a^2 k) - (a^2 kt)(ak)}{(akt + 1)^2} = \frac{a^2 k(akt + 1 - akt)}{(akt + 1)^2} = \frac{a^2 k}{(akt + 1)^2}$$

(b) If $x = [C]$, then $a - x = a - \frac{a^2 kt}{akt + 1} = \frac{a^2 kt + a - a^2 kt}{akt + 1} = \frac{a}{akt + 1}$.

So $k(a - x)^2 = k\left(\frac{a}{akt + 1}\right)^2 = \frac{a^2 k}{(akt + 1)^2} = \frac{d[C]}{dt}$ [from part (a)] $= \frac{dx}{dt}$.

26. $\frac{1}{p} = \frac{1}{f} - \frac{1}{q} \Leftrightarrow \frac{1}{p} = \frac{q - f}{fq} \Leftrightarrow p = \frac{fq}{q - f}$. So $\frac{dp}{dq} = \frac{f(q - f) - fq}{(q - f)^2} = -\frac{f^2}{(q - f)^2}$.

27. (a) Using $v = \frac{P}{4\eta l} (R^2 - r^2)$ with $R = 0.01$, $l = 3$, $P = 3000$, and $\eta = 0.027$, we have v as a function of r :

$$v(r) = \frac{3000}{4(0.027)3} (0.01^2 - r^2). \quad v(0) = 0.925 \text{ cm/s}, \quad v(0.005) = 0.694 \text{ cm/s}, \quad v(0.01) = 0.$$

(b) $v(r) = \frac{P}{4\eta l} (R^2 - r^2) \Rightarrow v'(r) = \frac{P}{4\eta l} (-2r) = -\frac{Pr}{2\eta l}$. When $l = 3$, $P = 3000$, and $\eta = 0.027$, we have

$$v'(r) = -\frac{3000r}{2(0.027)3}. \quad v'(0) = 0, \quad v'(0.005) = -92.592 \text{ (cm/s)/cm}, \quad \text{and } v'(0.01) = -185.185 \text{ (cm/s)/cm}.$$

(c) The velocity is greatest where $r = 0$ (at the center) and the velocity is changing most where $r = R = 0.01$ cm (at the edge).

28. (a) (i) $f = \frac{1}{2L} \sqrt{\frac{T}{\rho}} = \left(\frac{1}{2} \sqrt{\frac{T}{\rho}}\right) L^{-1} \Rightarrow \frac{df}{dL} = -\left(\frac{1}{2} \sqrt{\frac{T}{\rho}}\right) L^{-2} = -\frac{1}{2L^2} \sqrt{\frac{T}{\rho}}$

(ii) $f = \frac{1}{2L} \sqrt{\frac{T}{\rho}} = \left(\frac{1}{2L\sqrt{\rho}}\right) T^{1/2} \Rightarrow \frac{df}{dT} = \frac{1}{2} \left(\frac{1}{2L\sqrt{\rho}}\right) T^{-1/2} = \frac{1}{4L\sqrt{T\rho}}$

(iii) $f = \frac{1}{2L} \sqrt{\frac{T}{\rho}} = \left(\frac{\sqrt{T}}{2L}\right) \rho^{-1/2} \Rightarrow \frac{df}{d\rho} = -\frac{1}{2} \left(\frac{\sqrt{T}}{2L}\right) \rho^{-3/2} = -\frac{\sqrt{T}}{4L\rho^{3/2}}$

(b) *Note:* Illustrating tangent lines on the generic figures may help to explain the results.

(i) $\frac{df}{dL} < 0$ and L is decreasing $\Rightarrow f$ is increasing $\Rightarrow$ higher note

(ii) $\frac{df}{dT} > 0$ and T is increasing $\Rightarrow f$ is increasing $\Rightarrow$ higher note

SECTION 3.4 RATES OF CHANGE IN THE NATURAL AND SOCIAL SCIENCES

- (iii) $\frac{df}{d\rho} < 0$ and ρ is increasing $\Rightarrow f$ is decreasing $\Rightarrow$ lower note

29. (a) $C(x) = 2000 + 3x + 0.01x^2 + 0.0002x^3 \Rightarrow C'(x) = 3 + 0.02x + 0.0006x^2$
 (b) $C'(100) = 3 + 0.02(100) + 0.0006(10,000) = 3 + 2 + 6 = \$11/\text{pair}$. $C'(100)$ is the rate at which the cost is increasing as the 100th pair of jeans is produced. It predicts the cost of the 101st pair.
 (c) The cost of manufacturing the 101st pair of jeans is

$$C(101) - C(100) = (2000 + 303 + 102.01 + 206.0602) - (2000 + 300 + 100 + 200) = 11.0702 \approx \$11.07$$

30. (a) $C(x) = 84 + 0.16x - 0.0006x^2 + 0.000003x^3 \Rightarrow C'(x) = 0.16 - 0.0012x + 0.000009x^2 \Rightarrow C'(100) = 0.13$. This is the rate at which the cost is increasing as the 100th item is produced.
 (b) $C(101) - C(100) = 97.13030299 - 97 \approx \0.13 .

31. (a) $A(x) = \frac{p(x)}{x} \Rightarrow A'(x) = \frac{xp'(x) - p(x) \cdot 1}{x^2} = \frac{xp'(x) - p(x)}{x^2}$. $A'(x) > 0 \Rightarrow A(x)$ is increasing; that is, the average productivity increases as the size of the workforce increases.

- (b) $p'(x)$ is greater than the average productivity $\Rightarrow p'(x) > A(x) \Rightarrow p'(x) > \frac{p(x)}{x} \Rightarrow xp'(x) > p(x) \Rightarrow xp'(x) - p(x) > 0 \Rightarrow \frac{xp'(x) - p(x)}{x^2} > 0 \Rightarrow A'(x) > 0$.

32. (a) $S = \frac{dR}{dx} = \frac{(1 + 4x^{0.4})(9.6x^{-0.6}) - (40 + 24x^{0.4})(1.6x^{-0.6})}{(1 + 4x^{0.4})^2}$

$$= \frac{9.6x^{-0.6} + 38.4x^{-0.2} - 64x^{-0.6} - 38.4x^{-0.2}}{(1 + 4x^{0.4})^2} = -\frac{54.4x^{-0.6}}{(1 + 4x^{0.4})^2}$$

At low levels of brightness, R is quite large [$R(0) = 40$] and is quickly decreasing, that is, S is negative with large absolute value. This is to be expected: at low levels of brightness, the eye is more sensitive to slight changes than it is at higher levels of brightness.

33. $PV = nRT \Rightarrow T = \frac{PV}{nR} = \frac{PV}{(10)(0.0821)} = \frac{1}{0.821}(PV)$. Using the Product Rule, we have

$$\frac{dT}{dt} = \frac{1}{0.821} [P(t)V'(t) + V(t)P'(t)] = \frac{1}{0.821} [(8)(-0.15) + (10)(0.10)] \approx -0.2436 \text{ K/min.}$$

34. (a) If $dP/dt = 0$, the population is stable (it is constant).

$$(b) \frac{dP}{dt} = 0 \Rightarrow \beta P = r_0 \left(1 - \frac{P}{P_c}\right) P \Rightarrow \frac{\beta}{r_0} = 1 - \frac{P}{P_c} \Rightarrow \frac{P}{P_c} = 1 - \frac{\beta}{r_0} \Rightarrow P = P_c \left(1 - \frac{\beta}{r_0}\right).$$

If $P_c = 10,000$, $r_0 = 5\% = 0.05$, and $\beta = 4\% = 0.04$, then $P = 10,000 \left(1 - \frac{4}{5}\right) = 2000$.

(c) If $\beta = 0.05$, then $P = 10,000 \left(1 - \frac{5}{5}\right) = 0$. There is no stable population.

35. (a) If the populations are stable, then the growth rates are neither positive nor negative; that is,

$$\frac{dC}{dt} = 0 \text{ and } \frac{dW}{dt} = 0.$$

(b) "The caribou go extinct" means that the population is zero, or mathematically, $C = 0$.

(c) We have the equations $\frac{dC}{dt} = aC - bCW$ and $\frac{dW}{dt} = -cW + dCW$. Let $dC/dt = dW/dt = 0$, $a = 0.05$,

$b = 0.001$, $c = 0.05$, and $d = 0.0001$ to obtain $0.05C - 0.001CW = 0$ (1) and

$-0.05W + 0.0001CW = 0$ (2). Adding 10 times (2) to (1) eliminates the CW -terms and gives us

$0.05C - 0.5W = 0 \Rightarrow C = 10W$. Substituting $C = 10W$ into (1) results in

$$0.05(10W) - 0.001(10W)W = 0 \Leftrightarrow 0.5W - 0.01W^2 = 0 \Leftrightarrow 50W - W^2 = 0 \Leftrightarrow$$

$$W(50 - W) = 0 \Leftrightarrow W = 0 \text{ or } 50. \text{ Since } C = 10W, C = 0 \text{ or } 500. \text{ Thus, the population pairs } (C, W)$$

that lead to stable populations are $(0, 0)$ and $(500, 50)$. So it is possible for the two species to live in harmony.

3.5 Derivatives of Trigonometric Functions

$$1. f(x) = x - 3 \sin x \Rightarrow f'(x) = 1 - 3 \cos x$$

$$2. f(x) = x \sin x \Rightarrow f'(x) = x \cdot \cos x + (\sin x) \cdot 1 = x \cos x + \sin x$$

$$3. y = \sin x + 10 \tan x \Rightarrow y' = \cos x + 10 \sec^2 x$$

$$4. y = 2 \csc x + 5 \cos x \Rightarrow y' = -2 \csc x \cot x - 5 \sin x$$

$$5. g(t) = t^3 \cos t \Rightarrow g'(t) = t^3(-\sin t) + (\cos t) \cdot 3t^2 = 3t^2 \cos t - t^3 \sin t \text{ or } t^2(3 \cos t - t \sin t)$$

$$6. g(t) = 4 \sec t + \tan t \Rightarrow g'(t) = 4 \sec t \tan t + \sec^2 t$$

$$7. h(\theta) = \theta \csc \theta - \cot \theta \Rightarrow h'(\theta) = \theta(-\csc \theta \cot \theta) + (\csc \theta) \cdot 1 - (-\csc^2 \theta) = \csc \theta - \theta \csc \theta \cot \theta + \csc^2 \theta$$

$$8. y = u(a \cos u + b \cot u) \Rightarrow$$

$$y' = u(-a \sin u - b \csc^2 u) + (a \cos u + b \cot u) \cdot 1 = a \cos u + b \cot u - au \sin u - bu \csc^2 u$$

$$9. y = \frac{x}{\cos x} \Rightarrow y' = \frac{(\cos x)(1) - (x)(-\sin x)}{(\cos x)^2} = \frac{\cos x + x \sin x}{\cos^2 x}$$

$$10. y = \frac{1 + \sin x}{x + \cos x} \Rightarrow$$

$$y' = \frac{(x + \cos x)(\cos x) - (1 + \sin x)(1 - \sin x)}{(x + \cos x)^2} = \frac{x \cos x + \cos^2 x - (1 - \sin^2 x)}{(x + \cos x)^2}$$

$$= \frac{x \cos x + \cos^2 x - (\cos^2 x)}{(x + \cos x)^2} = \frac{x \cos x}{(x + \cos x)^2}$$

$$11. f(\theta) = \frac{\sec \theta}{1 + \sec \theta} \Rightarrow$$

$$f'(\theta) = \frac{(1 + \sec \theta)(\sec \theta \tan \theta) - (\sec \theta)(\sec \theta \tan \theta)}{(1 + \sec \theta)^2} = \frac{(\sec \theta \tan \theta)[(1 + \sec \theta) - \sec \theta]}{(1 + \sec \theta)^2} = \frac{\sec \theta \tan \theta}{(1 + \sec \theta)^2}$$

$$12. y = \frac{\tan x - 1}{\sec x} \Rightarrow$$

$$\frac{dy}{dx} = \frac{\sec x \sec^2 x - (\tan x - 1) \sec x \tan x}{\sec^2 x} = \frac{\sec x (\sec^2 x - \tan^2 x + \tan x)}{\sec^2 x} = \frac{1 + \tan x}{\sec x}$$

Another method: Simplify y first: $y = \sin x - \cos x \Rightarrow y' = \cos x + \sin x$.

$$13. y = \frac{\sin x}{x^2} \Rightarrow y' = \frac{x^2 \cos x - (\sin x)(2x)}{(x^2)^2} = \frac{x(x \cos x - 2 \sin x)}{x^4} = \frac{x \cos x - 2 \sin x}{x^3}$$

$$14. y = \csc \theta (\theta + \cot \theta) \Rightarrow$$

$$y' = \csc \theta (1 - \csc^2 \theta) + (\theta + \cot \theta)(-\csc \theta \cot \theta) = \csc \theta (1 - \csc^2 \theta - \theta \cot \theta - \cot^2 \theta)$$

$$= \csc \theta (-\cot^2 \theta - \theta \cot \theta - \cot^2 \theta) \quad [1 + \cot^2 \theta = \csc^2 \theta]$$

$$= \csc \theta (-\theta \cot \theta - 2 \cot^2 \theta) = -\csc \theta \cot \theta (\theta + 2 \cot \theta)$$

$$15. y = \sec \theta \tan \theta \Rightarrow y' = \sec \theta (\sec^2 \theta) + \tan \theta (\sec \theta \tan \theta) = \sec \theta (\sec^2 \theta + \tan^2 \theta)$$

Using the identity $1 + \tan^2 \theta = \sec^2 \theta$, we can write alternative forms of the answer as

$$\sec \theta (1 + 2 \tan^2 \theta) \quad \text{or} \quad \sec \theta (2 \sec^2 \theta - 1)$$

$$16. \text{Recall that if } y = fgh, \text{ then } y' = f'gh + fg'h + fgh'. y = x \sin x \cos x \Rightarrow$$

$$\frac{dy}{dx} = \sin x \cos x + x \cos x \cos x + x \sin x (-\sin x) = \sin x \cos x + x \cos^2 x - x \sin^2 x$$

$$17. \frac{d}{dx} (\csc x) = \frac{d}{dx} \left(\frac{1}{\sin x} \right) = \frac{(\sin x)(0) - 1(\cos x)}{\sin^2 x} = \frac{-\cos x}{\sin^2 x} = -\frac{1}{\sin x} \cdot \frac{\cos x}{\sin x} = -\csc x \cot x$$

$$18. \frac{d}{dx} (\sec x) = \frac{d}{dx} \left(\frac{1}{\cos x} \right) = \frac{(\cos x)(0) - 1(-\sin x)}{\cos^2 x} = \frac{\sin x}{\cos^2 x} = \frac{1}{\cos x} \cdot \frac{\sin x}{\cos x} = \sec x \tan x$$

$$19. \frac{d}{dx} (\cot x) = \frac{d}{dx} \left(\frac{\cos x}{\sin x} \right) = \frac{(\sin x)(-\sin x) - (\cos x)(\cos x)}{\sin^2 x} = -\frac{\sin^2 x + \cos^2 x}{\sin^2 x} = -\frac{1}{\sin^2 x} = -\csc^2 x$$

$$20. f(x) = \cos x \Rightarrow$$

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{\cos(x+h) - \cos x}{h} = \lim_{h \rightarrow 0} \frac{\cos x \cos h - \sin x \sin h - \cos x}{h}$$

$$= \lim_{h \rightarrow 0} \left(\cos x \frac{\cos h - 1}{h} - \sin x \frac{\sin h}{h} \right) = \cos x \lim_{h \rightarrow 0} \frac{\cos h - 1}{h} - \sin x \lim_{h \rightarrow 0} \frac{\sin h}{h}$$

$$= (\cos x)(0) - (\sin x)(1) = -\sin x$$

$$21. y = \tan x \Rightarrow y' = \sec^2 x \Rightarrow \text{the slope of the tangent line at } \left(\frac{\pi}{4}, 1 \right) \text{ is } \sec^2 \frac{\pi}{4} = (\sqrt{2})^2 = 2 \text{ and an equation of the tangent line is } y - 1 = 2(x - \frac{\pi}{4}) \text{ or } y = 2x + 1 - \frac{\pi}{2}.$$

$$22. y = (1+x) \cos x \Rightarrow y' = (1+x)(-\sin x) + \cos x \cdot 1. \text{ At } (0, 1), y' = 1, \text{ and an equation of the tangent line is } y - 1 = 1(x - 0), \text{ or } y = x + 1.$$

$$23. y = x + \cos x \Rightarrow y' = 1 - \sin x. \text{ At } (0, 1), y' = 1, \text{ and an equation of the tangent line is } y - 1 = 1(x - 0), \text{ or } y = x + 1.$$

24. $y = \frac{1}{\sin x + \cos x} \Rightarrow y' = -\frac{\cos x - \sin x}{(\sin x + \cos x)^2}$ [Reciprocal Rule]. At $(0, 1)$, $y' = -\frac{1-0}{(0+1)^2} = -1$, and an equation of the tangent line is $y - 1 = -1(x - 0)$, or $y = -x + 1$.

25. (a) $y = x \cos x \Rightarrow y' = x(-\sin x) + \cos x(1) = \cos x - x \sin x$.

So the slope of the tangent at the point $(\pi, -\pi)$ is

$\cos \pi - \pi \sin \pi = -1 - \pi(0) = -1$, and an equation is

$y + \pi = -(x - \pi)$ or $y = -x$.

(b)

26. (a) $y = \sec x - 2 \cos x \Rightarrow y' = \sec x \tan x + 2 \sin x \Rightarrow$

the slope of the tangent line at $(\frac{\pi}{3}, 1)$ is

$\sec \frac{\pi}{3} \tan \frac{\pi}{3} + 2 \sin \frac{\pi}{3} = 2 \cdot \sqrt{3} + 2 \cdot \frac{\sqrt{3}}{2} = 3\sqrt{3}$ and an equation is

$y - 1 = 3\sqrt{3}(x - \frac{\pi}{3})$ or $y = 3\sqrt{3}x + 1 - \pi\sqrt{3}$.

(b)

27. (a) $f(x) = 2x + \cot x \Rightarrow f'(x) = 2 - \csc^2 x$

(b)

Notice that $f'(x) = 0$ when f has a horizontal tangent.

f' is positive when f is increasing and f' is negative when f is decreasing. Also, $f'(x)$ is large negative when the graph of f is steep.

28. (a) $f(x) = \sqrt{x} \sin x \Rightarrow f'(x) = \sqrt{x} \cos x + (\sin x)\left(\frac{1}{2}x^{-1/2}\right) = \sqrt{x} \cos x + \frac{\sin x}{2\sqrt{x}}$

(b)

Notice that $f'(x) = 0$ when f has a horizontal tangent.

f' is positive when f is increasing and f' is negative when f is decreasing.

29. $f(x) = x + 2 \sin x$ has a horizontal tangent when $f'(x) = 0 \Leftrightarrow 1 + 2 \cos x = 0 \Leftrightarrow \cos x = -\frac{1}{2} \Leftrightarrow x = \frac{2\pi}{3} + 2\pi n$ or $\frac{4\pi}{3} + 2\pi n$, where n is an integer. Note that $\frac{4\pi}{3}$ and $\frac{2\pi}{3}$ are $\pm \frac{\pi}{3}$ units from π . This allows us to write the solutions in the more compact equivalent form $(2n + 1)\pi \pm \frac{\pi}{3}$, n an integer.

$$30. y = \frac{\cos x}{2 + \sin x} \Rightarrow$$

$$y' = \frac{(2 + \sin x)(-\sin x) - \cos x \cos x}{(2 + \sin x)^2} = \frac{-2\sin x - \sin^2 x - \cos^2 x}{(2 + \sin x)^2} = \frac{-2\sin x - 1}{(2 + \sin x)^2} = 0 \text{ when}$$

$$-2\sin x - 1 = 0 \Leftrightarrow \sin x = -\frac{1}{2} \Leftrightarrow x = \frac{11\pi}{6} + 2\pi n \text{ or } x = \frac{7\pi}{6} + 2\pi n, n \text{ an integer. So } y = \frac{1}{\sqrt{3}} \text{ or}$$

$y = -\frac{1}{\sqrt{3}}$ and the points on the curve with horizontal tangents are: $\left(\frac{11\pi}{6} + 2\pi n, \frac{1}{\sqrt{3}}\right), \left(\frac{7\pi}{6} + 2\pi n, -\frac{1}{\sqrt{3}}\right)$, n an integer.

$$31. (a) x(t) = 8 \sin t \Rightarrow v(t) = x'(t) = 8 \cos t$$

(b) The mass at time $t = \frac{2\pi}{3}$ has position $x\left(\frac{2\pi}{3}\right) = 8 \sin \frac{2\pi}{3} = 8\left(\frac{\sqrt{3}}{2}\right) = 4\sqrt{3}$ and velocity

$$v\left(\frac{2\pi}{3}\right) = 8 \cos \frac{2\pi}{3} = 8\left(-\frac{1}{2}\right) = -4. \text{ Since } v\left(\frac{2\pi}{3}\right) < 0, \text{ the particle is moving to the left.}$$

$$32. (a) s(t) = 2 \cos t + 3 \sin t \Rightarrow v(t) = -2 \sin t + 3 \cos t$$

(b)

(c) $s = 0 \Rightarrow t_2 \approx 2.55$. So the mass passes through the equilibrium position for the first time when $t \approx 2.55$ s.

(d) $v = 0 \Rightarrow t_1 \approx 0.98, s(t_1) \approx 3.61$ cm. So the mass travels a maximum of about 3.6 cm (upward and downward) from its equilibrium position.

(e) The speed $|v|$ is greatest when $s = 0$; that is, when $t = t_2 + n\pi, n$ a positive integer.

33.

From the diagram we can see that $\sin \theta = x/10 \Leftrightarrow x = 10 \sin \theta$. We want to find the rate of change of x with respect to θ ; that is, $dx/d\theta$. Taking the derivative of the above expression, $dx/d\theta = 10(\cos \theta)$. So when $\theta = \frac{\pi}{3}$,

$$dx/d\theta = 10 \cos \frac{\pi}{3} = 10\left(\frac{1}{2}\right) = 5 \text{ ft/rad}$$

$$34. (a) F = \frac{\mu W}{\mu \sin \theta + \cos \theta} \Rightarrow \frac{dF}{d\theta} = \frac{(\mu \sin \theta + \cos \theta)(0) - \mu W(\mu \cos \theta - \sin \theta)}{(\mu \sin \theta + \cos \theta)^2} = \frac{\mu W(\sin \theta - \mu \cos \theta)}{(\mu \sin \theta + \cos \theta)^2}$$

$$(b) \frac{dF}{d\theta} = 0 \Rightarrow \mu W(\sin \theta - \mu \cos \theta) = 0 \Rightarrow \sin \theta = \mu \cos \theta \Rightarrow \tan \theta = \mu \Rightarrow \theta = \tan^{-1} \mu$$

(c)

From the graph of $F = \frac{0.6(50)}{0.6 \sin \theta + \cos \theta}$ for $0 \leq \theta \leq 1$, we see that

$$\frac{dF}{d\theta} = 0 \Rightarrow \theta \approx 0.54. \text{ Checking this with part (b) and } \mu = 0.6,$$

we calculate $\theta = \tan^{-1} 0.6 \approx 0.54$. So the value from the graph is consistent with the value in part (b).

$$\begin{aligned}
 35. \lim_{x \rightarrow 0} \frac{\sin 3x}{x} &= \lim_{x \rightarrow 0} \frac{3 \sin 3x}{3x} \quad [\text{multiply numerator and denominator by 3}] \\
 &= 3 \lim_{3x \rightarrow 0} \frac{\sin 3x}{3x} \quad [\text{as } x \rightarrow 0, 3x \rightarrow 0] \\
 &= 3 \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} \quad [\text{let } \theta = 3x] \\
 &= 3(1) \quad [\text{Equation 2}] \\
 &= 3
 \end{aligned}$$

$$\begin{aligned}
 36. \lim_{x \rightarrow 0} \frac{\sin 4x}{\sin 6x} &= \lim_{x \rightarrow 0} \left(\frac{\sin 4x}{x} \cdot \frac{x}{\sin 6x} \right) = \lim_{x \rightarrow 0} \frac{4 \sin 4x}{4x} \cdot \lim_{x \rightarrow 0} \frac{6x}{6 \sin 6x} \\
 &= 4 \lim_{x \rightarrow 0} \frac{\sin 4x}{4x} \cdot \frac{1}{6} \lim_{x \rightarrow 0} \frac{6x}{\sin 6x} = 4(1) \cdot \frac{1}{6}(1) = \frac{2}{3}
 \end{aligned}$$

$$\begin{aligned}
 37. \lim_{t \rightarrow 0} \frac{\tan 6t}{\sin 2t} &= \lim_{t \rightarrow 0} \left(\frac{\sin 6t}{t} \cdot \frac{1}{\cos 6t} \cdot \frac{t}{\sin 2t} \right) = \lim_{t \rightarrow 0} \frac{6 \sin 6t}{6t} \cdot \lim_{t \rightarrow 0} \frac{1}{\cos 6t} \cdot \lim_{t \rightarrow 0} \frac{2t}{2 \sin 2t} \\
 &= 6 \lim_{t \rightarrow 0} \frac{\sin 6t}{6t} \cdot \lim_{t \rightarrow 0} \frac{1}{\cos 6t} \cdot \frac{1}{2} \lim_{t \rightarrow 0} \frac{2t}{\sin 2t} = 6(1) \cdot \frac{1}{1} \cdot \frac{1}{2}(1) = 3
 \end{aligned}$$

$$38. \lim_{\theta \rightarrow 0} \frac{\cos \theta - 1}{\sin \theta} = \lim_{\theta \rightarrow 0} \frac{\frac{\cos \theta - 1}{\theta}}{\frac{\sin \theta}{\theta}} = \frac{\lim_{\theta \rightarrow 0} \frac{\cos \theta - 1}{\theta}}{\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta}} = \frac{0}{1} = 0$$

$$39. \lim_{\theta \rightarrow 0} \frac{\sin(\cos \theta)}{\sec \theta} = \frac{\sin\left(\lim_{\theta \rightarrow 0} \cos \theta\right)}{\lim_{\theta \rightarrow 0} \sec \theta} = \frac{\sin 1}{1} = \sin 1$$

$$\begin{aligned}
 40. \lim_{t \rightarrow 0} \frac{\sin^2 3t}{t^2} &= \lim_{t \rightarrow 0} \left(\frac{\sin 3t}{t} \cdot \frac{\sin 3t}{t} \right) = \lim_{t \rightarrow 0} \frac{\sin 3t}{t} \cdot \lim_{t \rightarrow 0} \frac{\sin 3t}{t} \\
 &= \left(\lim_{t \rightarrow 0} \frac{\sin 3t}{t} \right)^2 = \left(3 \lim_{t \rightarrow 0} \frac{\sin 3t}{3t} \right)^2 = (3 \cdot 1)^2 = 9
 \end{aligned}$$

$$\begin{aligned}
 41. \lim_{x \rightarrow 0} \frac{\cot 2x}{\csc x} &= \lim_{x \rightarrow 0} \frac{\cos 2x \sin x}{\sin 2x} = \lim_{x \rightarrow 0} \cos 2x \left[\frac{(\sin x)/x}{(\sin 2x)/x} \right] = \lim_{x \rightarrow 0} \cos 2x \left[\frac{\lim_{x \rightarrow 0} [(\sin x)/x]}{2 \lim_{x \rightarrow 0} [(\sin 2x)/2x]} \right] \\
 &= 1 \cdot \frac{1}{2 \cdot 1} = \frac{1}{2}
 \end{aligned}$$

$$\begin{aligned}
 42. \lim_{x \rightarrow \pi/4} \frac{\sin x - \cos x}{\cos 2x} &= \lim_{x \rightarrow \pi/4} \frac{\sin x - \cos x}{\cos^2 x - \sin^2 x} = \lim_{x \rightarrow \pi/4} \frac{\sin x - \cos x}{(\cos x + \sin x)(\cos x - \sin x)} \\
 &= \lim_{x \rightarrow \pi/4} \frac{-1}{\cos x + \sin x} = \frac{-1}{\cos \frac{\pi}{4} + \sin \frac{\pi}{4}} = \frac{-1}{\sqrt{2}}
 \end{aligned}$$

43. Divide numerator and denominator by θ . ($\sin \theta$ also works.)

$$\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta + \tan \theta} = \lim_{\theta \rightarrow 0} \frac{\frac{\sin \theta}{\theta}}{1 + \frac{\sin \theta}{\theta} \cdot \frac{1}{\cos \theta}} = \frac{\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta}}{1 + \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} \lim_{\theta \rightarrow 0} \frac{1}{\cos \theta}} = \frac{1}{1 + 1 \cdot 1} = \frac{1}{2}$$

$$44. \lim_{x \rightarrow 1} \frac{\sin(x-1)}{x^2 + x - 2} = \lim_{x \rightarrow 1} \frac{\sin(x-1)}{(x+2)(x-1)} = \lim_{x \rightarrow 1} \frac{1}{x+2} \lim_{x \rightarrow 1} \frac{\sin(x-1)}{x-1} = \frac{1}{3} \cdot 1 = \frac{1}{3}$$

45. (a) $\frac{d}{dx} \tan x = \frac{d}{dx} \frac{\sin x}{\cos x} \Rightarrow \sec^2 x = \frac{\cos x \cos x - \sin x (-\sin x)}{\cos^2 x} = \frac{\cos^2 x + \sin^2 x}{\cos^2 x}$. So $\sec^2 x = \frac{1}{\cos^2 x}$.
- (b) $\frac{d}{dx} \sec x = \frac{d}{dx} \frac{1}{\cos x} \Rightarrow \sec x \tan x = \frac{(\cos x)(0) - 1(-\sin x)}{\cos^2 x}$. So $\sec x \tan x = \frac{\sin x}{\cos^2 x}$.
- (c) $\frac{d}{dx} (\sin x + \cos x) = \frac{d}{dx} \frac{1 + \cot x}{\csc x} \Rightarrow$

$$\cos x - \sin x = \frac{\csc x (-\csc^2 x) - (1 + \cot x)(-\csc x \cot x)}{\csc^2 x} = \frac{\csc x [-\csc^2 x + (1 + \cot x) \cot x]}{\csc^2 x}$$

$$= \frac{-\csc^2 x + \cot^2 x + \cot x}{\csc x} = \frac{-1 + \cot x}{\csc x}$$
 So $\cos x - \sin x = \frac{\cot x - 1}{\csc x}$.

46. Let $|PR| = x$. Then we get the following formulas for r and h in terms of θ and x :

$$\sin \frac{\theta}{2} = \frac{r}{x} \Rightarrow r = x \sin \frac{\theta}{2} \text{ and } \cos \frac{\theta}{2} = \frac{h}{x} \Rightarrow h = x \cos \frac{\theta}{2}.$$

Now $A(\theta) = \frac{1}{2}\pi r^2$ and $B(\theta) = \frac{1}{2}(2r)h = rh$. So

$$\begin{aligned} \lim_{\theta \rightarrow 0^+} \frac{A(\theta)}{B(\theta)} &= \lim_{\theta \rightarrow 0^+} \frac{\frac{1}{2}\pi r^2}{rh} = \frac{1}{2}\pi \lim_{\theta \rightarrow 0^+} \frac{r}{h} = \frac{1}{2}\pi \lim_{\theta \rightarrow 0^+} \frac{x \sin(\theta/2)}{x \cos(\theta/2)} \\ &= \frac{1}{2}\pi \lim_{\theta \rightarrow 0^+} \tan(\theta/2) = 0. \end{aligned}$$

47. By the definition of radian measure, $s = r\theta$, where r is the radius of the circle.

By drawing the bisector of the angle θ , we can see that $\sin \frac{\theta}{2} = \frac{d/2}{r} \Rightarrow d = 2r \sin \frac{\theta}{2}$.

So $\lim_{\theta \rightarrow 0^+} \frac{s}{d} = \lim_{\theta \rightarrow 0^+} \frac{r\theta}{2r \sin(\theta/2)} = \lim_{\theta \rightarrow 0^+} \frac{2 \cdot (\theta/2)}{2 \sin(\theta/2)} = \lim_{\theta \rightarrow 0} \frac{\theta/2}{\sin(\theta/2)} = 1$. [This is just the reciprocal of the limit $\lim_{x \rightarrow 0} \frac{\sin x}{x} = 1$ combined with the fact that as $\theta \rightarrow 0$, $\frac{\theta}{2} \rightarrow 0$ also.]

3.6 The Chain Rule

- Let $u = g(x) = 4x$ and $y = f(u) = \sin u$. Then $\frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx} = (\cos u)(4) = 4 \cos 4x$.
- Let $u = g(x) = 4 + 3x$ and $y = f(u) = \sqrt{u} = u^{1/2}$. Then $\frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx} = \frac{1}{2}u^{-1/2}(3) = \frac{3}{2\sqrt{u}} = \frac{3}{2\sqrt{4+3x}}$.
- Let $u = g(x) = 1 - x^2$ and $y = f(u) = u^{10}$. Then $\frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx} = (10u^9)(-2x) = -20x(1 - x^2)^9$.
- Let $u = g(x) = \sin x$ and $y = f(u) = \tan u$. Then $\frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx} = (\sec^2 u)(\cos x) = \sec^2(\sin x) \cdot \cos x$, or equivalently, $[\sec(\sin x)]^2 \cos x$.
- Let $u = g(x) = \sin x$ and $y = f(u) = \sqrt{u}$. Then $\frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx} = \frac{1}{2}u^{-1/2} \cos x = \frac{\cos x}{2\sqrt{u}} = \frac{\cos x}{2\sqrt{\sin x}}$.
- Let $u = g(x) = \sqrt{x}$ and $y = f(u) = \sin u$. Then $\frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx} = (\cos u)\left(\frac{1}{2}x^{-1/2}\right) = \frac{\cos u}{2\sqrt{x}} = \frac{\cos \sqrt{x}}{2\sqrt{x}}$.
- $F(x) = (x^3 + 4x)^7 \Rightarrow F'(x) = 7(x^3 + 4x)^6(3x^2 + 4)$ [or $7x^6(x^2 + 4)^6(3x^2 + 4)$]
- $F(x) = (x^2 - x + 1)^3 \Rightarrow F'(x) = 3(x^2 - x + 1)^2(2x - 1)$

9. $F(x) = \sqrt[4]{1+2x+x^3} = (1+2x+x^3)^{1/4} \Rightarrow$
 $F'(x) = \frac{1}{4}(1+2x+x^3)^{-3/4} \cdot \frac{d}{dx}(1+2x+x^3) = \frac{1}{4(1+2x+x^3)^{3/4}} \cdot (2+3x^2)$
 $= \frac{2+3x^2}{4(1+2x+x^3)^{3/4}} = \frac{2+3x^2}{4\sqrt[4]{(1+2x+x^3)^3}}$
10. $f(x) = (1+x^4)^{2/3} \Rightarrow f'(x) = \frac{2}{3}(1+x^4)^{-1/3}(4x^3) = \frac{8x^3}{3\sqrt[3]{1+x^4}}$
11. $g(t) = \frac{1}{(t^4+1)^3} = (t^4+1)^{-3} \Rightarrow g'(t) = -3(t^4+1)^{-4}(4t^3) = -12t^3(t^4+1)^{-4} = \frac{-12t^3}{(t^4+1)^4}$
12. $f(t) = \sqrt[3]{1+\tan t} = (1+\tan t)^{1/3} \Rightarrow f'(t) = \frac{1}{3}(1+\tan t)^{-2/3} \sec^2 t = \frac{\sec^2 t}{3\sqrt[3]{(1+\tan t)^2}}$
13. $y = \cos(a^3+x^3) \Rightarrow y' = -\sin(a^3+x^3) \cdot 3x^2$ [a^3 is just a constant] $= -3x^2 \sin(a^3+x^3)$
14. $y = a^3 + \cos^3 x \Rightarrow y' = 3(\cos x)^2(-\sin x)$ [a^3 is just a constant] $= -3 \sin x \cos^2 x$
15. $y = \cot(x/2) \Rightarrow y' = -\csc^2(x/2) \cdot \frac{1}{2} = -\frac{1}{2} \csc^2(x/2)$
16. $y = 4 \sec 5x \Rightarrow y' = 4 \sec 5x \tan 5x(5) = 20 \sec 5x \tan 5x$
17. $g(x) = (1+4x)^5(3+x-x^2)^8 \Rightarrow$
 $g'(x) = (1+4x)^5 \cdot 8(3+x-x^2)^7(1-2x) + (3+x-x^2)^8 \cdot 5(1+4x)^4 \cdot 4$
 $= 4(1+4x)^4(3+x-x^2)^7 [2(1+4x)(1-2x) + 5(3+x-x^2)]$
 $= 4(1+4x)^4(3+x-x^2)^7 [(2+4x-16x^2) + (15+5x-5x^2)]$
 $= 4(1+4x)^4(3+x-x^2)^7 (17+9x-21x^2)$
18. $h(t) = (t^4-1)^3(t^3+1)^4 \Rightarrow$
 $h'(t) = (t^4-1)^3 \cdot 4(t^3+1)^3(3t^2) + (t^3+1)^4 \cdot 3(t^4-1)^2(4t^3)$
 $= 12t^2(t^4-1)^2(t^3+1)^3 [(t^4-1) + t(t^3+1)] = 12t^2(t^4-1)^2(t^3+1)^3 (2t^4+t-1)$
19. $y = (2x-5)^4(8x^2-5)^{-3} \Rightarrow$
 $y' = 4(2x-5)^3(2)(8x^2-5)^{-3} + (2x-5)^4(-3)(8x^2-5)^{-4}(16x)$
 $= 8(2x-5)^3(8x^2-5)^{-3} - 48x(2x-5)^4(8x^2-5)^{-4}$
 [This simplifies to $8(2x-5)^3(8x^2-5)^{-4}(-4x^2+30x-5)$.]
20. $y = (x^2+1)(x^2+2)^{1/3} \Rightarrow$
 $y' = 2x(x^2+2)^{1/3} + (x^2+1)\left(\frac{1}{3}\right)(x^2+2)^{-2/3}(2x) = 2x(x^2+2)^{1/3} \left[1 + \frac{x^2+1}{3(x^2+2)}\right]$
21. $y = x^3 \cos nx \Rightarrow y' = x^3(-\sin nx)(n) + \cos nx (3x^2) = x^2(3 \cos nx - nx \sin nx)$
22. $y = x \sin \sqrt{x} \Rightarrow y' = x \cos \sqrt{x} \cdot \frac{1}{2}x^{-1/2} + \sin \sqrt{x} \cdot 1 = \frac{1}{2}\sqrt{x} \cos \sqrt{x} + \sin \sqrt{x}$
23. $y = \sin(x \cos x) \Rightarrow y' = \cos(x \cos x) \cdot [x(-\sin x) + \cos x \cdot 1] = (\cos x - x \sin x) \cos(x \cos x)$

$$24. f(x) = \frac{x}{\sqrt{7-3x}} \Rightarrow$$

$$f'(x) = \frac{\sqrt{7-3x}(1) - x \cdot \frac{1}{2}(7-3x)^{-1/2} \cdot (-3)}{(\sqrt{7-3x})^2} = \frac{\sqrt{7-3x} + \frac{3x}{2\sqrt{7-3x}}}{(7-3x)^1}$$

$$= \frac{2(7-3x) + 3x}{2(7-3x)^{3/2}} = \frac{14-3x}{2(7-3x)^{3/2}}$$

$$25. F(z) = \sqrt{\frac{z-1}{z+1}} = \left(\frac{z-1}{z+1}\right)^{1/2} \Rightarrow$$

$$F'(z) = \frac{1}{2} \left(\frac{z-1}{z+1}\right)^{-1/2} \cdot \frac{d}{dz} \left(\frac{z-1}{z+1}\right) = \frac{1}{2} \left(\frac{z+1}{z-1}\right)^{1/2} \cdot \frac{(z+1)(1) - (z-1)(1)}{(z+1)^2}$$

$$= \frac{1}{2} \frac{(z+1)^{1/2}}{(z-1)^{1/2}} \cdot \frac{z+1-z+1}{(z+1)^2} = \frac{1}{2} \frac{(z+1)^{1/2}}{(z-1)^{1/2}} \cdot \frac{2}{(z+1)^2} = \frac{1}{(z-1)^{1/2}(z+1)^{3/2}}$$

$$26. G(y) = \frac{(y-1)^4}{(y^2+2y)^5} \Rightarrow$$

$$G'(y) = \frac{(y^2+2y)^5 \cdot 4(y-1)^3 \cdot 1 - (y-1)^4 \cdot 5(y^2+2y)^4(2y+2)}{[(y^2+2y)^5]^2}$$

$$= \frac{2(y^2+2y)^4(y-1)^3[2(y^2+2y) - 5(y-1)(y+1)]}{(y^2+2y)^{10}}$$

$$= \frac{2(y-1)^3[(2y^2+4y) + (-5y^2+5)]}{(y^2+2y)^6} = \frac{2(y-1)^3(-3y^2+4y+5)}{(y^2+2y)^6}$$

$$27. y = \frac{r}{\sqrt{r^2+1}} \Rightarrow$$

$$y' = \frac{\sqrt{r^2+1}(1) - r \cdot \frac{1}{2}(r^2+1)^{-1/2}(2r)}{(\sqrt{r^2+1})^2} = \frac{\sqrt{r^2+1} - \frac{r^2}{\sqrt{r^2+1}}}{(\sqrt{r^2+1})^2} = \frac{\frac{\sqrt{r^2+1}\sqrt{r^2+1} - r^2}{\sqrt{r^2+1}}}{(\sqrt{r^2+1})^2}$$

$$= \frac{(r^2+1) - r^2}{(\sqrt{r^2+1})^3} = \frac{1}{(r^2+1)^{3/2}} \text{ or } (r^2+1)^{-3/2}$$

Another solution: Write y as a product and make use of the Product Rule. $y = r(r^2+1)^{-1/2} \Rightarrow$

$$y' = r \cdot -\frac{1}{2}(r^2+1)^{-3/2}(2r) + (r^2+1)^{-1/2} \cdot 1$$

$$= (r^2+1)^{-3/2}[-r^2 + (r^2+1)^1] = (r^2+1)^{-3/2}(1) = (r^2+1)^{-3/2}$$

The step that students usually have trouble with is factoring out $(r^2+1)^{-3/2}$. But this is no different than factoring out x^2 from $x^2 + x^5$; that is, we are just factoring out a factor with the *smallest* exponent that appears on it. In this case, $-\frac{3}{2}$ is smaller than $-\frac{1}{2}$.

$$28. y = \frac{\cos \pi x}{\sin \pi x + \cos \pi x} \Rightarrow$$

$$y' = \frac{(\sin \pi x + \cos \pi x)(-\pi \sin \pi x) - (\cos \pi x)(\pi \cos \pi x - \pi \sin \pi x)}{(\sin \pi x + \cos \pi x)^2}$$

$$= \frac{-\pi \sin^2 \pi x - \pi \sin \pi x \cos \pi x - \pi \cos^2 \pi x + \pi \sin \pi x \cos \pi x}{(\sin \pi x + \cos \pi x)^2}$$

$$= \frac{-\pi(\sin^2 \pi x + \cos^2 \pi x)}{(\sin \pi x + \cos \pi x)^2} = \frac{-\pi}{(\sin \pi x + \cos \pi x)^2} \text{ or } \frac{-\pi}{1 + 2 \sin \pi x \cos \pi x}$$

$$29. y = \tan(\cos x) \Rightarrow y' = \sec^2(\cos x) \cdot (-\sin x) = -\sin x \sec^2(\cos x)$$

$$30. y = \frac{\sin^2 x}{\cos x} \Rightarrow$$

$$y' = \frac{\cos x (2 \sin x \cos x) - \sin^2 x (-\sin x)}{\cos^2 x} = \frac{\sin x (2 \cos^2 x + \sin^2 x)}{\cos^2 x} = \frac{\sin x (1 + \cos^2 x)}{\cos^2 x}$$

$$= \sin x (1 + \sec^2 x)$$

$$\text{Another method: } y = \tan x \sin x \Rightarrow y' = \sec^2 x \sin x + \tan x \cos x = \sec^2 x \sin x + \sin x$$

$$31. y = \sin \sqrt{1+x^2} \Rightarrow y' = \cos \sqrt{1+x^2} \cdot \frac{1}{2}(1+x^2)^{-1/2} \cdot 2x = (x \cos \sqrt{1+x^2}) / \sqrt{1+x^2}$$

$$32. y = \tan^2(3\theta) = (\tan 3\theta)^2 \Rightarrow y' = 2(\tan 3\theta) \cdot \frac{d}{d\theta}(\tan 3\theta) = 2 \tan 3\theta \cdot \sec^2 3\theta \cdot 3 = 6 \tan 3\theta \sec^2 3\theta$$

$$33. y = (1 + \cos^2 x)^6 \Rightarrow y' = 6(1 + \cos^2 x)^5 \cdot 2 \cos x (-\sin x) = -12 \cos x \sin x (1 + \cos^2 x)^5$$

$$34. y = x \sin \frac{1}{x} \Rightarrow y' = \sin \frac{1}{x} + x \cos \frac{1}{x} \left(-\frac{1}{x^2}\right) = \sin \frac{1}{x} - \frac{1}{x} \cos \frac{1}{x}$$

$$35. y = \sec^2 x + \tan^2 x = (\sec x)^2 + (\tan x)^2 \Rightarrow$$

$$y' = 2(\sec x)(\sec x \tan x) + 2(\tan x)(\sec^2 x) = 2 \sec^2 x \tan x + 2 \sec^2 x \tan x = 4 \sec^2 x \tan x$$

$$36. y = \cot(x^2) + \cot^2 x = \cot(x^2) + (\cot x)^2 \Rightarrow$$

$$y' = -\csc^2(x^2) \cdot 2x + 2(\cot x)^1 (-\csc^2 x) = -2x \csc^2(x^2) - 2 \cot x \csc^2 x$$

$$37. y = \cot^2(\sin \theta) = [\cot(\sin \theta)]^2 \Rightarrow$$

$$y' = 2[\cot(\sin \theta)] \cdot \frac{d}{d\theta}[\cot(\sin \theta)] = 2 \cot(\sin \theta) \cdot [-\csc^2(\sin \theta) \cdot \cos \theta] = -2 \cos \theta \cot(\sin \theta) \csc^2(\sin \theta)$$

$$38. y = \sin(\sin(\sin x)) \Rightarrow y' = \cos(\sin(\sin x)) \frac{d}{dx}(\sin(\sin x)) = \cos(\sin(\sin x)) \cos(\sin x) \cos x$$

$$39. y = \sqrt{x + \sqrt{x}} \Rightarrow y' = \frac{1}{2}(x + \sqrt{x})^{-1/2} \left(1 + \frac{1}{2}x^{-1/2}\right) = \frac{1}{2\sqrt{x + \sqrt{x}}} \left(1 + \frac{1}{2\sqrt{x}}\right)$$

$$40. y = \sqrt{x + \sqrt{x + \sqrt{x}}} \Rightarrow y' = \frac{1}{2}(x + \sqrt{x + \sqrt{x}})^{-1/2} \left[1 + \frac{1}{2}(x + \sqrt{x})^{-1/2} \left(1 + \frac{1}{2}x^{-1/2}\right)\right]$$

$$41. y = \sin(\tan \sqrt{\sin x}) \Rightarrow$$

$$y' = \cos(\tan \sqrt{\sin x}) \cdot \frac{d}{dx}(\tan \sqrt{\sin x}) = \cos(\tan \sqrt{\sin x}) \sec^2 \sqrt{\sin x} \cdot \frac{d}{dx}(\sin x)^{1/2}$$

$$= \cos(\tan \sqrt{\sin x}) \sec^2 \sqrt{\sin x} \cdot \frac{1}{2}(\sin x)^{-1/2} \cdot \cos x$$

$$= \cos(\tan \sqrt{\sin x}) \left(\sec^2 \sqrt{\sin x}\right) \left(\frac{1}{2\sqrt{\sin x}}\right) (\cos x)$$

$$42. y = \sqrt{\cos(\sin^2 x)} \Rightarrow y' = \frac{1}{2}(\cos(\sin^2 x))^{-1/2} [-\sin(\sin^2 x)](2 \sin x \cos x) = -\frac{\sin(\sin^2 x) \sin x \cos x}{\sqrt{\cos(\sin^2 x)}}$$

$$43. y = (1 + 2x)^{10} \Rightarrow y' = 10(1 + 2x)^9 \cdot 2 = 20(1 + 2x)^9. \text{ At } (0, 1), y' = 20(1 + 0)^9 = 20, \text{ and an equation of the tangent line is } y - 1 = 20(x - 0), \text{ or } y = 20x + 1.$$

$$44. y = \sin x + \sin^2 x \Rightarrow y' = \cos x + 2 \sin x \cos x. \text{ At } (0, 0), y' = 1, \text{ and an equation of the tangent line is } y - 0 = 1(x - 0), \text{ or } y = x.$$

$$45. y = \sin(\sin x) \Rightarrow y' = \cos(\sin x) \cdot \cos x. \text{ At } (\pi, 0), y' = \cos(\sin \pi) \cdot \cos \pi = \cos(0) \cdot (-1) = 1(-1) = -1, \text{ and an equation of the tangent line is } y - 0 = -1(x - \pi), \text{ or } y = -x + \pi.$$

46. $y = \sqrt{5+x^2} \Rightarrow y' = \frac{1}{2}(5+x^2)^{-1/2}(2x) = x/\sqrt{5+x^2}$. At $(2, 3)$, $y' = \frac{2}{3}$, and an equation of the tangent line is $y - 3 = \frac{2}{3}(x - 2)$, or $y = \frac{2}{3}x + \frac{5}{3}$.

47. (a) $y = f(x) = \tan\left(\frac{\pi}{4}x\right) \Rightarrow f'(x) = \sec^2\left(\frac{\pi}{4}x\right)\left(2 \cdot \frac{\pi}{4}x\right)$.

The slope of the tangent at $(1, 1)$ is thus

$$f'(1) = \sec^2\left(\frac{\pi}{4}\right)\left(\frac{\pi}{2}\right) = 2 \cdot \frac{\pi}{2} = \pi, \text{ and its equation is}$$

$$y - 1 = \pi(x - 1) \text{ or } y = \pi x - \pi + 1.$$

48. (a) For $x > 0$, $|x| = x$, and $y = f(x) = \frac{x}{\sqrt{2-x^2}} \Rightarrow$

$$\begin{aligned} f'(x) &= \frac{\sqrt{2-x^2}(1) - x(\frac{1}{2})(2-x^2)^{-1/2}(-2x)}{(\sqrt{2-x^2})^2} \cdot \frac{(2-x^2)^{1/2}}{(2-x^2)^{1/2}} \\ &= \frac{(2-x^2) + x^2}{(2-x^2)^{3/2}} = \frac{2}{(2-x^2)^{3/2}} \end{aligned}$$

So at $(1, 1)$, the slope of the tangent line is $f'(1) = 2$ and its equation is $y - 1 = 2(x - 1)$ or $y = 2x - 1$.

49. (a) $f(x) = \frac{\sqrt{1-x^2}}{x} \Rightarrow$

$$\begin{aligned} f'(x) &= \frac{x \cdot \frac{1}{2}(1-x^2)^{-1/2}(-2x) - \sqrt{1-x^2}(1)}{x^2} \cdot \frac{\sqrt{1-x^2}}{\sqrt{1-x^2}} \\ &= \frac{-x^2 - (1-x^2)}{x^2 \sqrt{1-x^2}} = \frac{-1}{x^2 \sqrt{1-x^2}} \end{aligned}$$

Notice that all tangents to the graph of f have negative slopes and $f'(x) < 0$ always.

50. (a)

From the graph of f , we see that there are 5 horizontal tangents, so there must be 5 zeros on the graph of f' . From the symmetry of the graph of f , we must have the graph of f' as high at $x = 0$ as it is low at $x = \pi$. The intervals of increase and decrease as well as the signs of f' are indicated in the figure.

$$(b) f(x) = \sin(x + \sin 2x) \Rightarrow$$

$$\begin{aligned} f'(x) &= \cos(x + \sin 2x) \cdot \frac{d}{dx}(x + \sin 2x) \\ &= \cos(x + \sin 2x)(1 + 2 \cos 2x) \end{aligned}$$

51. For the tangent line to be horizontal, $f'(x) = 0$. $f(x) = 2 \sin x + \sin^2 x \Rightarrow$
 $f'(x) = 2 \cos x + 2 \sin x \cos x = 0 \Leftrightarrow 2 \cos x (1 + \sin x) = 0 \Leftrightarrow \cos x = 0$ or $\sin x = -1$, so
 $x = \frac{\pi}{2} + 2n\pi$ or $\frac{3\pi}{2} + 2n\pi$, where n is any integer. Now $f(\frac{\pi}{2}) = 3$ and $f(\frac{3\pi}{2}) = -1$, so the points on the curve
 with a horizontal tangent are $(\frac{\pi}{2} + 2n\pi, 3)$ and $(\frac{3\pi}{2} + 2n\pi, -1)$, where n is any integer.
52. $f(x) = \sin 2x - 2 \sin x \Rightarrow f'(x) = 2 \cos 2x - 2 \cos x = 4 \cos^2 x - 2 \cos x - 2$, and
 $4 \cos^2 x - 2 \cos x - 2 = 0 \Leftrightarrow (\cos x - 1)(4 \cos x + 2) = 0 \Leftrightarrow \cos x = 1$ or $\cos x = -\frac{1}{2}$. So $x = 2n\pi$ or
 $(2n + 1)\pi \pm \frac{\pi}{3}$, n any integer.
53. $F(x) = f(g(x)) \Rightarrow F'(x) = f'(g(x)) \cdot g'(x)$,
 so $F'(3) = f'(g(3)) \cdot g'(3) = f'(6) \cdot g'(3) = 7 \cdot 4 = 28$. Notice that we did not use $f'(3) = 2$.
54. $w = u \circ v \Rightarrow w(x) = u(v(x)) \Rightarrow w'(x) = u'(v(x)) \cdot v'(x)$, so
 $w'(0) = u'(v(0)) \cdot v'(0) = u'(2) \cdot v'(0) = 4 \cdot 5 = 20$. The other pieces of information, $u(0) = 1$, $u'(0) = 3$, and
 $v'(2) = 6$, were not needed.
55. (a) $h(x) = f(g(x)) \Rightarrow h'(x) = f'(g(x)) \cdot g'(x)$, so $h'(1) = f'(g(1)) \cdot g'(1) = f'(2) \cdot 6 = 5 \cdot 6 = 30$.
 (b) $H(x) = g(f(x)) \Rightarrow H'(x) = g'(f(x)) \cdot f'(x)$, so $H'(1) = g'(f(1)) \cdot f'(1) = g'(3) \cdot 4 = 9 \cdot 4 = 36$.
56. (a) $F(x) = f(f(x)) \Rightarrow F'(x) = f'(f(x)) \cdot f'(x)$, so $F'(2) = f'(f(2)) \cdot f'(2) = f'(1) \cdot 5 = 4 \cdot 5 = 20$.
 (b) $G(x) = g(g(x)) \Rightarrow G'(x) = g'(g(x)) \cdot g'(x)$, so $G'(3) = g'(g(3)) \cdot g'(3) = g'(2) \cdot 9 = 7 \cdot 9 = 63$.
57. (a) $u(x) = f(g(x)) \Rightarrow u'(x) = f'(g(x))g'(x)$. So $u'(1) = f'(g(1))g'(1) = f'(3)g'(1)$. To find $f'(3)$, note
 that f is linear from $(2, 4)$ to $(6, 3)$, so its slope is $\frac{3-4}{6-2} = -\frac{1}{4}$. To find $g'(1)$, note that g is linear from $(0, 6)$
 to $(2, 0)$, so its slope is $\frac{0-6}{2-0} = -3$. Thus, $f'(3)g'(1) = (-\frac{1}{4})(-3) = \frac{3}{4}$.
 (b) $v(x) = g(f(x)) \Rightarrow v'(x) = g'(f(x))f'(x)$. So $v'(1) = g'(f(1))f'(1) = g'(2)f'(1)$, which does not exist
 since $g'(2)$ does not exist.
 (c) $w(x) = g(g(x)) \Rightarrow w'(x) = g'(g(x))g'(x)$. So $w'(1) = g'(g(1))g'(1) = g'(3)g'(1)$. To find $g'(3)$, note
 that g is linear from $(2, 0)$ to $(5, 2)$, so its slope is $\frac{2-0}{5-2} = \frac{2}{3}$. Thus, $g'(3)g'(1) = (\frac{2}{3})(-3) = -2$.
58. (a) $h(x) = f(f(x)) \Rightarrow h'(x) = f'(f(x))f'(x)$.
 So $h'(2) = f'(f(2))f'(2) = f'(1)f'(2) \approx (-1)(-1) = 1$.
 (b) $g(x) = f(x^2) \Rightarrow g'(x) = f'(x^2) \cdot \frac{d}{dx}(x^2) = f'(x^2)(2x)$.
 So $g'(2) = f'(2^2)(2 \cdot 2) = 4f'(4) \approx 4(1.5) = 6$.

59. $h(x) = f(g(x)) \Rightarrow h'(x) = f'(g(x))g'(x)$. So $h'(0.5) = f'(g(0.5))g'(0.5) = f'(0.1)g'(0.5)$. We can estimate the derivatives by taking the average of two secant slopes.

$$\text{For } f'(0.1): m_1 = \frac{14.8 - 12.6}{0.1 - 0} = 22, m_2 = \frac{18.4 - 14.8}{0.2 - 0.1} = 36. \text{ So } f'(0.1) \approx \frac{m_1 + m_2}{2} = \frac{22 + 36}{2} = 29.$$

$$\text{For } g'(0.5): m_1 = \frac{0.10 - 0.17}{0.5 - 0.4} = -0.7, m_2 = \frac{0.05 - 0.10}{0.6 - 0.5} = -0.5. \text{ So } g'(0.5) \approx \frac{m_1 + m_2}{2} = -0.6.$$

$$\text{Hence, } h'(0.5) = f'(0.1)g'(0.5) \approx (29)(-0.6) = -17.4.$$

60. $g(x) = f(f(x)) \Rightarrow g'(x) = f'(f(x))f'(x)$. So $g'(1) = f'(f(1))f'(1) = f'(2)f'(1)$.

$$\text{For } f'(2): m_1 = \frac{3.1 - 2.4}{2.0 - 1.5} = 1.4, m_2 = \frac{4.4 - 3.1}{2.5 - 2.0} = 2.6. \text{ So } f'(2) \approx \frac{m_1 + m_2}{2} = 2.$$

$$\text{For } f'(1): m_1 = \frac{2.0 - 1.8}{1.0 - 0.5} = 0.4, m_2 = \frac{2.4 - 2.0}{1.5 - 1.0} = 0.8. \text{ So } f'(1) \approx \frac{m_1 + m_2}{2} = 0.6.$$

$$\text{Hence, } g'(1) = f'(2)f'(1) \approx (2)(0.6) = 1.2.$$

61. (a) $F(x) = f(\cos x) \Rightarrow F'(x) = f'(\cos x) \frac{d}{dx}(\cos x) = -\sin x f'(\cos x)$

$$(b) G(x) = \cos(f(x)) \Rightarrow G'(x) = -\sin(f(x)) f'(x)$$

62. (a) $F(x) = f(x^\alpha) \Rightarrow F'(x) = f'(x^\alpha) \frac{d}{dx}(x^\alpha) = f'(x^\alpha) \alpha x^{\alpha-1}$

$$(b) G(x) = [f(x)]^\alpha \Rightarrow G'(x) = \alpha [f(x)]^{\alpha-1} f'(x)$$

63. (a) $f(x) = L(x^4) \Rightarrow f'(x) = L'(x^4) \cdot 4x^3 = (1/x^4) \cdot 4x^3 = 4/x$ for $x > 0$.

$$(b) g(x) = L(4x) \Rightarrow g'(x) = L'(4x) \cdot 4 = (1/(4x)) \cdot 4 = 1/x$$
 for $x > 0$.

$$(c) F(x) = [L(x)]^4 \Rightarrow F'(x) = 4[L(x)]^3 \cdot L'(x) = 4[L(x)]^3 \cdot (1/x) = 4[L(x)]^3/x$$

$$(d) G(x) = L(1/x) \Rightarrow G'(x) = L'(1/x) \cdot (-1/x^2) = (1/(1/x)) \cdot (-1/x^2) = x \cdot (-1/x^2) = -1/x$$
 for $x > 0$.

64. $r(x) = f(g(h(x))) \Rightarrow r'(x) = f'(g(h(x))) \cdot g'(h(x)) \cdot h'(x)$, so

$$r'(1) = f'(g(h(1))) \cdot g'(h(1)) \cdot h'(1) = f'(g(2)) \cdot g'(2) \cdot 4 = f'(3) \cdot 5 \cdot 4 = 6 \cdot 5 \cdot 4 = 120$$

65. $s(t) = 10 + \frac{1}{4} \sin(10\pi t) \Rightarrow$ the velocity after t seconds is

$$v(t) = s'(t) = \frac{1}{4} \cos(10\pi t)(10\pi) = \frac{5\pi}{2} \cos(10\pi t) \text{ cm/s.}$$

66. (a) $s = A \cos(\omega t + \delta) \Rightarrow$ velocity $= s' = -\omega A \sin(\omega t + \delta)$.

$$(b) \text{ If } A \neq 0 \text{ and } \omega \neq 0, \text{ then } s' = 0 \Leftrightarrow \sin(\omega t + \delta) = 0 \Leftrightarrow \omega t + \delta = n\pi \Leftrightarrow t = \frac{n\pi - \delta}{\omega},$$

n an integer.

67. (a) $B(t) = 4.0 + 0.35 \sin \frac{2\pi t}{5.4} \Rightarrow \frac{dB}{dt} = \left(0.35 \cos \frac{2\pi t}{5.4}\right) \left(\frac{2\pi}{5.4}\right) = \frac{0.7\pi}{5.4} \cos \frac{2\pi t}{5.4} = \frac{7\pi}{54} \cos \frac{2\pi t}{5.4}$

$$(b) \text{ At } t = 1, \frac{dB}{dt} = \frac{7\pi}{54} \cos \frac{2\pi}{5.4} \approx 0.16.$$

68. $L(t) = 12 + 2.8 \sin\left(\frac{2\pi}{365}(t - 80)\right) \Rightarrow L'(t) = 2.8 \cos\left(\frac{2\pi}{365}(t - 80)\right) \left(\frac{2\pi}{365}\right)$.

On March 21, $t = 80$, and $L'(80) \approx 0.0482$ hours per day. On May 21, $t = 141$, and $L'(141) \approx 0.02398$, which is approximately one-half of $L'(80)$.

69. (a) Derive gives $g'(t) = \frac{45(t-2)^8}{(2t+1)^{10}}$ without simplifying. With either Maple or Mathematica, we first get

$$g'(t) = 9 \frac{(t-2)^8}{(2t+1)^9} - 18 \frac{(t-2)^9}{(2t+1)^{10}}, \text{ and the simplification command results in the above expression.}$$

- (b) Derive gives $y' = 2(x^3 - x + 1)^3(2x + 1)^4(17x^3 + 6x^2 - 9x + 3)$ without simplifying.

With either Maple or Mathematica, we first get

$y' = 10(2x + 1)^4(x^3 - x + 1)^4 + 4(2x + 1)^5(x^3 - x + 1)^3(3x^2 - 1)$. If we use Mathematica's Factor or Simplify, or Maple's factor, we get the above expression, but Maple's simplify gives the polynomial expansion instead. For locating horizontal tangents, the factored form is the most helpful.

70. (a) $f(x) = \left(\frac{x^4 - x + 1}{x^4 + x + 1}\right)^{1/2}$. Derive gives $f'(x) = \frac{(3x^4 - 1)\sqrt{\frac{x^4 - x + 1}{x^4 + x + 1}}}{(x^4 + x + 1)(x^4 - x + 1)}$ whereas either Maple or Mathematica give $f'(x) = \frac{3x^4 - 1}{\sqrt{\frac{x^4 - x + 1}{x^4 + x + 1}}(x^4 + x + 1)^2}$ after simplification.

(b) $f'(x) = 0 \Leftrightarrow 3x^4 - 1 = 0 \Leftrightarrow x = \pm\sqrt[4]{\frac{1}{3}} \approx \pm 0.7598$.

- (c) $f'(x) = 0$ where f has horizontal tangents. f' has two maxima and one minimum where f has inflection points.

71. (a) If f is even, then $f(x) = f(-x)$. Using the Chain Rule to differentiate this equation, we get

$$f'(x) = f'(-x) \frac{d}{dx}(-x) = -f'(-x). \text{ Thus, } f'(-x) = -f'(x), \text{ so } f' \text{ is odd.}$$

- (b) If f is odd, then $f(x) = -f(-x)$. Differentiating this equation, we get $f'(x) = -f'(-x)(-1) = f'(-x)$, so f' is even.

72. $\left[\frac{f(x)}{g(x)}\right]' = \{f(x)[g(x)]^{-1}\}' = f'(x)[g(x)]^{-1} + (-1)[g(x)]^{-2}g'(x)f(x)$

$$= \frac{f'(x)}{g(x)} - \frac{f(x)g'(x)}{[g(x)]^2} = \frac{f'(x)g(x) - f(x)g'(x)}{[g(x)]^2}$$

73. (a) $\frac{d}{dx}(\sin^n x \cos nx) = n \sin^{n-1} x \cos x \cos nx + \sin^n x (-n \sin nx)$ [Product Rule]

$$= n \sin^{n-1} x (\cos nx \cos x - \sin nx \sin x)$$
 [factor out $n \sin^{n-1} x$]

$$= n \sin^{n-1} x \cos(nx + x)$$
 [Addition Formula for cosine]

$$= n \sin^{n-1} x \cos[(n+1)x]$$
 [factor out x]

(b) $\frac{d}{dx}(\cos^n x \cos nx) = n \cos^{n-1} x (-\sin x) \cos nx + \cos^n x (-n \sin nx)$ [Product Rule]

$$= -n \cos^{n-1} x (\cos nx \sin x + \sin nx \cos x)$$
 [factor out $-n \cos^{n-1} x$]

$$= -n \cos^{n-1} x \sin(nx + x)$$
 [Addition Formula for sine]

$$= -n \cos^{n-1} x \sin[(n+1)x]$$
 [factor out x]

74. "The rate of change of y^5 with respect to x is eighty times the rate of change of y with respect to x " $\Leftrightarrow$

$$\frac{d}{dx} y^5 = 80 \frac{dy}{dx} \Leftrightarrow 5y^4 \frac{dy}{dx} = 80 \frac{dy}{dx} \Leftrightarrow 5y^4 = 80 \quad (\text{Note that } dy/dx \neq 0 \text{ since the curve never has a horizontal tangent})$$

$$\Leftrightarrow y^4 = 16 \Leftrightarrow y = 2 \quad (\text{since } y > 0 \text{ for all } x)$$

75. Since $\theta^\circ = (\frac{\pi}{180})\theta$ rad, we have $\frac{d}{d\theta}(\sin \theta^\circ) = \frac{d}{d\theta}(\sin \frac{\pi}{180}\theta) = \frac{\pi}{180} \cos \frac{\pi}{180}\theta = \frac{\pi}{180} \cos \theta^\circ$.

76. (a) $f(x) = |x| = \sqrt{x^2} = (x^2)^{1/2} \Rightarrow f'(x) = \frac{1}{2}(x^2)^{-1/2}(2x) = x/\sqrt{x^2} = x/|x|$ for $x \neq 0$.
 f is not differentiable at $x = 0$.

(b) $f(x) = |\sin x| = \sqrt{\sin^2 x} \Rightarrow$

$$f'(x) = \frac{1}{2}(\sin^2 x)^{-1/2} 2 \sin x \cos x = \frac{\sin x}{|\sin x|} \cos x = \begin{cases} \cos x & \text{if } \sin x > 0 \\ -\cos x & \text{if } \sin x < 0 \end{cases}$$

f is not differentiable when $x = n\pi$, n an integer.

(c) $g(x) = \sin |x| = \sin \sqrt{x^2} \Rightarrow g'(x) = \cos |x| \cdot \frac{x}{|x|} = \frac{x}{|x|} \cos x = \begin{cases} \cos x & \text{if } x > 0 \\ -\cos x & \text{if } x < 0 \end{cases}$

g is not differentiable at 0.

77. First note that products and differences of polynomials are polynomials and that the derivative of a polynomial is

also a polynomial. When $n = 1$, $f^{(1)}(x) = \left(\frac{P(x)}{Q(x)}\right)' = \frac{Q(x)P'(x) - P(x)Q'(x)}{[Q(x)]^2} = \frac{A_1(x)}{[Q(x)]^{1+1}}$, where

$A_1(x) = Q(x)P'(x) - P(x)Q'(x)$. Suppose the result is true for $n = k$, where $k \geq 1$. Then

$$f^{(k)}(x) = \frac{A_k(x)}{[Q(x)]^{k+1}}, \text{ so}$$

$$\begin{aligned} f^{(k+1)}(x) &= \left(\frac{A_k(x)}{[Q(x)]^{k+1}}\right)' = \frac{[Q(x)]^{k+1}A'_k(x) - A_k(x) \cdot (k+1)[Q(x)]^k \cdot Q'(x)}{\{[Q(x)]^{k+1}\}^2} \\ &= \frac{[Q(x)]^{k+1}A'_k(x) - (k+1)A_k(x)[Q(x)]^k Q'(x)}{[Q(x)]^{2k+2}} \\ &= \frac{[Q(x)]^k \{[Q(x)]^1 A'_k(x) - (k+1)A_k(x)Q'(x)\}}{[Q(x)]^k [Q(x)]^{k+2}} = \frac{Q(x)A'_k(x) - (k+1)A_k(x)Q'(x)}{[Q(x)]^{k+2}} \\ &= A_{k+1}(x)/[Q(x)]^{k+2}, \text{ where } A_{k+1}(x) = Q(x)A'_k(x) - (k+1)A_k(x)Q'(x). \end{aligned}$$

We have shown that the formula holds for $n = 1$, and that when it holds for $n = k$ it also holds for $n = k + 1$.

Thus, by mathematical induction, the formula holds for all positive integers n .

3.7 Implicit Differentiation

$$1. (a) \frac{d}{dx}(xy + 2x + 3x^2) = \frac{d}{dx}(4) \Rightarrow (x \cdot y' + y \cdot 1) + 2 + 6x = 0 \Rightarrow xy' = -y - 2 - 6x \Rightarrow y' = \frac{-y - 2 - 6x}{x} \text{ or } y' = -6 - \frac{y + 2}{x}.$$

$$(b) xy + 2x + 3x^2 = 4 \Rightarrow xy = 4 - 2x - 3x^2 \Rightarrow y = \frac{4 - 2x - 3x^2}{x} = \frac{4}{x} - 2 - 3x, \text{ so } y' = -\frac{4}{x^2} - 3.$$

$$(c) \text{ From part (a), } y' = \frac{-y - 2 - 6x}{x} = \frac{-(4/x - 2 - 3x) - 2 - 6x}{x} = \frac{-4/x - 3x}{x} = -\frac{4}{x^2} - 3.$$

$$2. (a) \frac{d}{dx}(4x^2 + 9y^2) = \frac{d}{dx}(36) \Rightarrow 8x + 18y \cdot y' = 0 \Rightarrow y' = -\frac{8x}{18y} = -\frac{4x}{9y}$$

$$(b) 4x^2 + 9y^2 = 36 \Rightarrow 9y^2 = 36 - 4x^2 \Rightarrow y^2 = \frac{4}{9}(9 - x^2) \Rightarrow y = \pm \frac{2}{3}\sqrt{9 - x^2}, \text{ so } y' = \pm \frac{2}{3} \cdot \frac{1}{2}(9 - x^2)^{-1/2}(-2x) = \mp \frac{2x}{3\sqrt{9 - x^2}}$$

$$(c) \text{ From part (a), } y' = -\frac{4x}{9y} = -\frac{4x}{9(\pm \frac{2}{3}\sqrt{9 - x^2})} = \mp \frac{2x}{3\sqrt{9 - x^2}}.$$

$$3. (a) \frac{d}{dx}\left(\frac{1}{x} + \frac{1}{y}\right) = \frac{d}{dx}(1) \Rightarrow -\frac{1}{x^2} - \frac{1}{y^2}y' = 0 \Rightarrow -\frac{1}{y^2}y' = \frac{1}{x^2} \Rightarrow y' = -\frac{y^2}{x^2}$$

$$(b) \frac{1}{x} + \frac{1}{y} = 1 \Rightarrow \frac{1}{y} = 1 - \frac{1}{x} = \frac{x-1}{x} \Rightarrow y = \frac{x}{x-1}, \text{ so } y' = \frac{(x-1)(1) - (x)(1)}{(x-1)^2} = \frac{-1}{(x-1)^2}.$$

$$(c) y' = -\frac{y^2}{x^2} = -\frac{[x/(x-1)]^2}{x^2} = -\frac{x^2}{x^2(x-1)^2} = -\frac{1}{(x-1)^2}$$

$$4. (a) \frac{d}{dx}(\sqrt{x} + \sqrt{y}) = \frac{d}{dx}(4) \Rightarrow \frac{1}{2\sqrt{x}} + \frac{1}{2\sqrt{y}}y' = 0 \Rightarrow y' = -\frac{\sqrt{y}}{\sqrt{x}}$$

$$(b) \sqrt{y} = 4 - \sqrt{x} \Rightarrow y = (4 - \sqrt{x})^2 = 16 - 8\sqrt{x} + x \Rightarrow y' = -\frac{4}{\sqrt{x}} + 1$$

$$(c) y' = -\frac{\sqrt{y}}{\sqrt{x}} = -\frac{4 - \sqrt{x}}{\sqrt{x}} = -\frac{4}{\sqrt{x}} + 1$$

$$5. \frac{d}{dx}(x^2 + y^2) = \frac{d}{dx}(1) \Rightarrow 2x + 2yy' = 0 \Rightarrow 2yy' = -2x \Rightarrow y' = -\frac{x}{y}$$

$$6. \frac{d}{dx}(x^2 - y^2) = \frac{d}{dx}(1) \Rightarrow 2x - 2yy' = 0 \Rightarrow 2x = 2yy' \Rightarrow y' = \frac{x}{y}$$

$$7. \frac{d}{dx}(x^3 + x^2y + 4y^2) = \frac{d}{dx}(6) \Rightarrow 3x^2 + (x^2y' + y \cdot 2x) + 8yy' = 0 \Rightarrow x^2y' + 8yy' = -3x^2 - 2xy \Rightarrow (x^2 + 8y)y' = -3x^2 - 2xy \Rightarrow y' = -\frac{3x^2 + 2xy}{x^2 + 8y} = -\frac{x(3x + 2y)}{x^2 + 8y}$$

$$8. \frac{d}{dx}(x^2 - 2xy + y^3) = \frac{d}{dx}(c) \Rightarrow 2x - 2(xy' + y \cdot 1) + 3y^2y' = 0 \Rightarrow 2x - 2y = 2xy' - 3y^2y' \Rightarrow 2x - 2y = y'(2x - 3y^2) \Rightarrow y' = \frac{2x - 2y}{2x - 3y^2}$$

$$9. \frac{d}{dx}(x^2y + xy^2) = \frac{d}{dx}(3x) \Rightarrow (x^2y' + y \cdot 2x) + (x \cdot 2yy' + y^2 \cdot 1) = 3 \Rightarrow$$

$$x^2y' + 2xyy' = 3 - 2xy - y^2 \Rightarrow y'(x^2 + 2xy) = 3 - 2xy - y^2 \Rightarrow y' = \frac{3 - 2xy - y^2}{x^2 + 2xy}$$

$$10. \frac{d}{dx}(y^5 + x^2y^3) = \frac{d}{dx}(1 + x^4y) \Rightarrow 5y^4y' + x^2 \cdot 3y^2y' + y^3 \cdot 2x = 0 + x^4y' + y \cdot 4x^3 \Rightarrow$$

$$y'(5y^4 + 3x^2y^2 - x^4) = 4x^3y - 2xy^3 \Rightarrow y' = \frac{4x^3y - 2xy^3}{5y^4 + 3x^2y^2 - x^4}$$

$$11. \frac{d}{dx}(x^2y^2 + x \sin y) = \frac{d}{dx}(4) \Rightarrow x^2 \cdot 2yy' + y^2 \cdot 2x + x \cos y \cdot y' + \sin y \cdot 1 = 0 \Rightarrow$$

$$2x^2yy' + x \cos y \cdot y' = -2xy^2 - \sin y \Rightarrow (2x^2y + x \cos y)y' = -2xy^2 - \sin y \Rightarrow y' = \frac{-2xy^2 - \sin y}{2x^2y + x \cos y}$$

$$12. \frac{d}{dx}(1 + x) = \frac{d}{dx}[\sin(xy^2)] \Rightarrow 1 = [\cos(xy^2)](x \cdot 2yy' + y^2 \cdot 1) \Rightarrow 1 = 2xy \cos(xy^2)y' + y^2 \cos(xy^2)$$

$$\Rightarrow 1 - y^2 \cos(xy^2) = 2xy \cos(xy^2)y' \Rightarrow y' = \frac{1 - y^2 \cos(xy^2)}{2xy \cos(xy^2)}$$

$$13. \frac{d}{dx}(4 \cos x \sin y) = \frac{d}{dx}(1) \Rightarrow 4[\cos x \cdot \cos y \cdot y' + \sin y \cdot (-\sin x)] = 0 \Rightarrow$$

$$y'(4 \cos x \cos y) = 4 \sin x \sin y \Rightarrow y' = \frac{4 \sin x \sin y}{4 \cos x \cos y} = \tan x \tan y$$

$$14. \frac{d}{dx}[y \sin(x^2)] = \frac{d}{dx}[x \sin(y^2)] \Rightarrow y \cos(x^2) \cdot 2x + \sin(x^2) \cdot y' = x \cos(y^2) \cdot 2yy' + \sin(y^2) \cdot 1 \Rightarrow$$

$$y'[\sin(x^2) - 2xy \cos(y^2)] = \sin(y^2) - 2xy \cos(x^2) \Rightarrow y' = \frac{\sin(y^2) - 2xy \cos(x^2)}{\sin(x^2) - 2xy \cos(y^2)}$$

$$15. \frac{d}{dx}[\tan(x/y)] = \frac{d}{dx}(x + y) \Rightarrow \sec^2(x/y) \cdot \frac{y \cdot 1 - x \cdot y'}{y^2} = 1 + y' \Rightarrow$$

$$y \sec^2(x/y) - x \sec^2(x/y) \cdot y' = y^2 + y^2 y' \Rightarrow y \sec^2(x/y) - y^2 = y^2 y' + x \sec^2(x/y) \Rightarrow$$

$$y \sec^2(x/y) - y^2 = [y^2 + x \sec^2(x/y)] \cdot y' \Rightarrow y' = \frac{y \sec^2(x/y) - y^2}{y^2 + x \sec^2(x/y)}$$

$$16. \frac{d}{dx}(\sqrt{x+y}) = \frac{d}{dx}(1 + x^2y^2) \Rightarrow \frac{1}{2}(x+y)^{-1/2}(1+y') = x^2 \cdot 2yy' + y^2 \cdot 2x \Rightarrow$$

$$\frac{1}{2\sqrt{x+y}} + \frac{y'}{2\sqrt{x+y}} = 2x^2yy' + 2xy^2 \Rightarrow 1 + y' = 4x^2y\sqrt{x+y}y' + 4xy^2\sqrt{x+y} \Rightarrow$$

$$y' - 4x^2y\sqrt{x+y}y' = 4xy^2\sqrt{x+y} - 1 \Rightarrow y'(1 - 4x^2y\sqrt{x+y}) = 4xy^2\sqrt{x+y} - 1 \Rightarrow$$

$$y' = \frac{4xy^2\sqrt{x+y} - 1}{1 - 4x^2y\sqrt{x+y}}$$

$$17. \sqrt{xy} = 1 + x^2y \Rightarrow \frac{1}{2}(xy)^{-1/2}(xy' + y \cdot 1) = 0 + x^2y' + y \cdot 2x \Rightarrow \frac{x}{2\sqrt{xy}}y' + \frac{y}{2\sqrt{xy}} = x^2y' + 2xy$$

$$\Rightarrow y'\left(\frac{x}{2\sqrt{xy}} - x^2\right) = 2xy - \frac{y}{2\sqrt{xy}} \Rightarrow y'\left(\frac{x - 2x^2\sqrt{xy}}{2\sqrt{xy}}\right) = \frac{4xy\sqrt{xy} - y}{2\sqrt{xy}} \Rightarrow y' = \frac{4xy\sqrt{xy} - y}{x - 2x^2\sqrt{xy}}$$

18. $\tan(x - y) = \frac{y}{1 + x^2} \Rightarrow (1 + x^2) \tan(x - y) = y \Rightarrow$
 $(1 + x^2) \sec^2(x - y) \cdot (1 - y') + \tan(x - y) \cdot 2x = y' \Rightarrow$
 $(1 + x^2) \sec^2(x - y) - (1 + x^2) \sec^2(x - y) \cdot y' + 2x \tan(x - y) = y' \Rightarrow$
 $(1 + x^2) \sec^2(x - y) + 2x \tan(x - y) = [1 + (1 + x^2) \sec^2(x - y)] \cdot y' \Rightarrow$
 $y' = \frac{(1 + x^2) \sec^2(x - y) + 2x \tan(x - y)}{1 + (1 + x^2) \sec^2(x - y)}$
19. $xy = \cot(xy) \Rightarrow y + xy' = -\csc^2(xy)(y + xy') \Rightarrow (y + xy')[1 + \csc^2(xy)] = 0 \Rightarrow$
 $y + xy' = 0$ [since $1 + \csc^2(xy) > 0$] $\Rightarrow y' = -y/x$
20. $\sin x + \cos y = \sin x \cos y \Rightarrow \cos x - \sin y \cdot y' = \sin x (-\sin y \cdot y') + \cos y \cos x \Rightarrow$
 $(\sin x \sin y - \sin y) y' = \cos x \cos y - \cos x \Rightarrow y' = \frac{\cos x (\cos y - 1)}{\sin y (\sin x - 1)}$
21. $\frac{d}{dx} \{1 + f(x) + x^2[f(x)]^3\} = \frac{d}{dx}(0) \Rightarrow f'(x) + x^2 \cdot 3[f(x)]^2 \cdot f'(x) + [f(x)]^3 \cdot 2x = 0$. If $x = 1$, we have
 $f'(1) + 1^2 \cdot 3[f(1)]^2 \cdot f'(1) + [f(1)]^3 \cdot 2(1) = 0 \Rightarrow f'(1) + 1 \cdot 3 \cdot 2^2 \cdot f'(1) + 2^3 \cdot 2 = 0 \Rightarrow$
 $f'(1) + 12f'(1) = -16 \Rightarrow 13f'(1) = -16 \Rightarrow f'(1) = -\frac{16}{13}$.
22. $\frac{d}{dx} [g(x) + x \sin g(x)] = \frac{d}{dx}(x^2) \Rightarrow g'(x) + x \cos g(x) \cdot g'(x) + \sin g(x) \cdot 1 = 2x$. If $x = 1$, we have
 $g'(1) + 1 \cos g(1) \cdot g'(1) + \sin g(1) = 2(1) \Rightarrow g'(1) + \cos 0 \cdot g'(1) + \sin 0 = 2 \Rightarrow g'(1) + g'(1) = 2 \Rightarrow$
 $2g'(1) = 2 \Rightarrow g'(1) = 1$.
23. $y^4 + x^2 y^2 + yx^4 = y + 1 \Rightarrow 4y^3 + \left(x^2 \cdot 2y + y^2 \cdot 2x \frac{dx}{dy}\right) + \left(y \cdot 4x^3 \frac{dx}{dy} + x^4 \cdot 1\right) = 1 \Rightarrow$
 $2xy^2 \frac{dx}{dy} + 4x^3 y \frac{dx}{dy} = 1 - 4y^3 - 2x^2 y - x^4 \Rightarrow \frac{dx}{dy} = \frac{1 - 4y^3 - 2x^2 y - x^4}{2xy^2 + 4x^3 y}$
24. $(x^2 + y^2)^2 = ax^2 y \Rightarrow 2(x^2 + y^2) \left(2x \frac{dx}{dy} + 2y\right) = 2axy \frac{dx}{dy} + ax^2 \Rightarrow \frac{dx}{dy} = \frac{ax^2 - 4y(x^2 + y^2)}{4x(x^2 + y^2) - 2axy}$
25. $x^2 + xy + y^2 = 3 \Rightarrow 2x + xy' + y \cdot 1 + 2yy' = 0 \Rightarrow xy' + 2yy' = -2x - y \Rightarrow$
 $y'(x + 2y) = -2x - y \Rightarrow y' = \frac{-2x - y}{x + 2y}$. When $x = 1$ and $y = 1$, we have $y' = \frac{-2 - 1}{1 + 2 \cdot 1} = \frac{-3}{3} = -1$, so
an equation of the tangent line is $y - 1 = -1(x - 1)$ or $y = -x + 2$.
26. $x^2 + 2xy - y^2 + x = 2 \Rightarrow 2x + 2(xy' + y \cdot 1) - 2yy' + 1 = 0 \Rightarrow 2xy' - 2yy' = -2x - 2y - 1 \Rightarrow$
 $y'(2x - 2y) = -2x - 2y - 1 \Rightarrow y' = \frac{-2x - 2y - 1}{2x - 2y}$. When $x = 1$ and $y = 2$, we have
 $y' = \frac{-2 - 4 - 1}{2 - 4} = \frac{-7}{-2} = \frac{7}{2}$, so an equation of the tangent line is $y - 2 = \frac{7}{2}(x - 1)$ or $y = \frac{7}{2}x - \frac{3}{2}$.

27. $x^2 + y^2 = (2x^2 + 2y^2 - x)^2 \Rightarrow 2x + 2yy' = 2(2x^2 + 2y^2 - x)(4x + 4yy' - 1)$. When $x = 0$ and $y = \frac{1}{2}$, we have $0 + y' = 2(\frac{1}{2})(2y' - 1) \Rightarrow y' = 2y' - 1 \Rightarrow y' = 1$, so an equation of the tangent line is $y - \frac{1}{2} = 1(x - 0)$ or $y = x + \frac{1}{2}$.

28. $x^{2/3} + y^{2/3} = 4 \Rightarrow \frac{2}{3}x^{-1/3} + \frac{2}{3}y^{-1/3}y' = 0 \Rightarrow \frac{1}{\sqrt[3]{x}} + \frac{y'}{\sqrt[3]{y}} = 0 \Rightarrow y' = -\frac{\sqrt[3]{y}}{\sqrt[3]{x}}$. When $x = -3\sqrt{3}$ and $y = 1$, we have $y' = -\frac{1}{(-3\sqrt{3})^{1/3}} = -\frac{(-3\sqrt{3})^{2/3}}{-3\sqrt{3}} = \frac{3}{3\sqrt{3}} = \frac{1}{\sqrt{3}}$, so an equation of the tangent line is $y - 1 = \frac{1}{\sqrt{3}}(x + 3\sqrt{3})$ or $y = \frac{1}{\sqrt{3}}x + 4$.

29. $2(x^2 + y^2)^2 = 25(x^2 - y^2) \Rightarrow 4(x^2 + y^2)(2x + 2yy') = 25(2x - 2yy') \Rightarrow 4(x + yy')(x^2 + y^2) = 25(x - yy') \Rightarrow 4yy'(x^2 + y^2) + 25yy' = 25x - 4x(x^2 + y^2) \Rightarrow y' = \frac{25x - 4x(x^2 + y^2)}{25y + 4y(x^2 + y^2)}$. When $x = 3$ and $y = 1$, we have $y' = \frac{75 - 120}{25 + 40} = -\frac{45}{65} = -\frac{9}{13}$, so an equation of the tangent line is $y - 1 = -\frac{9}{13}(x - 3)$ or $y = -\frac{9}{13}x + \frac{40}{13}$.

30. $y^2(y^2 - 4) = x^2(x^2 - 5) \Rightarrow y^4 - 4y^2 = x^4 - 5x^2 \Rightarrow 4y^3y' - 8yy' = 4x^3 - 10x$. When $x = 0$ and $y = -2$, we have $-32y' + 16y' = 0 \Rightarrow -16y' = 0 \Rightarrow y' = 0$, so an equation of the tangent line is $y + 2 = 0(x - 0)$ or $y = -2$.

31. (a) $y^2 = 5x^4 - x^2 \Rightarrow 2yy' = 5(4x^3) - 2x \Rightarrow y' = \frac{10x^3 - x}{y}$. (b)

So at the point $(1, 2)$ we have $y' = \frac{10(1)^3 - 1}{2} = \frac{9}{2}$, and an

equation of the tangent line is $y - 2 = \frac{9}{2}(x - 1)$ or $y = \frac{9}{2}x - \frac{5}{2}$.

32. (a) $y^2 = x^3 + 3x^2 \Rightarrow 2yy' = 3x^2 + 3(2x) \Rightarrow y' = \frac{3x^2 + 6x}{2y}$. So at the point $(1, -2)$ we have

$y' = \frac{3(1)^2 + 6(1)}{2(-2)} = -\frac{9}{4}$, and an equation of the tangent line is $y + 2 = -\frac{9}{4}(x - 1)$ or $y = -\frac{9}{4}x + \frac{1}{4}$.

(b) The curve has a horizontal tangent where $y' = 0 \Leftrightarrow$

$$3x^2 + 6x = 0 \Leftrightarrow 3x(x + 2) = 0 \Leftrightarrow x = 0 \text{ or } x = -2. \text{ But}$$

note that at $x = 0, y = 0$ also, so the derivative does not exist. At

$x = -2, y^2 = (-2)^3 + 3(-2)^2 = -8 + 12 = 4$, so $y = \pm 2$. So the

two points at which the curve has a horizontal tangent are $(-2, -2)$

and $(-2, 2)$.

(c)

33. (a)

There are eight points with horizontal tangents:
four at $x \approx 1.57735$ and four at $x \approx 0.42265$.

(d) By multiplying the right side of the equation by $x - 3$, we obtain the first graph.

By modifying the equation in other ways, we can generate the other graphs.

$$(b) y' = \frac{3x^2 - 6x + 2}{2(2y^3 - 3y^2 - y + 1)} \Rightarrow y' = -1 \text{ at}$$

$$(0, 1) \text{ and } y' = \frac{1}{3} \text{ at } (0, 2).$$

Equations of the tangent lines are $y = -x + 1$
and $y = \frac{1}{3}x + 2$.

$$(c) y' = 0 \Rightarrow 3x^2 - 6x + 2 = 0 \Rightarrow x = 1 \pm \frac{1}{3}\sqrt{3}$$

$$\begin{aligned} y(y^2 - 1)(y - 2) \\ = x(x - 1)(x - 2)(x - 3) \end{aligned}$$

$$\begin{aligned} y(y^2 - 4)(y - 2) \\ = x(x - 1)(x - 2) \end{aligned}$$

$$\begin{aligned} y(y + 1)(y^2 - 1)(y - 2) \\ = x(x - 1)(x - 2) \end{aligned}$$

$$\begin{aligned} (y + 1)(y^2 - 1)(y - 2) \\ = (x - 1)(x - 2) \end{aligned}$$

$$\begin{aligned} x(y + 1)(y^2 - 1)(y - 2) \\ = y(x - 1)(x - 2) \end{aligned}$$

$$\begin{aligned} y(y^2 + 1)(y - 2) \\ = x(x^2 - 1)(x - 2) \end{aligned}$$

$$\begin{aligned} y(y + 1)(y^2 - 2) \\ = x(x - 1)(x^2 - 2) \end{aligned}$$

41. $2x^2 + y^2 = 3$ and $x = y^2$ intersect when $2x^2 + x - 3 = 0 \Leftrightarrow (2x + 3)(x - 1) = 0 \Leftrightarrow x = -\frac{3}{2}$ or 1, but $-\frac{3}{2}$ is extraneous since $x = y^2$ is nonnegative. When $x = 1$, $1 = y^2 \Rightarrow y = \pm 1$, so there are two points of intersection: $(1, \pm 1)$. $2x^2 + y^2 = 3 \Rightarrow 4x + 2yy' = 0 \Rightarrow y' = -2x/y$, and $x = y^2 \Rightarrow 1 = 2yy' \Rightarrow y' = 1/(2y)$. At $(1, 1)$, the slopes are $m_1 = -2(1)/1 = -2$ and $m_2 = 1/(2 \cdot 1) = \frac{1}{2}$, so the curves are orthogonal (since m_1 and m_2 are negative reciprocals of each other). By symmetry, the curves are also orthogonal at $(1, -1)$.
42. $x^2 - y^2 = 5$ and $4x^2 + 9y^2 = 72$ intersect when $4x^2 + 9(x^2 - 5) = 72 \Leftrightarrow 13x^2 = 117 \Leftrightarrow x = \pm 3$, so there are four points of intersection: $(\pm 3, \pm 2)$. $x^2 - y^2 = 5 \Rightarrow 2x - 2yy' = 0 \Rightarrow y' = x/y$, and $4x^2 + 9y^2 = 72 \Rightarrow 8x + 18yy' = 0 \Leftrightarrow y' = -4x/9y$. At $(3, 2)$, the slopes are $m_1 = \frac{3}{2}$ and $m_2 = -\frac{2}{3}$, so the curves are orthogonal. By symmetry, the curves are also orthogonal at $(3, -2)$, $(-3, 2)$ and $(-3, -2)$.

44. The orthogonal family represents the direction of the wind.

45. $x^2 + y^2 = r^2$ is a circle with center O and $ax + by = 0$ is a line through O .
 $x^2 + y^2 = r^2 \Rightarrow 2x + 2yy' = 0 \Rightarrow y' = -x/y$, so the slope of the tangent line at $P_0(x_0, y_0)$ is $-x_0/y_0$. The slope of the line OP_0 is y_0/x_0 , which is the negative reciprocal of $-x_0/y_0$. Hence, the curves are orthogonal, and the families of curves are orthogonal trajectories of each other.

46. The circles $x^2 + y^2 = ax$ and $x^2 + y^2 = by$ intersect at the origin where the tangents are vertical and horizontal. If (x_0, y_0) is the other point of intersection, then $x_0^2 + y_0^2 = ax_0$ (1) and $x_0^2 + y_0^2 = by_0$ (2). Now $x^2 + y^2 = ax \Rightarrow 2x + 2yy' = a \Rightarrow y' = \frac{a - 2x}{2y}$ and $x^2 + y^2 = by \Rightarrow 2x + 2yy' = by' \Rightarrow y' = \frac{2x}{b - 2y}$. Thus, the curves are orthogonal at $(x_0, y_0) \Leftrightarrow \frac{a - 2x_0}{2y_0} = -\frac{b - 2y_0}{2x_0} \Leftrightarrow 2ax_0 - 4x_0^2 = 4y_0^2 - 2by_0 \Leftrightarrow ax_0 + by_0 = 2(x_0^2 + y_0^2)$, which is true by (1) and (2).

47. $y = cx^2 \Rightarrow y' = 2cx$ and $x^2 + 2y^2 = k \Rightarrow 2x + 4yy' = 0 \Rightarrow$
 $2yy' = -x \Rightarrow y' = -\frac{x}{2(y)} = -\frac{x}{2(cx^2)} = -\frac{1}{2cx}$, so the curves are
 orthogonal.

48. $y = ax^3 \Rightarrow y' = 3ax^2$ and $x^2 + 3y^2 = b \Rightarrow 2x + 6yy' = 0 \Rightarrow$
 $3yy' = -x \Rightarrow y' = -\frac{x}{3(y)} = -\frac{x}{3(ax^3)} = -\frac{1}{3ax^2}$, so the curves are
 orthogonal.

49. To find the points at which the ellipse $x^2 - xy + y^2 = 3$ crosses the x -axis, let $y = 0$ and solve for x .

$y = 0 \Rightarrow x^2 - x(0) + 0^2 = 3 \Leftrightarrow x = \pm\sqrt{3}$. So the graph of the ellipse crosses the x -axis at the points $(\pm\sqrt{3}, 0)$. Using implicit differentiation to find y' , we get $2x - xy' - y + 2yy' = 0 \Rightarrow y'(2y - x) = y - 2x$
 $\Leftrightarrow y' = \frac{y - 2x}{2y - x}$. So y' at $(\sqrt{3}, 0)$ is $\frac{0 - 2\sqrt{3}}{2(0) - \sqrt{3}} = 2$ and y' at $(-\sqrt{3}, 0)$ is $\frac{0 + 2\sqrt{3}}{2(0) + \sqrt{3}} = 2$. Thus, the tangent
 lines at these points are parallel.

50. (a) We use implicit differentiation to find $y' = \frac{y - 2x}{2y - x}$ as in Exercise 49.

The slope of the tangent line at $(-1, 1)$ is $m = \frac{1 - 2(-1)}{2(1) - (-1)} = \frac{3}{3} = 1$,

so the slope of the normal line is $-\frac{1}{m} = -1$, and its equation is

$y - 1 = -1(x + 1) \Leftrightarrow y = -x$. Substituting $-x$ for y in the

equation of the ellipse, we get $x^2 - x(-x) + (-x)^2 = 3 \Rightarrow$

$3x^2 = 3 \Leftrightarrow x = \pm 1$. So the normal line must intersect the ellipse
 again at $x = 1$, and since the equation of the line is $y = -x$, the other
 point of intersection must be $(1, -1)$.

(b)

51. $x^2y^2 + xy = 2 \Rightarrow x^2 \cdot 2yy' + y^2 \cdot 2x + x \cdot y' + y \cdot 1 = 0 \Leftrightarrow y'(2x^2y + x) = -2xy^2 - y \Leftrightarrow$
 $y' = -\frac{2xy^2 + y}{2x^2y + x}$. So $-\frac{2xy^2 + y}{2x^2y + x} = -1 \Leftrightarrow 2xy^2 + y = 2x^2y + x \Leftrightarrow y(2xy + 1) = x(2xy + 1) \Leftrightarrow$
 $y(2xy + 1) - x(2xy + 1) = 0 \Leftrightarrow (2xy + 1)(y - x) = 0 \Leftrightarrow xy = -\frac{1}{2}$ or $y = x$. But $xy = -\frac{1}{2} \Rightarrow$
 $x^2y^2 + xy = \frac{1}{4} - \frac{1}{2} \neq 2$, so we must have $x = y$. Then $x^2y^2 + xy = 2 \Rightarrow x^4 + x^2 = 2 \Leftrightarrow$
 $x^4 + x^2 - 2 = 0 \Leftrightarrow (x^2 + 2)(x^2 - 1) = 0$. So $x^2 = -2$, which is impossible, or $x^2 = 1 \Leftrightarrow x = \pm 1$.
 Since $x = y$, the points on the curve where the tangent line has a slope of -1 are $(-1, -1)$ and $(1, 1)$.

52. $x^2 + 4y^2 = 36 \Rightarrow 2x + 8yy' = 0 \Rightarrow y' = -\frac{x}{4y}$. Let (a, b) be a point on $x^2 + 4y^2 = 36$ whose tangent line passes through $(12, 3)$. The tangent line is then $y - 3 = -\frac{a}{4b}(x - 12)$, so $b - 3 = -\frac{a}{4b}(a - 12)$. Multiplying both sides by $4b$ gives $4b^2 - 12b = -a^2 + 12a$, so $4b^2 + a^2 = 12(a + b)$. But $4b^2 + a^2 = 36$, so $36 = 12(a + b) \Rightarrow a + b = 3 \Rightarrow b = 3 - a$. Substituting $3 - a$ for b into $a^2 + 4b^2 = 36$ gives $a^2 + 4(3 - a)^2 = 36 \Leftrightarrow a^2 + 36 - 24a + 4a^2 = 36 \Leftrightarrow 5a^2 - 24a = 0 \Leftrightarrow a(5a - 24) = 0$, so $a = 0$ or $a = \frac{24}{5}$. If $a = 0$, $b = 3 - 0 = 3$, and if $a = \frac{24}{5}$, $b = 3 - \frac{24}{5} = -\frac{9}{5}$. So the two points on the ellipse are $(0, 3)$ and $(\frac{24}{5}, -\frac{9}{5})$. Using $y - 3 = -\frac{a}{4b}(x - 12)$ with $(a, b) = (0, 3)$ gives us the tangent line $y - 3 = 0$ or $y = 3$. With $(a, b) = (\frac{24}{5}, -\frac{9}{5})$, we have $y - 3 = -\frac{24/5}{4(-9/5)}(x - 12) \Leftrightarrow y - 3 = \frac{2}{3}(x - 12) \Leftrightarrow y = \frac{2}{3}x - 5$. A graph of the ellipse and the tangent lines confirms our results.

53. $x^2 + 4y^2 = 5 \Rightarrow 2x + 4(2yy') = 0 \Rightarrow y' = -\frac{x}{4y}$. Now let h be the height of the lamp, and let (a, b) be the point of tangency of the line passing through the points $(3, h)$ and $(-5, 0)$. This line has slope $(h - 0)/(3 - (-5)) = \frac{1}{8}h$. But the slope of the tangent line through the point (a, b) can be expressed as $y' = -\frac{a}{4b}$, or as $\frac{b - 0}{a - (-5)} = \frac{b}{a + 5}$ [since the line passes through $(-5, 0)$ and (a, b)], so $-\frac{a}{4b} = \frac{b}{a + 5} \Leftrightarrow 4b^2 = -a^2 - 5a \Leftrightarrow a^2 + 4b^2 = -5a$. But $a^2 + 4b^2 = 5$ [since (a, b) is on the ellipse], so $5 = -5a \Leftrightarrow a = -1$. Then $4b^2 = -a^2 - 5a = -1 - 5(-1) = 4 \Rightarrow b = 1$, since the point is on the top half of the ellipse. So $\frac{h}{8} = \frac{b}{a + 5} = \frac{1}{-1 + 5} = \frac{1}{4} \Rightarrow h = 2$. So the lamp is located 2 units above the x -axis.

3.8 Higher Derivatives

1. $a = f$, $b = f'$, $c = f''$. We can see this because where a has a horizontal tangent, $b = 0$, and where b has a horizontal tangent, $c = 0$. We can immediately see that c can be neither f nor f' , since at the points where c has a horizontal tangent, neither a nor b is equal to 0.
2. Where d has horizontal tangents, only c is 0, so $d' = c$. c has negative tangents for $x < 0$ and b is the only graph that is negative for $x < 0$, so $c' = b$. b has positive tangents on $\mathbb{R}$ (except at $x = 0$), and the only graph that is positive on the same domain is a , so $b' = a$. We conclude that $d = f$, $c = f'$, $b = f''$, and $a = f'''$.
3. We can immediately see that a is the graph of the acceleration function, since at the points where a has a horizontal tangent, neither c nor b is equal to 0. Next, we note that $a = 0$ at the point where b has a horizontal tangent, so b must be the graph of the velocity function, and hence, $b' = a$. We conclude that c is the graph of the position function.
4. a must be the jerk since none of the graphs are 0 at its high and low points. a is 0 where b has a maximum, so $b' = a$. b is 0 where c has a maximum, so $c' = b$. We conclude that d is the position function, c is the velocity, b is the acceleration, and a is the jerk.

5. $f(x) = x^5 + 6x^2 - 7x \Rightarrow f'(x) = 5x^4 + 12x - 7 \Rightarrow f''(x) = 20x^3 + 12$
6. $f(t) = t^8 - 7t^6 + 2t^4 \Rightarrow f'(t) = 8t^7 - 42t^5 + 8t^3 \Rightarrow f''(t) = 56t^6 - 210t^4 + 24t^2$
7. $y = \cos 2\theta \Rightarrow y' = -2 \sin 2\theta \Rightarrow y'' = -4 \cos 2\theta$
8. $y = \theta \sin \theta \Rightarrow y' = \theta \cos \theta + \sin \theta \Rightarrow y'' = \theta(-\sin \theta) + \cos \theta \cdot 1 + \cos \theta = 2 \cos \theta - \theta \sin \theta$
9. $F(t) = (1 - 7t)^6 \Rightarrow F'(t) = 6(1 - 7t)^5(-7) = -42(1 - 7t)^5 \Rightarrow$
 $F''(t) = -42 \cdot 5(1 - 7t)^4(-7) = 1470(1 - 7t)^4$
10. $g(x) = \frac{2x+1}{x-1} \Rightarrow g'(x) = \frac{(x-1)(2) - (2x+1)(1)}{(x-1)^2} = \frac{2x-2-2x-1}{(x-1)^2} = \frac{-3}{(x-1)^2} \text{ or } -3(x-1)^{-2}$
 $\Rightarrow g''(x) = -3(-2)(x-1)^{-3} = 6(x-1)^{-3} \text{ or } \frac{6}{(x-1)^3}$
11. $h(u) = \frac{1-4u}{1+3u} \Rightarrow h'(u) = \frac{(1+3u)(-4) - (1-4u)(3)}{(1+3u)^2} = \frac{-4-12u-3+12u}{(1+3u)^2} = \frac{-7}{(1+3u)^2} \text{ or}$
 $-7(1+3u)^{-2} \Rightarrow h''(u) = -7(-2)(1+3u)^{-3}(3) = 42(1+3u)^{-3} \text{ or } \frac{42}{(1+3u)^3}$

36. $f(x) = \sqrt{x} = x^{1/2} \Rightarrow f'(x) = \frac{1}{2}x^{-1/2} \Rightarrow$
 $f''(x) = \frac{1}{2}\left(-\frac{1}{2}\right)x^{-3/2} \Rightarrow f'''(x) = \frac{1}{2}\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)x^{-5/2} \Rightarrow$
 $f^{(4)}(x) = \frac{1}{2}\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)\left(-\frac{5}{2}\right)x^{-7/2} = -\frac{1 \cdot 3 \cdot 5}{2^4}x^{-7/2} \Rightarrow$
 $f^{(5)}(x) = \frac{1}{2}\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)\left(-\frac{5}{2}\right)\left(-\frac{7}{2}\right)x^{-9/2} = \frac{1 \cdot 3 \cdot 5 \cdot 7}{2^5}x^{-9/2} \Rightarrow \dots \Rightarrow$
 $f^{(n)}(x) = \frac{1}{2}\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right) \dots \left(\frac{1}{2} - n + 1\right)x^{-(2n-1)/2} = (-1)^{n-1} \frac{1 \cdot 3 \cdot 5 \cdot \dots \cdot (2n-3)}{2^n} x^{-(2n-1)/2}$
37. $f(x) = 1/(3x^3) = \frac{1}{3}x^{-3} \Rightarrow f'(x) = \frac{1}{3}(-3)x^{-4} \Rightarrow f''(x) = \frac{1}{3}(-3)(-4)x^{-5} \Rightarrow$
 $f'''(x) = \frac{1}{3}(-3)(-4)(-5)x^{-6} \Rightarrow \dots \Rightarrow$
 $f^{(n)}(x) = \frac{1}{3}(-3)(-4) \dots [-(n+2)]x^{-(n+3)} = \frac{(-1)^n \cdot 3 \cdot 4 \cdot 5 \cdot \dots \cdot (n+2)}{3x^{n+3}} \cdot \frac{2}{2} = \frac{(-1)^n (n+2)!}{6x^{n+3}}$
38. $D \sin x = \cos x \Rightarrow D^2 \sin x = -\sin x \Rightarrow D^3 \sin x = -\cos x \Rightarrow D^4 \sin x = \sin x$. The derivatives of $\sin x$ occur in a cycle of four. Since $74 = 4(18) + 2$, we have $D^{74} \sin x = D^2 \sin x = -\sin x$.
39. Let $f(x) = \cos x$. Then $Df(2x) = 2f'(2x)$, $D^2 f(2x) = 2^2 f''(2x)$, $D^3 f(2x) = 2^3 f'''(2x)$, $\dots$,
 $D^{(n)} f(2x) = 2^n f^{(n)}(2x)$. Since the derivatives of $\cos x$ occur in a cycle of four, and since $103 = 4(25) + 3$, we have $f^{(103)}(x) = f^{(3)}(x) = \sin x$ and $D^{103} \cos 2x = 2^{103} f^{(103)}(2x) = 2^{103} \sin 2x$.
40. Let $f(x) = x \sin x$ and $h(x) = \sin x$, so $f(x) = xh(x)$. Then
 $f'(x) = h(x) + xh'(x)$, $f''(x) = h'(x) + h'(x) + xh''(x) = 2h'(x) + xh''(x)$,
 $f'''(x) = 2h''(x) + h''(x) + xh'''(x) = 3h''(x) + xh'''(x)$, $\dots$, $f^{(n)}(x) = nh^{(n-1)}(x) + xh^{(n)}(x)$. Since
 $34 = 4(8) + 2$, we have $h^{(34)}(x) = h^{(2)}(x) = D^2 \sin x = -\sin x$ and $h^{(35)}(x) = -\cos x$. Thus,
 $D^{(35)} x \sin x = 35h^{(34)}(x) + xh^{(35)}(x) = -35 \sin x - x \cos x$.
41. By measuring the slope of the graph of $s = f(t)$ at $t = 0, 1, 2, 3, 4$, and 5 , and using the method of Example 1 in Section 3.2, we plot the graph of the velocity function $v = f'(t)$ in the first figure. The acceleration when $t = 2$ s is $a = f''(2)$, the slope of the tangent line to the graph of f' when $t = 2$. We estimate the slope of this tangent line to be $a(2) = f''(2) = v'(2) \approx \frac{27}{3} = 9 \text{ ft/s}^2$. Similar measurements enable us to graph the acceleration function in the second figure.

42. (a) Since we estimate the velocity to be a maximum at $t = 10$, the acceleration is 0 at $t = 10$.

(b) Drawing a tangent line at $t = 10$ on the graph of a , a appears to decrease by 10 ft/s^2 over a period of 20 s. So at $t = 10$ s, the jerk is approximately $-10/20 = -0.5 \text{ (ft/s}^2\text{)/s}$ or ft/s^3 .

43. (a) $s = 2t^3 - 15t^2 + 36t + 2 \Rightarrow v(t) = s'(t) = 6t^2 - 30t + 36 \Rightarrow a(t) = v'(t) = 12t - 30$

(b) $a(1) = 12 \cdot 1 - 30 = -18 \text{ m/s}^2$

(c) $v(t) = 6(t^2 - 5t + 6) = 6(t - 2)(t - 3) = 0$ when $t = 2$ or 3 and $a(2) = 24 - 30 = -6 \text{ m/s}^2$,
 $a(3) = 36 - 30 = 6 \text{ m/s}^2$.

44. (a) $s = 2t^3 - 3t^2 - 12t \Rightarrow v(t) = s'(t) = 6t^2 - 6t - 12 \Rightarrow a(t) = v'(t) = 12t - 6$

(b) $a(1) = 12 \cdot 1 - 6 = 6 \text{ m/s}^2$

(c) $v(t) = 6(t^2 - t - 2) = 6(t + 1)(t - 2) = 0$ when $t = -1$ or 2. Since $t \geq 0$, $t \neq -1$ and
 $a(2) = 24 - 6 = 18 \text{ m/s}^2$.

45. (a) $s = \sin(\frac{\pi}{6}t) + \cos(\frac{\pi}{6}t)$, $0 \leq t \leq 2$. $v(t) = s'(t) = \cos(\frac{\pi}{6}t) \cdot \frac{\pi}{6} - \sin(\frac{\pi}{6}t) \cdot \frac{\pi}{6} = \frac{\pi}{6} [\cos(\frac{\pi}{6}t) - \sin(\frac{\pi}{6}t)]$
 $\Rightarrow a(t) = v'(t) = \frac{\pi}{6} [-\sin(\frac{\pi}{6}t) \cdot \frac{\pi}{6} - \cos(\frac{\pi}{6}t) \cdot \frac{\pi}{6}] = -\frac{\pi^2}{36} [\sin(\frac{\pi}{6}t) + \cos(\frac{\pi}{6}t)]$

(b) $a(1) = -\frac{\pi^2}{36} [\sin(\frac{\pi}{6} \cdot 1) + \cos(\frac{\pi}{6} \cdot 1)] = -\frac{\pi^2}{36} [\frac{1}{2} + \frac{\sqrt{3}}{2}] = -\frac{\pi^2}{72} (1 + \sqrt{3}) \approx -0.3745 \text{ m/s}^2$

(c) $v(t) = 0$ for $0 \leq t \leq 2 \Rightarrow \cos(\frac{\pi}{6}t) = \sin(\frac{\pi}{6}t) \Rightarrow 1 = \frac{\sin(\frac{\pi}{6}t)}{\cos(\frac{\pi}{6}t)} \Rightarrow$

$\tan(\frac{\pi}{6}t) = 1 \Rightarrow \frac{\pi}{6}t = \tan^{-1} 1 \Rightarrow t = \frac{6}{\pi} \cdot \frac{\pi}{4} = \frac{3}{2} = 1.5 \text{ s. Thus,}$

$a(\frac{3}{2}) = -\frac{\pi^2}{36} [\sin(\frac{\pi}{6} \cdot \frac{3}{2}) + \cos(\frac{\pi}{6} \cdot \frac{3}{2})] = -\frac{\pi^2}{36} [\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}] = -\frac{\pi^2}{36} \sqrt{2} \approx -0.3877 \text{ m/s}^2$.

46. (a) $s = 2t^3 - 7t^2 + 4t + 1 \Rightarrow v(t) = s'(t) = 6t^2 - 14t + 4 \Rightarrow a(t) = v'(t) = 12t - 14$

(b) $a(1) = 12 - 14 = -2 \text{ m/s}^2$

(c) $v(t) = 2(3t^2 - 7t + 2) = 2(3t - 1)(t - 2) = 0$ when $t = \frac{1}{3}$ or 2 and $a(\frac{1}{3}) = 12(\frac{1}{3}) - 14 = -10 \text{ m/s}^2$,
 $a(2) = 12(2) - 14 = 10 \text{ m/s}^2$.

47. (a) $s(t) = t^4 - 4t^3 + 2 \Rightarrow v(t) = s'(t) = 4t^3 - 12t^2 \Rightarrow a(t) = v'(t) = 12t^2 - 24t = 12t(t - 2) = 0$
when $t = 0$ or 2.

(b) $s(0) = 2 \text{ m}$, $v(0) = 0 \text{ m/s}$, $s(2) = -14 \text{ m}$, $v(2) = -16 \text{ m/s}$

48. (a) $s(t) = 2t^3 - 9t^2 \Rightarrow v(t) = s'(t) = 6t^2 - 18t \Rightarrow a(t) = v'(t) = 12t - 18 = 0$ when $t = 1.5$.

(b) $s(1.5) = -13.5 \text{ m}$, $v(1.5) = -13.5 \text{ m/s}$

49. (a) $s = f(t) = t^3 - 12t^2 + 36t$, $t \geq 0 \Rightarrow v(t) = f'(t) = 3t^2 - 24t + 36$.

$a(t) = v'(t) = 6t - 24$. $a(3) = 6(3) - 24 = -6 \text{ (m/s)/s}$ or m/s^2 .

(c) The particle is speeding up when v and a have the same sign. This occurs when $2 < t < 4$ and when $t > 6$. It is slowing down when v and a have opposite signs; that is, when $0 \leq t < 2$ and when $4 < t < 6$.

$$50. (a) x(t) = \frac{t}{1+t^2} \Rightarrow v(t) = x'(t) = \frac{(1+t^2)(1) - t(2t)}{(1+t^2)^2} = \frac{1-t^2}{(1+t^2)^2}.$$

$$a(t) = v'(t) = \frac{2t(t^2-3)}{(1+t^2)^3}. a(t) = 0 \Rightarrow 2t(t^2-3) = 0 \Rightarrow t = 0 \text{ or } \sqrt{3}$$

(c) v and a have the same sign and the particle is speeding up when $1 < t < \sqrt{3}$. The particle is slowing down and v and a have opposite signs when $0 < t < 1$ and when $t > \sqrt{3}$.

$$51. (a) y(t) = A \sin \omega t \Rightarrow v(t) = y'(t) = A\omega \cos \omega t \Rightarrow a(t) = v'(t) = -A\omega^2 \sin \omega t$$

$$(b) a(t) = -A\omega^2 \sin \omega t = -\omega^2(A \sin \omega t) = -\omega^2 y(t), \text{ so } a(t) \text{ is proportional to } y(t).$$

(c) speed $= |v(t)| = A\omega |\cos \omega t|$ is a maximum when $\cos \omega t = \pm 1$. But when $\cos \omega t = \pm 1$, we have $\sin \omega t = 0$, and $a(t) = -A\omega^2 \sin \omega t = -A\omega^2(0) = 0$.

52. By the Chain Rule, $a(t) = \frac{dv}{dt} = \frac{dv}{ds} \frac{ds}{dt} = \frac{dv}{ds} v(t) = v(t) \frac{dv}{ds}$. The derivative dv/dt is the rate of change of the velocity with respect to time (in other words, the acceleration) whereas the derivative dv/ds is the rate of change of the velocity with respect to the displacement.

$$53. \text{ Let } P(x) = ax^2 + bx + c. \text{ Then } P'(x) = 2ax + b \text{ and } P''(x) = 2a. P''(2) = 2 \Rightarrow 2a = 2 \Rightarrow a = 1. \\ P'(2) = 3 \Rightarrow 2(1)(2) + b = 3 \Rightarrow 4 + b = 3 \Rightarrow b = -1.$$

$$P(2) = 5 \Rightarrow 1(2)^2 + (-1)(2) + c = 5 \Rightarrow 2 + c = 5 \Rightarrow c = 3. \text{ So } P(x) = x^2 - x + 3.$$

$$54. \text{ Let } Q(x) = ax^3 + bx^2 + cx + d. \text{ Then } Q'(x) = 3ax^2 + 2bx + c, Q''(x) = 6ax + 2b \text{ and } Q'''(x) = 6a. \text{ Thus,} \\ Q(1) = a + b + c + d = 1, Q'(1) = 3a + 2b + c = 3, Q''(1) = 6a + 2b = 6 \text{ and } Q'''(1) = 6a = 12. \text{ Solving} \\ \text{these four equations in four unknowns } a, b, c \text{ and } d \text{ we get } a = 2, b = -3, c = 3 \text{ and } d = -1, \text{ so} \\ Q(x) = 2x^3 - 3x^2 + 3x - 1.$$

$$55. y = A \sin x + B \cos x \Rightarrow y' = A \cos x - B \sin x \Rightarrow y'' = -A \sin x - B \cos x. \text{ Substituting into} \\ y'' + y' - 2y = \sin x \text{ gives us } (-3A - B) \sin x + (A - 3B) \cos x = 1 \sin x, \text{ so we must have } -3A - B = 1 \\ \text{and } A - 3B = 0. \text{ Solving for } A \text{ and } B, \text{ we add the first equation to three times the second to get } B = -\frac{1}{10} \\ \text{and } A = -\frac{3}{10}.$$

$$56. y = Ax^2 + Bx + C \Rightarrow y' = 2Ax + B \Rightarrow y'' = 2A. \text{ We substitute these expressions into the equation} \\ y'' + y' - 2y = x^2 \text{ to get}$$

$$(2A) + (2Ax + B) - 2(Ax^2 + Bx + C) = x^2$$

$$2A + 2Ax + B - 2Ax^2 - 2Bx - 2C = x^2$$

$$(-2A)x^2 + (2A - 2B)x + (2A + B - 2C) = (1)x^2 + (0)x + (0)$$

The coefficients of x^2 on each side must be equal, so $-2A = 1 \Rightarrow A = -\frac{1}{2}$. Similarly, $2A - 2B = 0 \Rightarrow A = B = -\frac{1}{2}$ and $2A + B - 2C = 0 \Rightarrow -1 - \frac{1}{2} - 2C = 0 \Rightarrow C = -\frac{3}{4}$.

$$57. f(x) = xg(x^2) \Rightarrow f'(x) = x \cdot g'(x^2) \cdot 2x + g(x^2) \cdot 1 = g(x^2) + 2x^2 g'(x^2) \Rightarrow \\ f''(x) = g'(x^2) \cdot 2x + 2x^2 \cdot g''(x^2) \cdot 2x + g'(x^2) \cdot 4x = 6xg'(x^2) + 4x^3 g''(x^2)$$

$$58. f(x) = \frac{g(x)}{x} \Rightarrow f'(x) = \frac{xg'(x) - g(x)}{x^2} \Rightarrow$$

$$f''(x) = \frac{x^2[g'(x) + xg''(x) - g'(x)] - 2x[xg'(x) - g(x)]}{x^4} = \frac{x^2g''(x) - 2xg'(x) + 2g(x)}{x^3}$$

$$59. f(x) = g(\sqrt{x}) \Rightarrow f'(x) = g'(\sqrt{x}) \cdot \frac{1}{2}x^{-1/2} = \frac{g'(\sqrt{x})}{2\sqrt{x}} \Rightarrow$$

$$f''(x) = \frac{2\sqrt{x} \cdot g''(\sqrt{x}) \cdot \frac{1}{2}x^{-1/2} - g'(\sqrt{x}) \cdot 2 \cdot \frac{1}{2}x^{-1/2}}{(2\sqrt{x})^2} = \frac{x^{-1/2}[\sqrt{x}g''(\sqrt{x}) - g'(\sqrt{x})]}{4x}$$

$$= \frac{\sqrt{x}g''(\sqrt{x}) - g'(\sqrt{x})}{4x\sqrt{x}}$$

60.

$$f(x) = 3x^5 - 10x^3 + 5 \Rightarrow f'(x) = 15x^4 - 30x^2 \Rightarrow$$

$$f''(x) = 60x^3 - 60x = 60x(x^2 - 1) = 60x(x+1)(x-1)$$

So $f''(x) > 0$ when $-1 < x < 0$ or $x > 1$, and on these intervals the graph of f lies above its tangent lines; and $f''(x) < 0$ when $x < -1$ or $0 < x < 1$, and on these intervals the graph of f lies below its tangent lines.

$$61. (a) f(x) = \frac{1}{x^2 + x} \Rightarrow f'(x) = \frac{-(2x+1)}{(x^2+x)^2} \Rightarrow$$

$$f''(x) = \frac{(x^2+x)^2(-2) + (2x+1)(2)(x^2+x)(2x+1)}{(x^2+x)^4} = \frac{2(3x^2+3x+1)}{(x^2+x)^3} \Rightarrow$$

$$f'''(x) = \frac{(x^2+x)^3(2)(6x+3) - 2(3x^2+3x+1)(3)(x^2+x)^2(2x+1)}{(x^2+x)^6}$$

$$= \frac{-6(4x^3+6x^2+4x+1)}{(x^2+x)^4} \Rightarrow$$

$$f^{(4)}(x) = \frac{(x^2+x)^4(-6)(12x^2+12x+4) + 6(4x^3+6x^2+4x+1)(4)(x^2+x)^3(2x+1)}{(x^2+x)^8}$$

$$= \frac{24(5x^4+10x^3+10x^2+5x+1)}{(x^2+x)^5}$$

$$f^{(5)}(x) = ?$$

$$(b) f(x) = \frac{1}{x(x+1)} = \frac{1}{x} - \frac{1}{x+1} \Rightarrow f'(x) = -x^{-2} + (x+1)^{-2} \Rightarrow f''(x) = 2x^{-3} - 2(x+1)^{-3} \Rightarrow$$

$$f'''(x) = (-3)(2)x^{-4} + (3)(2)(x+1)^{-4} \Rightarrow \dots \Rightarrow f^{(n)}(x) = (-1)^n n! [x^{-(n+1)} - (x+1)^{-(n+1)}]$$

$$62. (a) \text{ For } f(x) = \frac{7x+17}{2x^2-7x-4}, \text{ a CAS gives us } f'''(x) = \frac{-6(56x^4+544x^3-2184x^2+6184x-6139)}{(2x^2-7x-4)^4}$$

$$(b) \text{ Using a CAS we get } f(x) = \frac{7x+17}{2x^2-7x-4} = \frac{-3}{2x+1} + \frac{5}{x-4}. \text{ Now we differentiate three times to obtain}$$

$$f'''(x) = \frac{144}{(2x+1)^4} - \frac{30}{(x-4)^4}.$$

63. We will show that for each positive integer n , the n th derivative $f^{(n)}$ exists and equals one of $f, f', f'', f''', \dots, f^{(p-1)}$. Since $f^{(p)} = f$, the first p derivatives of f are $f', f'', f''', \dots, f^{(p-1)}$, and f . In particular, our statement is true for $n = 1$. Suppose that k is an integer, $k \geq 1$, for which f is k -times differentiable with $f^{(k)}$ in the set

$S = \{f, f', f'', \dots, f^{(p-1)}\}$. Since f is p -times differentiable, every member of S [including $f^{(k)}$] is differentiable, so $f^{(k+1)}$ exists and equals the derivative of some member of S . Thus, $f^{(k+1)}$ is in the set $\{f', f'', f''', \dots, f^{(p)}\}$, which equals S since $f^{(p)} = f$. We have shown that the statement is true for $n = 1$ and that its truth for $n = k$ implies its truth for $n = k + 1$. By mathematical induction, the statement is true for all positive integers n .

64. (a) Use the Product Rule repeatedly: $F = fg \Rightarrow F' = f'g + fg' \Rightarrow$

$$F'' = (f''g + f'g') + (f'g' + fg'') = f''g + 2f'g' + fg''.$$

- (b) $F''' = f'''g + f''g' + 2(f''g' + f'g'') + f'g'' + fg''' = f'''g + 3f''g' + 3f'g'' + fg''' \Rightarrow$

$$\begin{aligned} F^{(4)} &= f^{(4)}g + f'''g' + 3(f'''g' + f''g'') + 3(f''g'' + f'g''') + f'g''' + fg^{(4)} \\ &= f^{(4)}g + 4f'''g' + 6f''g'' + 4f'g''' + fg^{(4)} \end{aligned}$$

- (c) By analogy with the Binomial Theorem, we make the guess:

$$F^{(n)} = f^{(n)}g + n f^{(n-1)}g' + \binom{n}{2} f^{(n-2)}g'' + \dots + \binom{n}{k} f^{(n-k)}g^{(k)} + \dots + n f'g^{(n-1)} + fg^{(n)}$$

$$\text{where } \binom{n}{k} = \frac{n!}{k!(n-k)!} = \frac{n(n-1)(n-2)\cdots(n-k+1)}{k!}.$$

65. The Chain Rule says that $\frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx}$, so

$$\begin{aligned} \frac{d^2y}{dx^2} &= \frac{d}{dx} \left(\frac{dy}{dx} \right) = \frac{d}{dx} \left(\frac{dy}{du} \frac{du}{dx} \right) = \left[\frac{d}{dx} \left(\frac{dy}{du} \right) \right] \frac{du}{dx} + \frac{dy}{du} \frac{d}{dx} \left(\frac{du}{dx} \right) \quad [\text{Product Rule}] \\ &= \left[\frac{d}{du} \left(\frac{dy}{du} \right) \frac{du}{dx} \right] \frac{du}{dx} + \frac{dy}{du} \frac{d^2u}{dx^2} = \frac{d^2y}{du^2} \left(\frac{du}{dx} \right)^2 + \frac{dy}{du} \frac{d^2u}{dx^2} \end{aligned}$$

66. From Exercise 65, $\frac{d^2y}{dx^2} = \frac{d^2y}{du^2} \left(\frac{du}{dx} \right)^2 + \frac{dy}{du} \frac{d^2u}{dx^2} \Rightarrow$

$$\begin{aligned} \frac{d^3y}{dx^3} &= \frac{d}{dx} \frac{d^2y}{dx^2} = \frac{d}{dx} \left[\frac{d^2y}{du^2} \left(\frac{du}{dx} \right)^2 \right] + \frac{d}{dx} \left[\frac{dy}{du} \frac{d^2u}{dx^2} \right] \\ &= \left[\frac{d}{dx} \left(\frac{d^2y}{du^2} \right) \right] \left(\frac{du}{dx} \right)^2 + \left[\frac{d}{dx} \left(\frac{du}{dx} \right)^2 \right] \frac{d^2y}{du^2} + \left[\frac{d}{dx} \left(\frac{dy}{du} \right) \right] \frac{d^2u}{dx^2} + \left[\frac{d}{dx} \left(\frac{d^2u}{dx^2} \right) \right] \frac{dy}{du} \\ &= \left[\frac{d}{du} \left(\frac{d^2y}{du^2} \right) \frac{du}{dx} \right] \left(\frac{du}{dx} \right)^2 + 2 \frac{du}{dx} \frac{d^2u}{dx^2} \frac{d^2y}{du^2} + \left[\frac{d}{du} \left(\frac{dy}{du} \right) \frac{du}{dx} \right] \left(\frac{d^2u}{dx^2} \right) + \frac{d^3u}{dx^3} \frac{dy}{du} \\ &= \frac{d^3y}{du^3} \left(\frac{du}{dx} \right)^3 + 3 \frac{du}{dx} \frac{d^2u}{dx^2} \frac{d^2y}{du^2} + \frac{dy}{du} \frac{d^3u}{dx^3} \end{aligned}$$

APPLIED PROJECT Where Should a Pilot Start Descent?

1. Condition (i) will hold if and only if all of the following four conditions hold:

$$(\alpha) P(0) = 0$$

$$(\beta) P'(0) = 0 \text{ (for a smooth landing)}$$

(γ) $P'(\ell) = 0$ (since the plane is cruising horizontally when it begins its descent)

(δ) $P(\ell) = h$.

First of all, condition α implies that $P(0) = d = 0$, so $P(x) = ax^3 + bx^2 + cx \Rightarrow P'(x) = 3ax^2 + 2bx + c$.

But $P'(0) = c = 0$ by condition β . So $P'(\ell) = 3a\ell^2 + 2b\ell = \ell(3a\ell + 2b)$. Now by condition γ ,

$3a\ell + 2b = 0 \Rightarrow a = -\frac{2b}{3\ell}$. Therefore, $P(x) = -\frac{2b}{3\ell}x^3 + bx^2$. Setting $P(\ell) = h$ for condition δ , we get

$P(\ell) = -\frac{2b}{3\ell}\ell^3 + b\ell^2 = h \Rightarrow -\frac{2}{3}b\ell^2 + b\ell^2 = h \Rightarrow \frac{1}{3}b\ell^2 = h \Rightarrow b = \frac{3h}{\ell^2} \Rightarrow a = -\frac{2h}{\ell^3}$. So

$$y = P(x) = -\frac{2h}{\ell^3}x^3 + \frac{3h}{\ell^2}x^2.$$

2. By condition (ii), $\frac{dx}{dt} = -v$ for all t , so $x(t) = \ell - vt$. Condition (iii) states that $\left| \frac{d^2y}{dt^2} \right| \leq k$. By the Chain Rule,

we have $\frac{dy}{dt} = \frac{dy}{dx} \frac{dx}{dt} = -\frac{2h}{\ell^3}(3x^2) \frac{dx}{dt} + \frac{3h}{\ell^2}(2x) \frac{dx}{dt} = \frac{6hx^2v}{\ell^3} - \frac{6h xv}{\ell^2}$ (for $x \leq \ell$) $\Rightarrow$

$\frac{d^2y}{dt^2} = \frac{6hv}{\ell^3}(2x) \frac{dx}{dt} - \frac{6hv}{\ell^2} \frac{dx}{dt} = -\frac{12hv^2}{\ell^3}x + \frac{6hv^2}{\ell^2}$. In particular, when $t = 0$, $x = \ell$ and so

$\left. \frac{d^2y}{dt^2} \right|_{t=0} = -\frac{12hv^2}{\ell^3}\ell + \frac{6hv^2}{\ell^2} = -\frac{6hv^2}{\ell^2}$. Thus, $\left| \frac{d^2y}{dt^2} \right|_{t=0} = \frac{6hv^2}{\ell^2} \leq k$. (This condition also follows from taking $x = 0$.)

3. We substitute $k = 860 \text{ mi/h}^2$, $h = 35,000 \text{ ft} \times \frac{1 \text{ mi}}{5280 \text{ ft}}$, and $v = 300 \text{ mi/h}$ into the result of part (b):

$$\frac{6(35,000 \cdot \frac{1}{5280})(300)^2}{\ell^2} \leq 860 \Rightarrow \ell \geq 300 \sqrt{6 \cdot \frac{35,000}{5280 \cdot 860}} \approx 64.5 \text{ miles}.$$

4. Substituting the values of h and ℓ in Problem 3 into $P(x) = -\frac{2h}{\ell^3}x^3 + \frac{3h}{\ell^2}x^2$ gives us $P(x) = ax^3 + bx^2$, where $a \approx 4.937 \times 10^{-5}$ and $b \approx 4.78 \times 10^{-3}$.

APPLIED PROJECT Building a Better Roller Coaster

1. (a) $f(x) = ax^2 + bx + c \Rightarrow f'(x) = 2ax + b$.

The origin is at P : $f(0) = 0 \Rightarrow c = 0$

The slope of the ascent is 0.8: $f'(0) = 0.8 \Rightarrow b = 0.8$

The slope of the drop is -1.6: $f'(100) = -1.6 \Rightarrow 200a + b = -1.6$

(b) $b = 0.8$, so $200a + b = -1.6 \Rightarrow 200a + 0.8 = -1.6 \Rightarrow 200a = -2.4 \Rightarrow a = -\frac{2.4}{200} = -0.012$.

Thus, $f(x) = -0.012x^2 + 0.8x$.

- (c) Since L_1 passes through the origin with slope 0.8, it has equation $y = 0.8x$. The horizontal distance between P and Q is 100, so the y -coordinate at Q is $f(100) = -0.012(100)^2 + 0.8(100) = -40$. Since L_2 passes through the point $(100, -40)$ and has slope -1.6 , it has equation $y + 40 = -1.6(x - 100)$ or $y = -1.6x + 120$.

- (d) The difference in elevation between $P(0, 0)$ and $Q(100, -40)$ is $0 - (-40) = 40$ feet.

2. (a)

Interval	Function	First Derivative	Second Derivative
$(-\infty, 0)$	$L_1(x) = 0.8x$	$L'_1(x) = 0.8$	$L''_1(x) = 0$
$[0, 10]$	$g(x) = kx^3 + lx^2 + mx + n$	$g'(x) = 3kx^2 + 2lx + m$	$g''(x) = 6kx + 2l$
$[10, 90]$	$q(x) = ax^2 + bx + c$	$q'(x) = 2ax + b$	$q''(x) = 2a$
$(90, 100]$	$h(x) = px^3 + qx^2 + rx + s$	$h'(x) = 3px^2 + 2qx + r$	$h''(x) = 6px + 2q$
$(100, \infty)$	$L_2(x) = -1.6x + 120$	$L'_2(x) = -1.6$	$L''_2(x) = 0$

There are 4 values of x (0, 10, 90, and 100) for which we must make sure the function values are equal, the first derivative values are equal, and the second derivative values are equal. The third column in the following table contains the value of each side of the condition—these are found after solving the system in part (b).

At $x =$	Condition	Value	Resulting Equation
0	$g(0) = L_1(0)$	0	$n = 0$
	$g'(0) = L'_1(0)$	$\frac{4}{5}$	$m = 0.8$
	$g''(0) = L''_1(0)$	0	$2l = 0$
10	$g(10) = q(10)$	$\frac{68}{9}$	$1000k + 100l + 10m + n = 100a + 10b + c$
	$g'(10) = q'(10)$	$\frac{2}{3}$	$300k + 20l + m = 20a + b$
	$g''(10) = q''(10)$	$-\frac{2}{75}$	$60k + 2l = 2a$
90	$h(90) = q(90)$	$-\frac{220}{9}$	$729,000p + 8100q + 90r + s = 8100a + 90b + c$
	$h'(90) = q'(90)$	$-\frac{22}{15}$	$24,300p + 180q + r = 180a + b$
	$h''(90) = q''(90)$	$-\frac{2}{75}$	$540p + 2q = 2a$
100	$h(100) = L_2(100)$	-40	$1,000,000p + 10,000q + 100r + s = -40$
	$h'(100) = L'_2(100)$	$-\frac{8}{5}$	$30,000p + 200q + r = -1.6$
	$h''(100) = L''_2(100)$	0	$600p + 2q = 0$

(b) We can arrange our work in a 12×12 matrix as follows.

a	b	c	k	l	m	n	p	q	r	s	constant
0	0	0	0	0	0	1	0	0	0	0	0
0	0	0	0	0	1	0	0	0	0	0	0.8
0	0	0	0	2	0	0	0	0	0	0	0
-100	-10	-1	1000	100	10	1	0	0	0	0	0
-20	-1	0	300	20	1	0	0	0	0	0	0
-2	0	0	60	2	0	0	0	0	0	0	0
-8100	-90	-1	0	0	0	0	729,000	8100	90	1	0
-180	-1	0	0	0	0	0	24,300	180	1	0	0
-2	0	0	0	0	0	0	540	2	0	0	0
0	0	0	0	0	0	0	1,000,000	10,000	100	1	-40
0	0	0	0	0	0	0	30,000	200	1	0	-1.6
0	0	0	0	0	0	0	600	2	0	0	0

Solving the system gives us the formulas for q , g , and h .

$$\left. \begin{aligned} a &= -0.01\bar{3} = -\frac{1}{75} \\ b &= 0.9\bar{3} = \frac{14}{15} \\ c &= -0.4 = -\frac{4}{9} \end{aligned} \right\} q(x) = -\frac{1}{75}x^2 + \frac{14}{15}x - \frac{4}{9}$$

$$\left. \begin{aligned} k &= -0.000\bar{4} = -\frac{1}{2250} \\ l &= 0 \\ m &= 0.8 = \frac{4}{5} \\ n &= 0 \end{aligned} \right\} g(x) = -\frac{1}{2250}x^3 + \frac{4}{5}x$$

$$\left. \begin{aligned} p &= 0.000\bar{4} = \frac{1}{2250} \\ q &= -0.1\bar{3} = -\frac{2}{15} \\ r &= 11.7\bar{3} = \frac{176}{15} \\ s &= -324.\bar{4} = -\frac{2920}{9} \end{aligned} \right\} h(x) = \frac{1}{2250}x^3 - \frac{2}{15}x^2 + \frac{176}{15}x - \frac{2920}{9}$$

(c) Graph of L_1 , q , g , h , and L_2 :

The graph of the five functions as a piecewise-defined function:

This is the piecewise-defined function assignment on a TI-83 Plus calculator, where $Y_2 = L_1$, $Y_6 = g$, $Y_5 = q$, $Y_7 = h$, and $Y_3 = L_2$.

3.9 Related Rates

$$1. V = x^3 \Rightarrow \frac{dV}{dt} = \frac{dV}{dx} \frac{dx}{dt} = 3x^2 \frac{dx}{dt}$$

$$2. (a) A = \pi r^2 \Rightarrow \frac{dA}{dt} = \frac{dA}{dr} \frac{dr}{dt} = 2\pi r \frac{dr}{dt} \quad (b) \frac{dA}{dt} = 2\pi r \frac{dr}{dt} = 2\pi(30 \text{ m})(1 \text{ m/s}) = 60\pi \text{ m}^2/\text{s}$$

$$3. y = x^3 + 2x \Rightarrow \frac{dy}{dt} = \frac{dy}{dx} \frac{dx}{dt} = (3x^2 + 2)(5) = 5(3x^2 + 2). \text{ When } x = 2, \frac{dy}{dt} = 5(14) = 70.$$

$$4. x^2 + y^2 = 25 \Rightarrow 2x \frac{dx}{dt} + 2y \frac{dy}{dt} = 0 \Rightarrow x \frac{dx}{dt} = -y \frac{dy}{dt} \Rightarrow \frac{dx}{dt} = -\frac{y}{x} \frac{dy}{dt}$$

$$\text{When } y = 4, x^2 + 4^2 = 25 \Rightarrow x = \pm 3. \text{ For } \frac{dy}{dt} = 6, \frac{dx}{dt} = -\frac{4}{\pm 3}(6) = \mp 8.$$

$$5. z^2 = x^2 + y^2 \Rightarrow 2z \frac{dz}{dt} = 2x \frac{dx}{dt} + 2y \frac{dy}{dt} \Rightarrow \frac{dz}{dt} = \frac{1}{z} \left(x \frac{dx}{dt} + y \frac{dy}{dt} \right). \text{ When } x = 5 \text{ and } y = 12,$$

$$z^2 = 5^2 + 12^2 \Rightarrow z^2 = 169 \Rightarrow z = \pm 13. \text{ For } \frac{dx}{dt} = 2 \text{ and } \frac{dy}{dt} = 3, \frac{dz}{dt} = \frac{1}{\pm 13} (5 \cdot 2 + 12 \cdot 3) = \pm \frac{46}{13}.$$

$$6. y = \sqrt{1+x^3} \Rightarrow \frac{dy}{dt} = \frac{dy}{dx} \frac{dx}{dt} = \frac{1}{2}(1+x^3)^{-1/2} (3x^2) \frac{dx}{dt} = \frac{3x^2}{2\sqrt{1+x^3}} \frac{dx}{dt}. \text{ With } \frac{dy}{dt} = 4 \text{ when } x = 2 \text{ and}$$

$$y = 3, \text{ we have } 4 = \frac{3(4)}{2(3)} \frac{dx}{dt} \Rightarrow \frac{dx}{dt} = 2 \text{ cm/s.}$$

7. (a) Given: a plane flying horizontally at an altitude of 1 mi and a speed of 500 mi/h passes directly over a radar station. If we let t be time (in hours) and x be the horizontal distance traveled by the plane (in mi), then we are given that $dx/dt = 500$ mi/h.

- (b) Unknown: the rate at which the distance from the plane to the station is increasing when it is 2 mi from the station. If we let y be the distance from the plane to the station, then we want to find dy/dt when $y = 2$ mi.

- (d) By the Pythagorean Theorem, $y^2 = x^2 + 1 \Rightarrow 2y(dy/dt) = 2x(dx/dt)$.

- (e) $\frac{dy}{dt} = \frac{x}{y} \frac{dx}{dt} = \frac{x}{y} (500)$. Since $y^2 = x^2 + 1$, when $y = 2$, $x = \sqrt{3}$, so $\frac{dy}{dt} = \frac{\sqrt{3}}{2} (500) = 250\sqrt{3} \approx 433$ mi/h.

8. (a) Given: the rate of decrease of the surface area is 1 cm²/min. If we let t be time (in minutes) and S be the surface area (in cm²), then we are given that $dS/dt = -1$ cm²/s.

- (b) Unknown: the rate of decrease of the diameter when the diameter is 10 cm. If we let x be the diameter, then we want to find dx/dt when $x = 10$ cm.

- (d) If the radius is r and the diameter $x = 2r$, then $r = \frac{1}{2}x$ and $S = 4\pi r^2 = 4\pi(\frac{1}{2}x)^2 = \pi x^2 \Rightarrow$

$$\frac{dS}{dt} = \frac{dS}{dx} \frac{dx}{dt} = 2\pi x \frac{dx}{dt}.$$

- (e) $-1 = \frac{dS}{dt} = 2\pi x \frac{dx}{dt} \Rightarrow \frac{dx}{dt} = -\frac{1}{2\pi x}$. When $x = 10$, $\frac{dx}{dt} = -\frac{1}{20\pi}$. So the rate of decrease is $\frac{1}{20\pi}$ cm/min.

9. (a) Given: a man 6 ft tall walks away from a street light mounted on a 15-ft-tall pole at a rate of 5 ft/s. If we let t be time (in s) and x be the distance from the pole to the man (in ft), then we are given that $dx/dt = 5$ ft/s.

- (b) Unknown: the rate at which the tip of his shadow is moving when he is 40 ft from the pole. If we let y be the distance from the man to the tip of his shadow (in ft), then we want to find $\frac{d}{dt}(x + y)$ when $x = 40$ ft.

- (d) By similar triangles, $\frac{15}{6} = \frac{x+y}{y} \Rightarrow 15y = 6x + 6y \Rightarrow 9y = 6x \Rightarrow y = \frac{2}{3}x$.

- (e) The tip of the shadow moves at a rate of $\frac{d}{dt}(x + y) = \frac{d}{dt}(x + \frac{2}{3}x) = \frac{5}{3} \frac{dx}{dt} = \frac{5}{3}(5) = \frac{25}{3}$ ft/s.

10. (a) Given: at noon, ship A is 150 km west of ship B; ship A is sailing east at 35 km/h, and ship B is sailing north at 25 km/h. If we let t be time (in hours), x be the distance traveled by ship A (in km), and y be the distance traveled by ship B (in km), then we are given that $dx/dt = 35$ km/h and $dy/dt = 25$ km/h.

- (b) Unknown: the rate at which the distance between the ships is changing at 4:00 P.M. If we let z be the distance between the ships, then we want to find dz/dt when $t = 4$ h.

$$(d) z^2 = (150 - x)^2 + y^2 \Rightarrow 2z \frac{dz}{dt} = 2(150 - x) \left(-\frac{dx}{dt} \right) + 2y \frac{dy}{dt}$$

(e) At 4:00 P.M., $x = 4(35) = 140$ and $y = 4(25) = 100 \Rightarrow z = \sqrt{(150 - 140)^2 + 100^2} = \sqrt{10,100}$. So

$$\frac{dz}{dt} = \frac{1}{z} \left[(x - 150) \frac{dx}{dt} + y \frac{dy}{dt} \right] = \frac{-10(35) + 100(25)}{\sqrt{10,100}} = \frac{215}{\sqrt{101}} \approx 21.4 \text{ km/h.}$$

11.

We are given that $\frac{dx}{dt} = 60$ mi/h and $\frac{dy}{dt} = 25$ mi/h. $z^2 = x^2 + y^2 \Rightarrow$

$$2z \frac{dz}{dt} = 2x \frac{dx}{dt} + 2y \frac{dy}{dt} \Rightarrow z \frac{dz}{dt} = x \frac{dx}{dt} + y \frac{dy}{dt} \Rightarrow \frac{dz}{dt} = \frac{1}{z} \left(x \frac{dx}{dt} + y \frac{dy}{dt} \right).$$

After 2 hours, $x = 2(60) = 120$ and $y = 2(25) = 50 \Rightarrow z = \sqrt{120^2 + 50^2} = 130$,

$$\text{so } \frac{dz}{dt} = \frac{1}{z} \left(x \frac{dx}{dt} + y \frac{dy}{dt} \right) = \frac{120(60) + 50(25)}{130} = 65 \text{ mi/h.}$$

12.

We are given that $\frac{dx}{dt} = 1.6$ m/s. By similar triangles, $\frac{y}{12} = \frac{2}{x} \Rightarrow y = \frac{24}{x}$

$$\Rightarrow \frac{dy}{dt} = -\frac{24}{x^2} \frac{dx}{dt} = -\frac{24}{x^2} (1.6). \text{ When } x = 8, \frac{dy}{dt} = -\frac{24(1.6)}{64} = -0.6 \text{ m/s,}$$

so the shadow is decreasing at a rate of 0.6 m/s.

13.

We are given that $\frac{dx}{dt} = 4$ ft/s and $\frac{dy}{dt} = 5$ ft/s. $z^2 = (x + y)^2 + 500^2 \Rightarrow$

$$2z \frac{dz}{dt} = 2(x + y) \left(\frac{dx}{dt} + \frac{dy}{dt} \right). \text{ 15 minutes after the woman starts, we have}$$

$$x = (4 \text{ ft/s})(20 \text{ min})(60 \text{ s/min}) = 4800 \text{ ft and } y = 5 \cdot 15 \cdot 60 = 4500 \Rightarrow$$

$$z = \sqrt{(4800 + 4500)^2 + 500^2} = \sqrt{86,740,000}, \text{ so}$$

$$\frac{dz}{dt} = \frac{x + y}{z} \left(\frac{dx}{dt} + \frac{dy}{dt} \right) = \frac{4800 + 4500}{\sqrt{86,740,000}} (4 + 5) = \frac{837}{\sqrt{8674}} \approx 8.99 \text{ ft/s.}$$

14. We are given that $\frac{dx}{dt} = 24$ ft/s.

(a)

$$y^2 = (90 - x)^2 + 90^2 \Rightarrow 2y \frac{dy}{dt} = 2(90 - x) \left(-\frac{dx}{dt} \right).$$

When $x = 45$, $y = \sqrt{45^2 + 90^2} = 45\sqrt{5}$, so

$$\frac{dy}{dt} = \frac{90 - x}{y} \left(-\frac{dx}{dt} \right) = \frac{45}{45\sqrt{5}} (-24) = -\frac{24}{\sqrt{5}},$$

so the distance from second base is decreasing at a rate of $\frac{24}{\sqrt{5}} \approx 10.7$ ft/s.

(b) Due to the symmetric nature of the problem in part (a), we expect to get the same answer—and we do.

$$z^2 = x^2 + 90^2 \Rightarrow 2z \frac{dz}{dt} = 2x \frac{dx}{dt}. \text{ When } x = 45, z = 45\sqrt{5}, \text{ so } \frac{dz}{dt} = \frac{45}{45\sqrt{5}} (24) = \frac{24}{\sqrt{5}} \approx 10.7 \text{ ft/s.}$$

15. $A = \frac{1}{2}bh$, where b is the base and h is the altitude. We are given that $\frac{dh}{dt} = 1$ cm/min and $\frac{dA}{dt} = 2$ cm²/min.

Using the Product Rule, we have $\frac{dA}{dt} = \frac{1}{2} \left(b \frac{dh}{dt} + h \frac{db}{dt} \right)$. When $h = 10$ and $A = 100$, we have

$$100 = \frac{1}{2}b(10) \Rightarrow \frac{1}{2}b = 10 \Rightarrow b = 20, \text{ so } 2 = \frac{1}{2} \left(20 \cdot 1 + 10 \frac{db}{dt} \right) \Rightarrow 4 = 20 + 10 \frac{db}{dt} \Rightarrow \frac{db}{dt} = \frac{4 - 20}{10} = -1.6 \text{ cm/min.}$$

16.

Given $\frac{dy}{dt} = -1$ m/s, find $\frac{dx}{dt}$ when $x = 8$ m. $y^2 = x^2 + 1 \Rightarrow$

$$2y \frac{dy}{dt} = 2x \frac{dx}{dt} \Rightarrow \frac{dx}{dt} = \frac{y}{x} \frac{dy}{dt} = -\frac{y}{x}. \text{ When } x = 8, y = \sqrt{65}, \text{ so}$$

$$\frac{dx}{dt} = -\frac{\sqrt{65}}{8}. \text{ Thus, the boat approaches the dock at } \frac{\sqrt{65}}{8} \approx 1.01 \text{ m/s.}$$

17.

We are given that $\frac{dx}{dt} = 35$ km/h and $\frac{dy}{dt} = 25$ km/h. $z^2 = (x + y)^2 + 100^2$

$$\Rightarrow 2z \frac{dz}{dt} = 2(x + y) \left(\frac{dx}{dt} + \frac{dy}{dt} \right). \text{ At 4:00 P.M., } x = 4(35) = 140 \text{ and}$$

$$y = 4(25) = 100 \Rightarrow z = \sqrt{(140 + 100)^2 + 100^2} = \sqrt{67,600} = 260, \text{ so}$$

$$\frac{dz}{dt} = \frac{x + y}{z} \left(\frac{dx}{dt} + \frac{dy}{dt} \right) = \frac{140 + 100}{260} (35 + 25) = \frac{720}{13} \approx 55.4 \text{ km/h.}$$

18. Let D denote the distance from the origin $(0, 0)$ to the point on the curve $y = \sqrt{x}$.

$$D = \sqrt{(x - 0)^2 + (y - 0)^2} = \sqrt{x^2 + (\sqrt{x})^2} = \sqrt{x^2 + x} \Rightarrow$$

$$\frac{dD}{dt} = \frac{1}{2}(x^2 + x)^{-1/2} (2x + 1) \frac{dx}{dt} = \frac{2x + 1}{2\sqrt{x^2 + x}} \frac{dx}{dt}. \text{ With } \frac{dx}{dt} = 3 \text{ when } x = 4,$$

$$\frac{dD}{dt} = \frac{9}{2\sqrt{20}} (3) = \frac{27}{4\sqrt{5}} \approx 3.02 \text{ cm/s.}$$

19.

If $C =$ the rate at which water is pumped in, then $\frac{dV}{dt} = C - 10,000$, where

$$V = \frac{1}{3}\pi r^2 h \text{ is the volume at time } t. \text{ By similar triangles, } \frac{r}{2} = \frac{h}{6} \Rightarrow$$

$$r = \frac{1}{3}h \Rightarrow V = \frac{1}{3}\pi \left(\frac{1}{3}h\right)^2 h = \frac{\pi}{27}h^3 \Rightarrow \frac{dV}{dt} = \frac{\pi}{9}h^2 \frac{dh}{dt}.$$

$$\text{When } h = 200 \text{ cm, } \frac{dh}{dt} = 20 \text{ cm/min, so } C - 10,000 = \frac{\pi}{9}(200)^2(20) \Rightarrow$$

$$C = 10,000 + \frac{800,000}{9}\pi \approx 289,253 \text{ cm}^3/\text{min.}$$

20.

By similar triangles, $\frac{3}{1} = \frac{b}{h}$, so $b = 3h$. The trough has volume

$$V = \frac{1}{2}bh(10) = 5(3h)h = 15h^2 \Rightarrow 12 = \frac{dV}{dt} = 30h \frac{dh}{dt} \Rightarrow$$

$$\frac{dh}{dt} = \frac{2}{5h}. \text{ When } h = \frac{1}{2}, \frac{dh}{dt} = \frac{2}{5 \cdot \frac{1}{2}} = \frac{4}{5} \text{ ft/min.}$$

21.

The figure is labeled in meters. The area A of a trapezoid is

$\frac{1}{2}(\text{base}_1 + \text{base}_2)(\text{height})$, and the volume V of the 10-meter-long trough is $10A$. Thus, the volume of the trapezoid with height h is

$V = (10)\frac{1}{2}[0.3 + (0.3 + 2a)]h$. By similar triangles, $\frac{a}{h} = \frac{0.25}{0.5} = \frac{1}{2}$, so

$$2a = h \Rightarrow V = 5(0.6 + h)h = 3h + 5h^2. \text{ Now } \frac{dV}{dt} = \frac{dV}{dh} \frac{dh}{dt} \Rightarrow 0.2 = (3 + 10h) \frac{dh}{dt} \Rightarrow$$

$$\frac{dh}{dt} = \frac{0.2}{3 + 10h}. \text{ When } h = 0.3, \frac{dh}{dt} = \frac{0.2}{3 + 10(0.3)} = \frac{0.2}{6} \text{ m/min} = \frac{1}{30} \text{ m/min or } \frac{10}{3} \text{ cm/min.}$$

22.

The figure is drawn without the top 3 feet.

$V = \frac{1}{2}(b + 12)h(20) = 10(b + 12)h$ and, from similar triangles,

$$\frac{x}{h} = \frac{6}{6} \text{ and } \frac{y}{h} = \frac{16}{6} = \frac{8}{3}, \text{ so } b = x + 12 + y = h + 12 + \frac{8h}{3} = 12 + \frac{11h}{3}. \text{ Thus,}$$

$$V = 10\left(24 + \frac{11h}{3}\right)h = 240h + \frac{110h^2}{3} \text{ and so } 0.8 = \frac{dV}{dt} = \left(240 + \frac{220}{3}h\right) \frac{dh}{dt}. \text{ When } h = 5,$$

$$\frac{dh}{dt} = \frac{0.8}{240 + 5(220/3)} = \frac{3}{2275} \approx 0.00132 \text{ ft/min.}$$

23.

We are given that $\frac{dV}{dt} = 30 \text{ ft}^3/\text{min}$. $V = \frac{1}{3}\pi r^2 h = \frac{1}{3}\pi \left(\frac{h}{2}\right)^2 h = \frac{\pi h^3}{12}$

$$\Rightarrow \frac{dV}{dt} = \frac{dV}{dh} \frac{dh}{dt} \Rightarrow 30 = \frac{\pi h^2}{4} \frac{dh}{dt} \Rightarrow \frac{dh}{dt} = \frac{120}{\pi h^2}. \text{ When}$$

$$h = 10 \text{ ft, } \frac{dh}{dt} = \frac{120}{10^2 \pi} = \frac{6}{5\pi} \approx 0.38 \text{ ft/min.}$$

24.

We are given $dx/dt = 8 \text{ ft/s}$. $\cot \theta = \frac{x}{100} \Rightarrow x = 100 \cot \theta \Rightarrow$

$$\frac{dx}{dt} = -100 \csc^2 \theta \frac{d\theta}{dt} \Rightarrow \frac{d\theta}{dt} = -\frac{\sin^2 \theta}{100} \cdot 8. \text{ When } y = 200,$$

$$\sin \theta = \frac{100}{200} = \frac{1}{2} \Rightarrow \frac{d\theta}{dt} = -\frac{(1/2)^2}{100} \cdot 8 = -\frac{1}{50} \text{ rad/s. The angle is decreasing at a rate of } \frac{1}{50} \text{ rad/s.}$$

25.

$A = \frac{1}{2}bh$, but $b = 5 \text{ m}$ and $\sin \theta = \frac{h}{4} \Rightarrow h = 4 \sin \theta$, so

$A = \frac{1}{2}(5)(4 \sin \theta) = 10 \sin \theta$. We are given $\frac{d\theta}{dt} = 0.06 \text{ rad/s}$, so

$$\frac{dA}{dt} = \frac{dA}{d\theta} \frac{d\theta}{dt} = (10 \cos \theta)(0.06) = 0.6 \cos \theta. \text{ When } \theta = \frac{\pi}{3},$$

$$\frac{dA}{dt} = 0.6\left(\cos \frac{\pi}{3}\right) = (0.6)\left(\frac{1}{2}\right) = 0.3 \text{ m}^2/\text{s}.$$

26.

We are given $d\theta/dt = 2^\circ/\text{min} = \frac{\pi}{90}$ rad/min. By the Law of Cosines,

$$x^2 = 12^2 + 15^2 - 2(12)(15) \cos \theta = 369 - 360 \cos \theta \Rightarrow$$

$$2x \frac{dx}{dt} = 360 \sin \theta \frac{d\theta}{dt} \Rightarrow \frac{dx}{dt} = \frac{180 \sin \theta}{x} \frac{d\theta}{dt}. \text{ When } \theta = 60^\circ,$$

$$x = \sqrt{369 - 360 \cos 60^\circ} = \sqrt{189} = 3\sqrt{21}, \text{ so}$$

$$\frac{dx}{dt} = \frac{180 \sin 60^\circ}{3\sqrt{21}} \frac{\pi}{90} = \frac{\pi \sqrt{3}}{3\sqrt{21}} = \frac{\sqrt{7}\pi}{21} \approx 0.396 \text{ m/min.}$$

27. Differentiating both sides of $PV = C$ with respect to t and using the Product Rule gives us $P \frac{dV}{dt} + V \frac{dP}{dt} = 0$

$\Rightarrow \frac{dV}{dt} = -\frac{V}{P} \frac{dP}{dt}$. When $V = 600$, $P = 150$ and $\frac{dP}{dt} = 20$, so we have $\frac{dV}{dt} = -\frac{600}{150}(20) = -80$. Thus, the volume is decreasing at a rate of $80 \text{ cm}^3/\text{min}$.

28. $PV^{1.4} = C \Rightarrow P \cdot 1.4V^{0.4} \frac{dV}{dt} + V^{1.4} \frac{dP}{dt} = 0 \Rightarrow \frac{dV}{dt} = -\frac{V^{1.4}}{P \cdot 1.4V^{0.4}} \frac{dP}{dt} = -\frac{V}{1.4P} \frac{dP}{dt}$. When

$V = 400$, $P = 80$ and $\frac{dP}{dt} = -10$, so we have $\frac{dV}{dt} = -\frac{400}{1.4(80)}(-10) = \frac{250}{7}$. Thus, the volume is increasing at a rate of $\frac{250}{7} \approx 36 \text{ cm}^3/\text{min}$.

29. With $R_1 = 80$ and $R_2 = 100$, $\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2} = \frac{1}{80} + \frac{1}{100} = \frac{180}{8000} = \frac{9}{400}$, so $R = \frac{400}{9}$. Differentiating

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2} \text{ with respect to } t, \text{ we have } -\frac{1}{R^2} \frac{dR}{dt} = -\frac{1}{R_1^2} \frac{dR_1}{dt} - \frac{1}{R_2^2} \frac{dR_2}{dt} \Rightarrow$$

$$\frac{dR}{dt} = R^2 \left(\frac{1}{R_1^2} \frac{dR_1}{dt} + \frac{1}{R_2^2} \frac{dR_2}{dt} \right). \text{ When } R_1 = 80 \text{ and } R_2 = 100,$$

$$\frac{dR}{dt} = \frac{400^2}{9^2} \left[\frac{1}{80^2}(0.3) + \frac{1}{100^2}(0.2) \right] = \frac{107}{810} \approx 0.132 \Omega/\text{s}.$$

30. We want to find $\frac{dB}{dt}$ when $L = 18$ using $B = 0.007W^{2/3}$ and $W = 0.12L^{2.53}$.

$$\frac{dB}{dt} = \frac{dB}{dW} \frac{dW}{dL} \frac{dL}{dt} = \left(0.007 \cdot \frac{2}{3} W^{-1/3} \right) (0.12 \cdot 2.53 \cdot L^{1.53}) \left(\frac{20 - 15}{10,000,000} \right)$$

$$= \left[0.007 \cdot \frac{2}{3} (0.12 \cdot 18^{2.53})^{-1/3} \right] (0.12 \cdot 2.53 \cdot 18^{1.53}) \left(\frac{5}{10^7} \right) \approx 1.045 \times 10^{-8} \text{ g/yr}$$

31.

We are given that $\frac{dx}{dt} = 2 \text{ ft/s}$. $\sin \theta = \frac{x}{10} \Rightarrow x = 10 \sin \theta \Rightarrow$

$$\frac{dx}{dt} = 10 \cos \theta \frac{d\theta}{dt}. \text{ When } \theta = \frac{\pi}{4}, 2 = 10 \cos \frac{\pi}{4} \frac{d\theta}{dt} \Rightarrow$$

$$\frac{d\theta}{dt} = \frac{2}{10(1/\sqrt{2})} = \frac{\sqrt{2}}{5} \text{ rad/s.}$$

32.

Using Q for the origin, we are given $\frac{dx}{dt} = -2$ ft/s and need to find $\frac{dy}{dt}$ when $x = -5$. Using the Pythagorean Theorem twice, we have

$\sqrt{x^2 + 12^2} + \sqrt{y^2 + 12^2} = 39$, the total length of the rope. Differentiating

with respect to t , we get $\frac{x}{\sqrt{x^2 + 12^2}} \frac{dx}{dt} + \frac{y}{\sqrt{y^2 + 12^2}} \frac{dy}{dt} = 0$, so

$$\frac{dy}{dt} = -\frac{x \sqrt{y^2 + 12^2}}{y \sqrt{x^2 + 12^2}} \frac{dx}{dt}. \text{ Now when } x = -5, 39 = \sqrt{(-5)^2 + 12^2} + \sqrt{y^2 + 12^2} = 13 + \sqrt{y^2 + 12^2} \Leftrightarrow$$

$$\sqrt{y^2 + 12^2} = 26, \text{ and } y = \sqrt{26^2 - 12^2} = \sqrt{532}. \text{ So when } x = -5,$$

$$\frac{dy}{dt} = -\frac{(-5)(26)}{\sqrt{532}(13)}(-2) = -\frac{10}{\sqrt{133}} \approx -0.87 \text{ ft/s. So cart B is moving towards Q at about 0.87 ft/s.}$$

33. (a)

By the Pythagorean Theorem, $4000^2 + y^2 = \ell^2$. Differentiating with respect to t , we obtain $2y \frac{dy}{dt} = 2\ell \frac{d\ell}{dt}$. We know that $\frac{dy}{dt} = 600$ ft/s, so when

$$y = 3000 \text{ ft}, \ell = \sqrt{4000^2 + 3000^2} = \sqrt{25,000,000} = 5000 \text{ ft and}$$

$$\frac{d\ell}{dt} = \frac{y}{\ell} \frac{dy}{dt} = \frac{3000}{5000}(600) = \frac{1800}{5} = 360 \text{ ft/s.}$$

$$(b) \text{ Here } \tan \theta = \frac{y}{4000} \Rightarrow \frac{d}{dt}(\tan \theta) = \frac{d}{dt}\left(\frac{y}{4000}\right) \Rightarrow \sec^2 \theta \frac{d\theta}{dt} = \frac{1}{4000} \frac{dy}{dt} \Rightarrow \frac{d\theta}{dt} = \frac{\cos^2 \theta}{4000} \frac{dy}{dt}.$$

$$\text{When } y = 3000 \text{ ft, } \frac{dy}{dt} = 600 \text{ ft/s, } \ell = 5000 \text{ and } \cos \theta = \frac{4000}{\ell} = \frac{4000}{5000} = \frac{4}{5}, \text{ so}$$

$$\frac{d\theta}{dt} = \frac{(4/5)^2}{4000}(600) = 0.096 \text{ rad/s.}$$

34.

We are given that $\frac{d\theta}{dt} = 4(2\pi) = 8\pi$ rad/min. $x = 3 \tan \theta \Rightarrow$

$$\frac{dx}{dt} = 3 \sec^2 \theta \frac{d\theta}{dt}. \text{ When } x = 1, \tan \theta = \frac{1}{3}, \text{ so } \sec^2 \theta = 1 + \left(\frac{1}{3}\right)^2 = \frac{10}{9} \text{ and}$$

$$\frac{dx}{dt} = 3\left(\frac{10}{9}\right)(8\pi) = \frac{80\pi}{3} \approx 83.8 \text{ km/min.}$$

35.

We are given that $\frac{dx}{dt} = 300$ km/h. By the Law of Cosines,

$$y^2 = x^2 + 1^2 - 2(1)(x) \cos 120^\circ = x^2 + 1 - 2x\left(-\frac{1}{2}\right) = x^2 + x + 1, \text{ so}$$

$$2y \frac{dy}{dt} = 2x \frac{dx}{dt} + \frac{dx}{dt} \Rightarrow \frac{dy}{dt} = \frac{2x + 1}{2y} \frac{dx}{dt}. \text{ After 1 minute,}$$

$$x = \frac{300}{60} = 5 \text{ km} \Rightarrow y = \sqrt{5^2 + 5 + 1} = \sqrt{31} \text{ km} \Rightarrow$$

$$\frac{dy}{dt} = \frac{2(5) + 1}{2\sqrt{31}}(300) = \frac{1650}{\sqrt{31}} \approx 296 \text{ km/h.}$$

36.

We are given that $\frac{dx}{dt} = 3$ mi/h and $\frac{dy}{dt} = 2$ mi/h. By the Law of Cosines,

$$z^2 = x^2 + y^2 - 2xy \cos 45^\circ = x^2 + y^2 - \sqrt{2}xy \Rightarrow$$

$$2z \frac{dz}{dt} = 2x \frac{dx}{dt} + 2y \frac{dy}{dt} - \sqrt{2}x \frac{dy}{dt} - \sqrt{2}y \frac{dx}{dt}. \text{ After 15 minutes } [= \frac{1}{4} \text{ h}],$$

$$\text{we have } x = \frac{3}{4} \text{ and } y = \frac{2}{4} = \frac{1}{2} \Rightarrow z^2 = \left(\frac{3}{4}\right)^2 + \left(\frac{1}{2}\right)^2 - \sqrt{2}\left(\frac{3}{4}\right)\left(\frac{1}{2}\right) \Rightarrow z = \frac{\sqrt{13 - 6\sqrt{2}}}{4} \text{ and}$$

$$\frac{dz}{dt} = \frac{2}{\sqrt{13 - 6\sqrt{2}}} \left[2\left(\frac{3}{4}\right)3 + 2\left(\frac{1}{2}\right)2 - \sqrt{2}\left(\frac{3}{4}\right)2 - \sqrt{2}\left(\frac{1}{2}\right)3 \right] = \frac{2}{\sqrt{13 - 6\sqrt{2}}} \frac{13 - 6\sqrt{2}}{2} = \sqrt{13 - 6\sqrt{2}} \\ \approx 2.125 \text{ mi/h.}$$

37.

Let the distance between the runner and the friend be ℓ . Then by the Law of Cosines,

$$\ell^2 = 200^2 + 100^2 - 2 \cdot 200 \cdot 100 \cdot \cos \theta = 50,000 - 40,000 \cos \theta (*).$$

Differentiating implicitly with respect to t , we obtain

$$2\ell \frac{d\ell}{dt} = -40,000(-\sin \theta) \frac{d\theta}{dt}. \text{ Now if } D \text{ is the distance run when}$$

the angle is θ radians, then by the formula for the length of an arc on a circle, $s = r\theta$, we have $D = 100\theta$, so

$$\theta = \frac{1}{100}D \Rightarrow \frac{d\theta}{dt} = \frac{1}{100} \frac{dD}{dt} = \frac{7}{100}. \text{ To substitute into the expression for } \frac{d\ell}{dt}, \text{ we must know } \sin \theta \text{ at the time}$$

$$\text{when } \ell = 200, \text{ which we find from } (*): 200^2 = 50,000 - 40,000 \cos \theta \Leftrightarrow \cos \theta = \frac{1}{4} \Rightarrow$$

$$\sin \theta = \sqrt{1 - \left(\frac{1}{4}\right)^2} = \frac{\sqrt{15}}{4}. \text{ Substituting, we get } 2(200) \frac{d\ell}{dt} = 40,000 \frac{\sqrt{15}}{4} \left(\frac{7}{100}\right) \Rightarrow$$

$$d\ell/dt = \frac{7\sqrt{15}}{4} \approx 6.78 \text{ m/s. Whether the distance between them is increasing or decreasing depends on the direction in which the runner is running.}$$

38.

The hour hand of a clock goes around once every 12 hours or, in radians per hour, $\frac{2\pi}{12} = \frac{\pi}{6}$ rad/h. The minute hand goes around once an hour, or at the rate of 2π rad/h. So the angle θ between them (measuring clockwise from the minute hand to the hour hand) is changing at the rate of

$$d\theta/dt = \frac{\pi}{6} - 2\pi = -\frac{11\pi}{6} \text{ rad/h. Now, to relate } \theta \text{ to } \ell, \text{ we use the Law of}$$

$$\text{Cosines: } \ell^2 = 4^2 + 8^2 - 2 \cdot 4 \cdot 8 \cdot \cos \theta = 80 - 64 \cos \theta (*).$$

Differentiating implicitly with respect to t , we get $2\ell \frac{d\ell}{dt} = -64(-\sin \theta) \frac{d\theta}{dt}$. At 1:00, the angle between the two hands is one-twelfth of the circle, that is, $\frac{2\pi}{12} = \frac{\pi}{6}$ radians. We use (*) to find ℓ at 1:00:

$$\ell = \sqrt{80 - 64 \cos \frac{\pi}{6}} = \sqrt{80 - 32\sqrt{3}}. \text{ Substituting, we get } 2\ell \frac{d\ell}{dt} = 64 \sin \frac{\pi}{6} \left(-\frac{11\pi}{6}\right) \Rightarrow$$

$$\frac{d\ell}{dt} = \frac{64\left(\frac{1}{2}\right)\left(-\frac{11\pi}{6}\right)}{2\sqrt{80 - 32\sqrt{3}}} = -\frac{88\pi}{3\sqrt{80 - 32\sqrt{3}}} \approx -18.6. \text{ So at 1:00, the distance between the tips of the hands is}$$

$$\text{decreasing at a rate of } 18.6 \text{ mm/h} \approx 0.005 \text{ mm/s.}$$

3.10 Linear Approximations and Differentials

1. As in Example 1, $T(0) = 185$, $T(10) = 172$, $T(20) = 160$, and

$$T'(20) \approx \frac{T(10) - T(20)}{10 - 20} = \frac{172 - 160}{-10} = -1.2^\circ\text{F/min.}$$

$$T(30) \approx T(20) + T'(20)(30 - 20) \approx 160 - 1.2(10) = 148^\circ\text{F.}$$

We would expect the temperature of the turkey to get closer to 75°F as time increases. Since the temperature decreased 13°F in the first 10 minutes and 12°F in the second 10 minutes, we can assume that the slopes of the tangent line are increasing through negative values:

$-1.3, -1.2, \dots$. Hence, the tangent lines are under the curve and 148°F

is an underestimate. From the figure, we estimate the slope of the tangent line at $t = 20$ to be $\frac{184 - 147}{0 - 30} = -\frac{37}{30}$.

Then the linear approximation becomes $T(30) \approx T(20) + T'(20) \cdot 10 \approx 160 - \frac{37}{30}(10) = 147\frac{2}{3} \approx 147.7$.

2. $P'(2) \approx \frac{P(1) - P(2)}{1 - 2} = \frac{87.1 - 74.9}{-1} = -12.2$ kilopascals/km.

$$P(3) \approx P(2) + P'(2)(3 - 2) \approx 74.9 - 12.2(1) = 62.7 \text{ kPa.}$$

From the figure, we estimate the slope of the tangent line at $h = 2$ to be

$$\frac{98 - 63}{0 - 3} = -\frac{35}{3}. \text{ Then the linear approximation becomes}$$

$$P(3) \approx P(2) + P'(2) \cdot 1 \approx 74.9 - \frac{35}{3} \approx 63.23 \text{ kPa.}$$

3. Extend the tangent line at the point $(2030, 21)$ to the t -axis.

Answers will vary based on this approximation—we'll use

$t = 1900$ as our t -intercept. The linearization is then

$$\begin{aligned} P(t) &\approx P(2030) + P'(2030)(t - 2030) \\ &\approx 21 + \frac{21}{130}(t - 2030) \end{aligned}$$

$$P(2040) = 21 + \frac{21}{130}(2040 - 2030) \approx 22.6\%$$

$$P(2050) = 21 + \frac{21}{130}(2050 - 2030) \approx 24.2\%$$

These predictions are probably too high since the tangent line lies above the graph at $t = 2030$.

4. Let $A = \frac{N(1980) - N(1985)}{1980 - 1985} = \frac{15.0 - 17.0}{-5} = 0.4$ and $B = \frac{N(1990) - N(1985)}{1990 - 1985} = \frac{19.3 - 17.0}{5} = 0.46$.

$$\text{Then } N'(1985) = \lim_{t \rightarrow 1985} \frac{N(t) - N(1985)}{t - 1985} \approx \frac{A + B}{2} = 0.43 \text{ million/year. So}$$

$$N(1984) \approx N(1985) + N'(1985)(1984 - 1985) \approx 17.0 + 0.43(-1) = 16.57 \text{ million.}$$

$$N'(2000) \approx \frac{N(1995) - N(2000)}{1995 - 2000} = \frac{22.0 - 24.9}{-5} = 0.58 \text{ million/year.}$$

$$N(2006) \approx N(2000) + N'(2000)(2006 - 2000) \approx 24.9 + 0.58(6) = 28.38 \text{ million.}$$

5. $f(x) = x^3 \Rightarrow f'(x) = 3x^2$, so $f(1) = 1$ and $f'(1) = 3$. With $a = 1$, $L(x) = f(a) + f'(a)(x - a)$ becomes $L(x) = f(1) + f'(1)(x - 1) = 1 + 3(x - 1) = 3x - 2$.

6. $f(x) = 1/\sqrt{2+x} = (2+x)^{-1/2} \Rightarrow f'(x) = -\frac{1}{2}(2+x)^{-3/2}$ so $f(0) = \frac{1}{\sqrt{2}}$ and $f'(0) = -1/(4\sqrt{2})$. So $L(x) = f(0) + f'(0)(x - 0) = \frac{1}{\sqrt{2}} - \frac{1}{4\sqrt{2}}(x - 0) = \frac{1}{\sqrt{2}}(1 - \frac{1}{4}x)$.

7. $f(x) = \cos x \Rightarrow f'(x) = -\sin x$, so $f(\frac{\pi}{2}) = 0$ and $f'(\frac{\pi}{2}) = -1$. Thus, $L(x) = f(\frac{\pi}{2}) + f'(\frac{\pi}{2})(x - \frac{\pi}{2}) = 0 - 1(x - \frac{\pi}{2}) = -x + \frac{\pi}{2}$.

8. $f(x) = \sqrt[3]{x} = x^{1/3} \Rightarrow f'(x) = \frac{1}{3}x^{-2/3}$, so $f(-8) = -2$ and $f'(-8) = \frac{1}{12}$. Thus, $L(x) = f(-8) + f'(-8)(x + 8) = -2 + \frac{1}{12}(x + 8) = \frac{1}{12}x - \frac{4}{3}$.

9. $f(x) = \sqrt{1-x} \Rightarrow f'(x) = \frac{-1}{2\sqrt{1-x}}$, so $f(0) = 1$ and $f'(0) = -\frac{1}{2}$. Therefore,

$$\begin{aligned}\sqrt{1-x} = f(x) &\approx f(0) + f'(0)(x - 0) \\ &= 1 + (-\frac{1}{2})(x - 0) = 1 - \frac{1}{2}x\end{aligned}$$

So $\sqrt{0.9} = \sqrt{1-0.1} \approx 1 - \frac{1}{2}(0.1) = 0.95$ and

$\sqrt{0.99} = \sqrt{1-0.01} \approx 1 - \frac{1}{2}(0.01) = 0.995$.

10. $g(x) = \sqrt[3]{1+x} = (1+x)^{1/3} \Rightarrow g'(x) = \frac{1}{3}(1+x)^{-2/3}$, so $g(0) = 1$ and $g'(0) = \frac{1}{3}$.

Therefore, $\sqrt[3]{1+x} = g(x) \approx g(0) + g'(0)(x - 0) = 1 + \frac{1}{3}x$.

So $\sqrt[3]{0.95} = \sqrt[3]{1+(-0.05)} \approx 1 + \frac{1}{3}(-0.05) = 0.98\bar{3}$, and

$\sqrt[3]{1.1} = \sqrt[3]{1+0.1} \approx 1 + \frac{1}{3}(0.1) = 1.0\bar{3}$.

11. $f(x) = \sqrt[3]{1-x} = (1-x)^{1/3} \Rightarrow f'(x) = -\frac{1}{3}(1-x)^{-2/3}$, so $f(0) = 1$ and $f'(0) = -\frac{1}{3}$. Thus,

$f(x) \approx f(0) + f'(0)(x - 0) = 1 - \frac{1}{3}x$. We need

$\sqrt[3]{1-x} - 0.1 < 1 - \frac{1}{3}x < \sqrt[3]{1-x} + 0.1$, which is true when $-1.204 < x < 0.706$.

12. $f(x) = \tan x \Rightarrow f'(x) = \sec^2 x$, so $f(0) = 0$ and $f'(0) = 1$.

Thus, $f(x) \approx f(0) + f'(0)(x - 0) = 0 + 1(x - 0) = x$.

We need $\tan x - 0.1 < x < \tan x + 0.1$, which is true when

$-0.63 < x < 0.63$.

$$13. f(x) = \frac{1}{(1+2x)^4} = (1+2x)^{-4} \Rightarrow$$

$$f'(x) = -4(1+2x)^{-5}(2) = \frac{-8}{(1+2x)^5}, \text{ so } f(0) = 1 \text{ and } f'(0) = -8.$$

$$\text{Thus, } f(x) \approx f(0) + f'(0)(x-0) = 1 + (-8)(x-0) = 1 - 8x.$$

We need $1/(1+2x)^4 - 0.1 < 1 - 8x < 1/(1+2x)^4 + 0.1$, which is true when $-0.045 < x < 0.055$.

$$14. f(x) = \frac{1}{\sqrt{4-x}} \Rightarrow f'(x) = \frac{1}{2(4-x)^{3/2}} \text{ so } f(0) = \frac{1}{2} \text{ and}$$

$$f'(0) = \frac{1}{16}. \text{ So } f(x) \approx \frac{1}{2} + \frac{1}{16}(x-0) = \frac{1}{2} + \frac{1}{16}x. \text{ We need}$$

$$\frac{1}{\sqrt{4-x}} - 0.1 < \frac{1}{2} + \frac{1}{16}x < \frac{1}{\sqrt{4-x}} + 0.1, \text{ which is true when } -3.91 < x < 2.14.$$

$$15. \text{ If } y = f(x), \text{ then the differential } dy \text{ is equal to } f'(x) dx. y = x^4 + 5x \Rightarrow dy = (4x^3 + 5) dx.$$

$$16. y = \cos \pi x \Rightarrow dy = -\sin \pi x \cdot \pi dx = -\pi \sin \pi x dx$$

$$17. y = x^2 \tan x \Rightarrow dy = (x^2 \sec^2 x + \tan x \cdot 2x) dx = (x^2 \sec^2 x + 2x \tan x) dx$$

$$18. y = \sqrt{1+t^2} \Rightarrow dy = \frac{1}{2}(1+t^2)^{-1/2}(2t) dt = \frac{t}{\sqrt{1+t^2}} dt$$

$$19. y = \frac{u+1}{u-1} \Rightarrow dy = \frac{(u-1)(1) - (u+1)(1)}{(u-1)^2} du = \frac{-2}{(u-1)^2} du$$

$$20. y = (1+2r)^{-4} \Rightarrow dy = -4(1+2r)^{-5} \cdot 2 dr = -8(1+2r)^{-5} dr$$

$$21. (a) y = x^2 + 2x \Rightarrow dy = (2x+2) dx$$

$$(b) \text{ When } x = 3 \text{ and } dx = \frac{1}{2}, dy = [2(3) + 2] \left(\frac{1}{2}\right) = 4.$$

$$22. (a) y = x^3 - 6x^2 + 5x - 7 \Rightarrow dy = (3x^2 - 12x + 5) dx$$

$$(b) \text{ When } x = -2 \text{ and } dx = 0.1, dy = (12 + 24 + 5)(0.1) = 4.1.$$

$$23. (a) y = \sqrt{4+5x} \Rightarrow dy = \frac{1}{2}(4+5x)^{-1/2} \cdot 5 dx = \frac{5}{2\sqrt{4+5x}} dx$$

$$(b) \text{ When } x = 0 \text{ and } dx = 0.04, dy = \frac{5}{2\sqrt{4}}(0.04) = \frac{5}{4} \cdot \frac{1}{25} = \frac{1}{20} = 0.05.$$

$$24. (a) y = 1/(x+1) \Rightarrow dy = -\frac{1}{(x+1)^2} dx$$

$$(b) \text{ When } x = 1 \text{ and } dx = -0.01, dy = -\frac{1}{2^2}(-0.01) = \frac{1}{4} \cdot \frac{1}{100} = \frac{1}{400} = 0.0025.$$

$$25. (a) y = \tan x \Rightarrow dy = \sec^2 x dx$$

$$(b) \text{ When } x = \pi/4 \text{ and } dx = -0.1, dy = [\sec(\pi/4)]^2(-0.1) = (\sqrt{2})^2(-0.1) = -0.2.$$

$$26. (a) y = \cos x \Rightarrow dy = -\sin x dx$$

$$(b) \text{ When } x = \pi/3 \text{ and } dx = 0.05, dy = -\sin(\pi/3)(0.05) = -0.5\sqrt{3}(0.05) = -0.025\sqrt{3} \approx -0.043.$$

$$27. y = x^2, x = 1, \Delta x = 0.5 \Rightarrow$$

$$\Delta y = (1.5)^2 - 1^2 = 1.25.$$

$$dy = 2x dx = 2(1)(0.5) = 1$$

$$28. y = \sqrt{x}, x = 1, \Delta x = 1 \Rightarrow$$

$$\Delta y = \sqrt{2} - \sqrt{1} = \sqrt{2} - 1 \approx 0.414$$

$$dy = \frac{1}{2\sqrt{x}} dx = \frac{1}{2}(1) = 0.5$$

$$29. y = 6 - x^2, x = -2, \Delta x = 0.4 \Rightarrow$$

$$\Delta y = (6 - (-1.6)^2) - (6 - (-2)^2) = 1.44$$

$$dy = -2x dx = -2(-2)(0.4) = 1.6$$

$$30. y = \frac{16}{x}, x = 4, \Delta x = -1 \Rightarrow$$

$$\Delta y = \frac{16}{3} - \frac{16}{4} = \frac{4}{3}.$$

$$dy = -\left(\frac{16}{x^2}\right) dx = -\left(\frac{16}{4^2}\right)(-1) = 1$$

$$31. y = f(x) = x^5 \Rightarrow dy = 5x^4 dx. \text{ When } x = 2 \text{ and } dx = 0.001, dy = 5(2)^4(0.001) = 0.08, \text{ so}$$

$$(2.001)^5 = f(2.001) \approx f(2) + dy = 32 + 0.08 = 32.08.$$

$$32. y = f(x) = \sqrt{x} \Rightarrow dy = \frac{1}{2\sqrt{x}} dx. \text{ When } x = 100 \text{ and } dx = -0.2, dy = \frac{1}{2\sqrt{100}}(-0.2) = -0.01, \text{ so}$$

$$\sqrt{99.8} = f(99.8) \approx f(100) + dy = 10 - 0.01 = 9.99.$$

$$33. y = f(x) = x^{2/3} \Rightarrow dy = \frac{2}{3\sqrt[3]{x}} dx. \text{ When } x = 8 \text{ and } dx = 0.06, dy = \frac{2}{3\sqrt[3]{8}}(0.06) = 0.02, \text{ so}$$

$$(8.06)^{2/3} = f(8.06) \approx f(8) + dy = 4 + 0.02 = 4.02.$$

$$34. y = f(x) = 1/x \Rightarrow dy = (-1/x^2) dx. \text{ When } x = 1000 \text{ and } dx = 2, dy = [-1/(1000)^2](2) = -0.000002, \text{ so}$$

$$1/1002 = f(1002) \approx f(1000) + dy = 1/1000 - 0.000002 = 0.000998$$

$$35. y = f(x) = \tan x \Rightarrow dy = \sec^2 x dx. \text{ When } x = 45^\circ \text{ and } dx = -1^\circ,$$

$$dy = \sec^2 45^\circ(-\pi/180) = (\sqrt{2})^2(-\pi/180) = -\pi/90, \text{ so}$$

$$\tan 44^\circ = f(44^\circ) \approx f(45^\circ) + dy = 1 - \pi/90 \approx 0.965.$$

$$36. y = f(x) = \cos x \Rightarrow dy = -\sin x dx. \text{ When } x = \frac{\pi}{6} \text{ and } dx = \frac{1.5\pi}{180},$$

$$dy = -\sin \frac{\pi}{6} \left(\frac{1.5\pi}{180}\right) = -\frac{1}{2} \left(\frac{\pi}{120}\right) = -\frac{\pi}{240}, \text{ so } \cos 31.5^\circ = f\left(\frac{31.5\pi}{180}\right) \approx f\left(\frac{\pi}{6}\right) + dy = \frac{\sqrt{3}}{2} - \frac{\pi}{240} \approx 0.853.$$

37. $y = f(x) = \sec x \Rightarrow f'(x) = \sec x \tan x$, so $f(0) = 1$ and $f'(0) = 1 \cdot 0 = 0$. The linear approximation of f at 0 is $f(0) + f'(0)(x - 0) = 1 + 0(x) = 1$. Since 0.08 is close to 0, approximating $\sec 0.08$ with 1 is reasonable.
38. If $y = x^6$, $y' = 6x^5$ and the tangent line approximation at $(1, 1)$ has slope 6. If the change in x is 0.01, the change in y on the tangent line is 0.06, and approximating $(1.01)^6$ with 1.06 is reasonable.
39. (a) If x is the edge length, then $V = x^3 \Rightarrow dV = 3x^2 dx$. When $x = 30$ and $dx = 0.1$,
 $dV = 3(30)^2(0.1) = 270$, so the maximum possible error in computing the volume of the cube is about 270 cm^3 . The relative error is calculated by dividing the change in V , ΔV , by V . We approximate ΔV with dV .
 Relative error $= \frac{\Delta V}{V} \approx \frac{dV}{V} = \frac{3x^2 dx}{x^3} = 3 \frac{dx}{x} = 3 \left(\frac{0.1}{30} \right) = 0.01$.
 Percentage error $= \text{relative error} \times 100\% = 0.01 \times 100\% = 1\%$.
- (b) $S = 6x^2 \Rightarrow dS = 12x dx$. When $x = 30$ and $dx = 0.1$, $dS = 12(30)(0.1) = 36$, so the maximum possible error in computing the surface area of the cube is about 36 cm^2 .
 Relative error $= \frac{\Delta S}{S} \approx \frac{dS}{S} = \frac{12x dx}{6x^2} = 2 \frac{dx}{x} = 2 \left(\frac{0.1}{30} \right) = 0.00\bar{6}$.
 Percentage error $= \text{relative error} \times 100\% = 0.00\bar{6} \times 100\% = 0.\bar{6}\%$.
40. (a) $A = \pi r^2 \Rightarrow dA = 2\pi r dr$. When $r = 24$ and $dr = 0.2$, $dA = 2\pi(24)(0.2) = 9.6\pi$, so the maximum possible error in the calculated area of the disk is about $9.6\pi \approx 30 \text{ cm}^2$.
- (b) Relative error $= \frac{\Delta A}{A} \approx \frac{dA}{A} = \frac{2\pi r dr}{\pi r^2} = \frac{2 dr}{r} = \frac{2(0.2)}{24} = \frac{0.2}{12} = \frac{1}{60} = 0.01\bar{6}$.
 Percentage error $= \text{relative error} \times 100\% = 0.01\bar{6} \times 100\% = 1.\bar{6}\%$.
41. (a) For a sphere of radius r , the circumference is $C = 2\pi r$ and the surface area is $S = 4\pi r^2$, so $r = C/(2\pi) \Rightarrow$
 $S = 4\pi(C/2\pi)^2 = C^2/\pi \Rightarrow dS = (2/\pi)C dC$. When $C = 84$ and $dC = 0.5$, $dS = \frac{2}{\pi}(84)(0.5) = \frac{84}{\pi}$,
 so the maximum error is about $\frac{84}{\pi} \approx 27 \text{ cm}^2$. Relative error $\approx \frac{dS}{S} = \frac{84/\pi}{84^2/\pi} = \frac{1}{84} \approx 0.012$
- (b) $V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi \left(\frac{C}{2\pi} \right)^3 = \frac{C^3}{6\pi^2} \Rightarrow dV = \frac{1}{2\pi^2} C^2 dC$. When $C = 84$ and $dC = 0.5$,
 $dV = \frac{1}{2\pi^2}(84)^2(0.5) = \frac{1764}{\pi^2}$, so the maximum error is about $\frac{1764}{\pi^2} \approx 179 \text{ cm}^3$. The relative error is
 approximately $\frac{dV}{V} = \frac{1764/\pi^2}{(84)^3/(6\pi^2)} = \frac{1}{56} \approx 0.018$.
42. For a hemispherical dome, $V = \frac{2}{3}\pi r^3 \Rightarrow dV = 2\pi r^2 dr$. When $r = \frac{1}{2}(50) = 25 \text{ m}$ and
 $dr = 0.05 \text{ cm} = 0.0005 \text{ m}$, $dV = 2\pi(25)^2(0.0005) = \frac{5\pi}{8}$, so the amount of paint needed is about $\frac{5\pi}{8} \approx 2 \text{ m}^3$.
43. (a) $V = \pi r^2 h \Rightarrow \Delta V \approx dV = 2\pi r h dr = 2\pi r h \Delta r$
- (b) The error is
 $\Delta V - dV = [\pi(r + \Delta r)^2 h - \pi r^2 h] - 2\pi r h \Delta r = \pi r^2 h + 2\pi r h \Delta r + \pi(\Delta r)^2 h - \pi r^2 h - 2\pi r h \Delta r$
 $= \pi(\Delta r)^2 h$
44. $F = kR^4 \Rightarrow dF = 4kR^3 dR \Rightarrow \frac{dF}{F} = \frac{4kR^3 dR}{kR^4} = 4 \left(\frac{dR}{R} \right)$. Thus, the relative change in F is about
 4 times the relative change in R . So a 5% increase in the radius corresponds to a 20% increase in blood flow.

45. (a) $dc = \frac{dc}{dx} dx = 0 dx = 0$

(b) $d(cu) = \frac{d}{dx}(cu) dx = c \frac{du}{dx} dx = c du$

(c) $d(u+v) = \frac{d}{dx}(u+v) dx = \left(\frac{du}{dx} + \frac{dv}{dx} \right) dx = \frac{du}{dx} dx + \frac{dv}{dx} dx = du + dv$

(d) $d(uv) = \frac{d}{dx}(uv) dx = \left(u \frac{dv}{dx} + v \frac{du}{dx} \right) dx = u \frac{dv}{dx} dx + v \frac{du}{dx} dx = u dv + v du$

(e) $d\left(\frac{u}{v}\right) = \frac{d}{dx}\left(\frac{u}{v}\right) dx = \frac{v \frac{du}{dx} - u \frac{dv}{dx}}{v^2} dx = \frac{v \frac{du}{dx} dx - u \frac{dv}{dx} dx}{v^2} = \frac{v du - u dv}{v^2}$

(f) $d(x^n) = \frac{d}{dx}(x^n) dx = nx^{n-1} dx$

46. (a) $f(x) = \sin x \Rightarrow f'(x) = \cos x$, so $f(0) = 0$ and $f'(0) = 1$.

Thus, $f(x) \approx f(0) + f'(0)(x-0) = 0 + 1(x-0) = x$.

(b)

We want to know the values of x for which $y = x$ approximates $y = \sin x$ with less than a 2% difference; that is, the values of x for which

$$\left| \frac{x - \sin x}{\sin x} \right| < 0.02 \Leftrightarrow -0.02 < \frac{x - \sin x}{\sin x} < 0.02 \Leftrightarrow$$

$$\begin{cases} -0.02 \sin x < x - \sin x < 0.02 \sin x & \text{if } \sin x > 0 \\ -0.02 \sin x > x - \sin x > 0.02 \sin x & \text{if } \sin x < 0 \end{cases} \Leftrightarrow \begin{cases} 0.98 \sin x < x < 1.02 \sin x & \text{if } \sin x > 0 \\ 1.02 \sin x < x < 0.98 \sin x & \text{if } \sin x < 0 \end{cases}$$

In the first figure, we see that the graphs are very close to each other near $x = 0$. Changing the viewing rectangle and using an intersect feature (see the second figure) we find that $y = x$ intersects $y = 1.02 \sin x$ at $x \approx 0.344$. By symmetry, they also intersect at $x \approx -0.344$ (see the third figure.). Converting 0.344 radians to degrees, we get $0.344 \left(\frac{180^\circ}{\pi} \right) \approx 19.7^\circ \approx 20^\circ$, which verifies the statement.

47. (a) The graph shows that $f'(1) = 2$, so $L(x) = f(1) + f'(1)(x - 1) = 5 + 2(x - 1) = 2x + 3$.
 $f(0.9) \approx L(0.9) = 4.8$ and $f(1.1) \approx L(1.1) = 5.2$.
- (b) From the graph, we see that $f'(x)$ is positive and decreasing. This means that the slopes of the tangent lines are positive, but the tangents are becoming less steep. So the tangent lines lie *above* the curve. Thus, the estimates in part (a) are too large.
48. (a) $g'(x) = \sqrt{x^2 + 5} \Rightarrow g'(2) = \sqrt{9} = 3$. $g(1.95) \approx g(2) + g'(2)(1.95 - 2) = -4 + 3(-0.05) = -4.15$.
 $g(2.05) \approx g(2) + g'(2)(2.05 - 2) = -4 + 3(0.05) = -3.85$.
- (b) The formula $g'(x) = \sqrt{x^2 + 5}$ shows that $g'(x)$ is positive and increasing. This means that the slopes of the tangent lines are positive and the tangents are getting steeper. So the tangent lines lie *below* the graph of g . Hence, the estimates in part (a) are too small.

LABORATORY PROJECT Taylor Polynomials

1. We first write the functions described in conditions (i), (ii), and (iii):

$$\begin{aligned} P(x) &= A + Bx + Cx^2 & f(x) &= \cos x \\ P'(x) &= B + 2Cx & f'(x) &= -\sin x \\ P''(x) &= 2C & f''(x) &= -\cos x \end{aligned}$$

So, taking $a = 0$, our three conditions become

$$\begin{aligned} P(0) &= f(0): & A &= \cos 0 = 1 \\ P'(0) &= f'(0): & B &= -\sin 0 = 0 \\ P''(0) &= f''(0): & 2C &= -\cos 0 = -1 \Rightarrow C = -\frac{1}{2} \end{aligned}$$

The desired quadratic function is $P(x) = 1 - \frac{1}{2}x^2$, so the quadratic approximation is $\cos x \approx 1 - \frac{1}{2}x^2$.

The figure shows a graph of the cosine function together with its linear approximation $L(x) = 1$ and quadratic approximation $P(x) = 1 - \frac{1}{2}x^2$ near 0. You can see that the quadratic approximation is much better than the linear one.

2. Accuracy to within 0.1 means that $|\cos x - (1 - \frac{1}{2}x^2)| < 0.1 \Leftrightarrow$
 $-0.1 < \cos x - (1 - \frac{1}{2}x^2) < 0.1 \Leftrightarrow 0.1 > (1 - \frac{1}{2}x^2) - \cos x > -0.1 \Leftrightarrow$
 $\cos x + 0.1 > 1 - \frac{1}{2}x^2 > \cos x - 0.1 \Leftrightarrow \cos x - 0.1 < 1 - \frac{1}{2}x^2 < \cos x + 0.1$.

From the figure we see that this is true between A and B. Zooming in or using an intersect feature, we find that the x -coordinates of B and A are about ± 1.26 . Thus, the approximation $\cos x \approx 1 - \frac{1}{2}x^2$ is accurate to within 0.1 when $-1.26 < x < 1.26$.

3. If $P(x) = A + B(x - a) + C(x - a)^2$, then $P'(x) = B + 2C(x - a)$ and $P''(x) = 2C$. Applying the conditions (i), (ii), and (iii), we get

$$P(a) = f(a) : \quad A = f(a)$$

$$P'(a) = f'(a) : \quad B = f'(a)$$

$$P''(a) = f''(a) : \quad 2C = f''(a) \Rightarrow C = \frac{1}{2}f''(a)$$

Thus, $P(x) = A + B(x - a) + C(x - a)^2$ can be written in the form

$$P(x) = f(a) + f'(a)(x - a) + \frac{1}{2}f''(a)(x - a)^2.$$

4. From Example 2 in Section 3.10, we have $f(1) = 2$, $f'(1) = \frac{1}{4}$, and

$$f'(x) = \frac{1}{2}(x + 3)^{-1/2}. \text{ So } f''(x) = -\frac{1}{4}(x + 3)^{-3/2} \Rightarrow$$

$f''(1) = -\frac{1}{32}$. From Problem 3, the quadratic approximation $P(x)$ is

$$\begin{aligned} \sqrt{x+3} &\approx f(1) + f'(1)(x-1) + \frac{1}{2}f''(1)(x-1)^2 \\ &= 2 + \frac{1}{4}(x-1) - \frac{1}{64}(x-1)^2 \end{aligned}$$

The figure shows the function $f(x) = \sqrt{x+3}$ together with its linear approximation $L(x) = \frac{1}{4}x + \frac{7}{4}$ and its quadratic approximation $P(x)$. You can see that $P(x)$ is a better approximation than $L(x)$ and this is borne out by the numerical values in the following chart.

	from $L(x)$	actual value	from $P(x)$
$\sqrt{3.98}$	1.9950	1.99499373...	1.99499375
$\sqrt{4.05}$	2.0125	2.01246118...	2.01246094
$\sqrt{4.2}$	2.0500	2.04939015...	2.04937500

5. $T_n(x) = c_0 + c_1(x - a) + c_2(x - a)^2 + c_3(x - a)^3 + \cdots + c_n(x - a)^n$. If we put $x = a$ in this equation, then all terms after the first are 0 and we get $T_n(a) = c_0$. Now we differentiate $T_n(x)$ and obtain

$$T'_n(x) = c_1 + 2c_2(x - a) + 3c_3(x - a)^2 + 4c_4(x - a)^3 + \cdots + nc_n(x - a)^{n-1}. \text{ Substituting } x = a \text{ gives}$$

$$T'_n(a) = c_1. \text{ Differentiating again, we have}$$

$$T''_n(x) = 2c_2 + 2 \cdot 3c_3(x - a) + 3 \cdot 4c_4(x - a)^2 + \cdots + (n-1)nc_n(x - a)^{n-2} \text{ and so } T''_n(a) = 2c_2. \text{ Continuing in this manner, we get}$$

$$T'''_n(x) = 2 \cdot 3c_3 + 2 \cdot 3 \cdot 4c_4(x - a) + \cdots + (n-2)(n-1)nc_n(x - a)^{n-3} \text{ and } T'''_n(a) = 2 \cdot 3c_3.$$

By now we see the pattern. If we continue to differentiate and substitute $x = a$, we obtain $T_n^{(4)}(a) = 2 \cdot 3 \cdot 4c_4$ and in general, for any integer k between 1 and n ,

$$T_n^{(k)}(a) = 2 \cdot 3 \cdot 4 \cdot 5 \cdots k c_k = k! c_k \Rightarrow c_k = \frac{T_n^{(k)}(a)}{k!}$$

Because we want T_n and f to have the same derivatives at a , we require that $c_k = \frac{f^{(k)}(a)}{k!}$ for $k = 1, 2, \dots, n$.

6. $T_n(x) = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \cdots + \frac{f^{(n)}(a)}{n!}(x-a)^n$. To compute the coefficients in this equation we need to calculate the derivatives of f at 0:

$$\begin{array}{ll} f(x) = \cos x & f(0) = \cos 0 = 1 \\ f'(x) = -\sin x & f'(0) = -\sin 0 = 0 \\ f''(x) = -\cos x & f''(0) = -1 \\ f'''(x) = \sin x & f'''(0) = 0 \\ f^{(4)}(x) = \cos x & f^{(4)}(0) = 1 \end{array}$$

We see that the derivatives repeat in a cycle of length 4, so $f^{(5)}(0) = 0$, $f^{(6)}(0) = -1$, $f^{(7)}(0) = 0$, and $f^{(8)}(0) = 1$. From the original expression for $T_n(x)$, with $n = 8$ and $a = 0$, we have

$$\begin{aligned} T_8(x) &= f(0) + f'(0)(x-0) + \frac{f''(0)}{2!}(x-0)^2 + \frac{f'''(0)}{3!}(x-0)^3 + \cdots + \frac{f^{(8)}(0)}{8!}(x-0)^8 \\ &= 1 + 0 \cdot x + \frac{-1}{2!}x^2 + 0 \cdot x^3 + \frac{1}{4!}x^4 + 0 \cdot x^5 + \frac{-1}{6!}x^6 + 0 \cdot x^7 + \frac{1}{8!}x^8 \\ &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \frac{x^8}{8!} \end{aligned}$$

and the desired approximation is $\cos x \approx 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \frac{x^8}{8!}$. The Taylor polynomials T_2 , T_4 , and T_6

consist of the initial terms of T_8 up through degree 2, 4, and 6, respectively. Therefore, $T_2(x) = 1 - \frac{x^2}{2!}$,

$$T_4(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!}, \text{ and } T_6(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!}.$$

We graph T_2 , T_4 , T_6 , T_8 , and f :

Notice that $T_2(x)$ is a good approximation to $\cos x$ near 0, $T_4(x)$ is a good approximation on a larger interval, $T_6(x)$ is a better approximation, and $T_8(x)$ is better still. Each successive Taylor polynomial is a good approximation on a larger interval than the previous one.

3 Review

CONCEPT CHECK

- See Definition 3.1.2 and the subsequent discussions on the interpretations of the derivative as the slope of a tangent and as a rate of change.
- A function f is differentiable at a number a if its derivative f' exists at $x = a$; that is, if $f'(a)$ exists.
 - See Theorem 3.2.4. This theorem also tells us that if f is *not* continuous at a , then f is *not* differentiable at a .
- The Power Rule: If n is any real number, then $\frac{d}{dx}(x^n) = nx^{n-1}$. The derivative of a variable base raised to a constant power is the power times the base raised to the power minus one.
 - The Constant Multiple Rule: If c is a constant and f is a differentiable function, then $\frac{d}{dx}[cf(x)] = c \frac{d}{dx}f(x)$.
The derivative of a constant times a function is the constant times the derivative of the function.
 - The Sum Rule: If f and g are both differentiable, then $\frac{d}{dx}[f(x) + g(x)] = \frac{d}{dx}f(x) + \frac{d}{dx}g(x)$. The derivative of a sum of functions is the sum of the derivatives.
 - The Difference Rule: If f and g are both differentiable, then $\frac{d}{dx}[f(x) - g(x)] = \frac{d}{dx}f(x) - \frac{d}{dx}g(x)$. The derivative of a difference of functions is the difference of the derivatives.
 - The Product Rule: If f and g are both differentiable, then $\frac{d}{dx}[f(x)g(x)] = f(x) \frac{d}{dx}g(x) + g(x) \frac{d}{dx}f(x)$.
The derivative of a product of two functions is the first function times the derivative of the second function plus the second function times the derivative of the first function.
 - The Quotient Rule: If f and g are both differentiable, then $\frac{d}{dx}\left[\frac{f(x)}{g(x)}\right] = \frac{g(x) \frac{d}{dx}f(x) - f(x) \frac{d}{dx}g(x)}{[g(x)]^2}$.
The derivative of a quotient of functions is the denominator times the derivative of the numerator minus the numerator times the derivative of the denominator, all divided by the square of the denominator.
 - The Chain Rule: If f and g are both differentiable and $F = f \circ g$ is the composite function defined by $F(x) = f(g(x))$, then F is differentiable and F' is given by the product $F'(x) = f'(g(x))g'(x)$. The derivative of a composite function is the derivative of the outer function evaluated at the inner function times the derivative of the inner function.
- $y = x^n \Rightarrow y' = nx^{n-1}$
 - $y = \sin x \Rightarrow y' = \cos x$
 - $y = \cos x \Rightarrow y' = -\sin x$
 - $y = \tan x \Rightarrow y' = \sec^2 x$
 - $y = \csc x \Rightarrow y' = -\csc x \cot x$
 - $y = \sec x \Rightarrow y' = \sec x \tan x$
 - $y = \cot x \Rightarrow y' = -\csc^2 x$
- Implicit differentiation consists of differentiating both sides of an equation involving x and y with respect to x , and then solving the resulting equation for y' .
- The second derivative of a function f is the rate of change of the first derivative f' . The third derivative is the derivative (rate of change) of the second derivative. If f is the position function of an object, f' is its velocity function, f'' is its acceleration function, and f''' is its jerk function.
- The linearization L of f at $x = a$ is $L(x) = f(a) + f'(a)(x - a)$.
 - If $y = f(x)$, then the differential dy is given by $dy = f'(x) dx$.
 - See Figure 6 in Section 3.10.

TRUE-FALSE QUIZ

1. False. See the warning after Theorem 3.2.4.
2. True. This is the Sum Rule.
3. False. See the warning before the Product Rule.
4. True. This is the Chain Rule.
5. True by the Chain Rule.
6. False. $\frac{d}{dx} f(\sqrt{x}) = \frac{f'(\sqrt{x})}{2\sqrt{x}}$ by the Chain Rule.
7. False. $f(x) = |x^2 + x| = x^2 + x$ for $x \geq 0$ or $x \leq -1$ and $|x^2 + x| = -(x^2 + x)$ for $-1 < x < 0$. So $f'(x) = 2x + 1$ for $x > 0$ or $x < -1$ and $f'(x) = -(2x + 1)$ for $-1 < x < 0$. But $|2x + 1| = 2x + 1$ for $x \geq -\frac{1}{2}$ and $|2x + 1| = -2x - 1$ for $x < -\frac{1}{2}$.
8. True. $f'(r)$ exists $\Rightarrow f$ is differentiable at $r \Rightarrow f$ is continuous at $r \Rightarrow \lim_{x \rightarrow r} f(x) = f(r)$.
9. True. $g(x) = x^5 \Rightarrow g'(x) = 5x^4 \Rightarrow g'(2) = 5(2)^4 = 80$, and by the definition of the derivative,

$$\lim_{x \rightarrow 2} \frac{g(x) - g(2)}{x - 2} = g'(2) = 80.$$
10. False. $\frac{d^2 y}{dx^2}$ is the second derivative while $\left(\frac{dy}{dx}\right)^2$ is the first derivative squared. For example, if $y = x$, then

$$\frac{d^2 y}{dx^2} = 0, \text{ but } \left(\frac{dy}{dx}\right)^2 = 1.$$
11. False. A tangent line to the parabola $y = x^2$ has slope $dy/dx = 2x$, so at $(-2, 4)$ the slope of the tangent is $2(-2) = -4$ and an equation of the tangent line is $y - 4 = -4(x + 2)$. [The given equation, $y - 4 = 2x(x + 2)$, is not even linear!]
12. True. $\frac{d}{dx} (\tan^2 x) = 2 \tan x \sec^2 x$, and $\frac{d}{dx} (\sec^2 x) = 2 \sec x (\sec x \tan x) = 2 \tan x \sec^2 x$.

EXERCISES

1. Estimating the slopes of the tangent lines at $x = 2, 3$, and 5 , we obtain approximate values $0.4, 2$, and 0.1 . The slope of the tangent line at $x = 7$ is negative, so $f'(7) < 0$. Arranging the numbers in increasing order, we have:

$$f'(7) < 0 < f'(5) < f'(2) < 1 < f'(3).$$
2. $2^6 = 64$, so $f(x) = x^6$ and $a = 2$.
3. (a) $f'(r)$ is the rate at which the total cost changes with respect to the interest rate. Its units are dollars/(percent per year).
 (b) The total cost of paying off the loan is increasing by $\$1200/(\text{percent per year})$ as the interest rate reaches 10% . So if the interest rate goes up from 10% to 11% , the cost goes up approximately $\$1200$.
 (c) As r increases, C increases. So $f'(r)$ will always be positive.

For Exercises 4–6, see the hints before Exercise 5 in Section 3.2.

4.

5.

6.

7. The graph of a has tangent lines with positive slope for $x < 0$ and negative slope for $x > 0$, and the values of c fit this pattern, so c must be the graph of the derivative of the function for a . The graph of c has horizontal tangent lines to the left and right of the x -axis and b has zeros at these points. Hence, b is the graph of the derivative of the function for c . Therefore, a is the graph of f , c is the graph of f' , and b is the graph of f'' .

8. (a) Drawing slope triangles, we obtain the following estimates: $F'(1950) \approx \frac{1.1}{10} = 0.11$,

$$F'(1965) \approx \frac{-1.6}{10} = -0.16, \text{ and } F'(1987) \approx \frac{0.2}{10} = 0.02.$$

- (b) The rate of change of the average number of children born to each woman was increasing by 0.11 in 1950, decreasing by 0.16 in 1965, and increasing by 0.02 in 1987.

- (c) There are many possible reasons:

- In the baby-boom era (post-WWII), there was optimism about the economy and family size was rising.
- In the baby-bust era, there was less economic optimism, and it was considered less socially responsible to have a large family.
- In the baby-boomlet era, there was increased economic optimism and a return to more conservative attitudes.

9. $B'(1990)$ is the rate at which the total value of U.S. banknotes in circulation is changing in billions of dollars per year. To estimate the value of $B'(1990)$, we will average the difference quotients obtained using the times $t = 1985$

$$\text{and } t = 1995. \text{ Let } A = \frac{B(1985) - B(1990)}{1985 - 1990} = \frac{182.0 - 268.2}{-5} = 17.24 \text{ and}$$

$$C = \frac{B(1995) - B(1990)}{1995 - 1990} = \frac{401.5 - 268.2}{5} = 26.66. \text{ Then}$$

$$B'(1990) = \lim_{t \rightarrow 1990} \frac{B(t) - B(1990)}{t - 1990} \approx \frac{A + C}{2} = \frac{17.24 + 26.66}{2} = 21.95 \text{ billions of dollars/year.}$$

10. $f(x) = \frac{4-x}{3+x} \Rightarrow$

$$\begin{aligned} f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{\frac{4-(x+h)}{3+(x+h)} - \frac{4-x}{3+x}}{h} \\ &= \lim_{h \rightarrow 0} \frac{(4-x-h)(3+x) - (4-x)(3+x+h)}{h(3+x+h)(3+x)} = \lim_{h \rightarrow 0} \frac{-7h}{h(3+x+h)(3+x)} \\ &= \lim_{h \rightarrow 0} \frac{-7}{(3+x+h)(3+x)} = -\frac{7}{(3+x)^2} \end{aligned}$$

11. $f(x) = x^3 + 5x + 4 \Rightarrow$

$$\begin{aligned} f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{(x+h)^3 + 5(x+h) + 4 - (x^3 + 5x + 4)}{h} \\ &= \lim_{h \rightarrow 0} \frac{3x^2h + 3xh^2 + h^3 + 5h}{h} = \lim_{h \rightarrow 0} (3x^2 + 3xh + h^2 + 5) = 3x^2 + 5 \end{aligned}$$

12. (a) $f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{\sqrt{3-5(x+h)} - \sqrt{3-5x}}{h} \cdot \frac{\sqrt{3-5(x+h)} + \sqrt{3-5x}}{\sqrt{3-5(x+h)} + \sqrt{3-5x}}$

$$= \lim_{h \rightarrow 0} \frac{[3-5(x+h)] - (3-5x)}{h(\sqrt{3-5(x+h)} + \sqrt{3-5x})} = \lim_{h \rightarrow 0} \frac{-5}{\sqrt{3-5(x+h)} + \sqrt{3-5x}} = \frac{-5}{2\sqrt{3-5x}}$$

(b) Domain of f : (the radicand must be nonnegative) $3-5x \geq 0 \Rightarrow 5x \leq 3 \Rightarrow x \in (-\infty, \frac{3}{5}]$

Domain of f' : exclude $\frac{3}{5}$ because it makes the denominator zero; $x \in (-\infty, \frac{3}{5})$

(c) Our answer to part (a) is reasonable because $f'(x)$ is always negative and f is always decreasing.

13. $y = (x^4 - 3x^2 + 5)^3 \Rightarrow$

$$y' = 3(x^4 - 3x^2 + 5)^2 \cdot \frac{d}{dx}(x^4 - 3x^2 + 5) = 3(x^4 - 3x^2 + 5)^2(4x^3 - 6x) = 6x(x^4 - 3x^2 + 5)^2(2x^2 - 3)$$

14. $y = \cos(\tan x) \Rightarrow y' = -\sin(\tan x) \cdot \frac{d}{dx}(\tan x) = -\sin(\tan x)(\sec^2 x)$

15. $y = \sqrt{x} + \frac{1}{\sqrt[3]{x^4}} = x^{1/2} + x^{-4/3} \Rightarrow y' = \frac{1}{2}x^{-1/2} - \frac{4}{3}x^{-7/3} = \frac{1}{2\sqrt{x}} - \frac{4}{3\sqrt[3]{x^7}}$

16. $y = \frac{3x-2}{\sqrt{2x+1}} \Rightarrow$

$$y' = \frac{\sqrt{2x+1}(3) - (3x-2)\frac{1}{2}(2x+1)^{-1/2}(2)}{(\sqrt{2x+1})^2} \cdot \frac{(2x+1)^{1/2}}{(2x+1)^{1/2}} = \frac{3(2x+1) - (3x-2)}{(2x+1)^{3/2}} = \frac{3x+5}{(2x+1)^{3/2}}$$

17. $y = 2x\sqrt{x^2+1} \Rightarrow$

$$y' = 2x \cdot \frac{1}{2}(x^2+1)^{-1/2}(2x) + \sqrt{x^2+1}(2) = \frac{2x^2}{\sqrt{x^2+1}} + 2\sqrt{x^2+1} = \frac{2x^2 + 2(x^2+1)}{\sqrt{x^2+1}} = \frac{2(2x^2+1)}{\sqrt{x^2+1}}$$

$$18. y = (x + 1/x^2)^{\sqrt{7}} \Rightarrow y' = \sqrt{7}(x + 1/x^2)^{\sqrt{7}-1}(1 - 2/x^3)$$

$$19. y = \frac{t}{1-t^2} \Rightarrow y' = \frac{(1-t^2)(1) - t(-2t)}{(1-t^2)^2} = \frac{1-t^2+2t^2}{(1-t^2)^2} = \frac{t^2+1}{(1-t^2)^2}$$

$$20. y = \sin(\cos x) \Rightarrow y' = \cos(\cos x)(-\sin x) = -\sin x \cos(\cos x)$$

$$21. y = \tan \sqrt{1-x} \Rightarrow y' = (\sec^2 \sqrt{1-x}) \left(\frac{1}{2\sqrt{1-x}} \right) (-1) = -\frac{\sec^2 \sqrt{1-x}}{2\sqrt{1-x}}$$

$$22. \text{Using the Reciprocal Rule, } g(x) = \frac{1}{f(x)} \Rightarrow g'(x) = -\frac{f'(x)}{[f(x)]^2}, \text{ we have } y = \frac{1}{\sin(x - \sin x)} \Rightarrow$$

$$y' = -\frac{\cos(x - \sin x)(1 - \cos x)}{\sin^2(x - \sin x)}.$$

$$23. \frac{d}{dx}(xy^4 + x^2y) = \frac{d}{dx}(x + 3y) \Rightarrow x \cdot 4y^3y' + y^4 \cdot 1 + x^2 \cdot y' + y \cdot 2x = 1 + 3y' \Rightarrow$$

$$y'(4xy^3 + x^2 - 3) = 1 - y^4 - 2xy \Rightarrow y' = \frac{1 - y^4 - 2xy}{4xy^3 + x^2 - 3}$$

$$24. y = \sec(1 + x^2) \Rightarrow y' = 2x \sec(1 + x^2) \tan(1 + x^2)$$

$$25. y = \frac{\sec 2\theta}{1 + \tan 2\theta} \Rightarrow$$

$$y' = \frac{(1 + \tan 2\theta)(\sec 2\theta \tan 2\theta \cdot 2) - (\sec 2\theta)(\sec^2 2\theta \cdot 2)}{(1 + \tan 2\theta)^2} = \frac{2 \sec 2\theta [(1 + \tan 2\theta) \tan 2\theta - \sec^2 2\theta]}{(1 + \tan 2\theta)^2}$$

$$= \frac{2 \sec 2\theta (\tan 2\theta + \tan^2 2\theta - \sec^2 2\theta)}{(1 + \tan 2\theta)^2} = \frac{2 \sec 2\theta (\tan 2\theta - 1)}{(1 + \tan 2\theta)^2} \quad [1 + \tan^2 x = \sec^2 x]$$

$$26. \frac{d}{dx}(x^2 \cos y + \sin 2y) = \frac{d}{dx}(xy) \Rightarrow x^2(-\sin y \cdot y') + (\cos y)(2x) + \cos 2y \cdot 2y' = x \cdot y' + y \cdot 1 \Rightarrow$$

$$y'(-x^2 \sin y + 2 \cos 2y - x) = y - 2x \cos y \Rightarrow y' = \frac{y - 2x \cos y}{2 \cos 2y - x^2 \sin y - x}$$

$$27. y = (1 - x^{-1})^{-1} \Rightarrow$$

$$y' = -1(1 - x^{-1})^{-2}[-(-1x^{-2})] = -(1 - 1/x)^{-2}x^{-2} = -((x-1)/x)^{-2}x^{-2} = -(x-1)^{-2}$$

$$28. y = (x + \sqrt{x})^{-1/3} \Rightarrow y' = -\frac{1}{3}(x + \sqrt{x})^{-4/3} \left(1 + \frac{1}{2\sqrt{x}} \right)$$

$$29. \sin(xy) = x^2 - y \Rightarrow \cos(xy)(xy' + y \cdot 1) = 2x - y' \Rightarrow x \cos(xy)y' + y' = 2x - y \cos(xy) \Rightarrow$$

$$y'[x \cos(xy) + 1] = 2x - y \cos(xy) \Rightarrow y' = \frac{2x - y \cos(xy)}{x \cos(xy) + 1}$$

$$30. y = \sqrt{\sin \sqrt{x}} \Rightarrow y' = \frac{1}{2}(\sin \sqrt{x})^{-1/2}(\cos \sqrt{x}) \left(\frac{1}{2\sqrt{x}} \right) = \frac{\cos \sqrt{x}}{4\sqrt{x} \sin \sqrt{x}}$$

$$31. y = \cot(3x^2 + 5) \Rightarrow y' = -\csc^2(3x^2 + 5)(6x) = -6x \csc^2(3x^2 + 5)$$

$$32. y = \frac{(x + \lambda)^4}{x^4 + \lambda^4} \Rightarrow y' = \frac{(x^4 + \lambda^4)(4)(x + \lambda)^3 - (x + \lambda)^4(4x^3)}{(x^4 + \lambda^4)^2} = \frac{4(x + \lambda)^3(\lambda^4 - \lambda x^3)}{(x^4 + \lambda^4)^2}$$

$$33. y = \sin(\tan \sqrt{1 + x^3}) \Rightarrow y' = \cos(\tan \sqrt{1 + x^3})(\sec^2 \sqrt{1 + x^3})[3x^2/(2\sqrt{1 + x^3})]$$

$$34. y = (\sin mx)/x \Rightarrow y' = (mx \cos mx - \sin mx)/x^2$$

$$35. y = \tan^2(\sin \theta) = [\tan(\sin \theta)]^2 \Rightarrow y' = 2[\tan(\sin \theta)] \cdot \sec^2(\sin \theta) \cdot \cos \theta$$

$$36. x \tan y = y - 1 \Rightarrow \tan y + (x \sec^2 y) y' = y' \Rightarrow y' = \frac{\tan y}{1 - x \sec^2 y}$$

$$37. y = (x \tan x)^{1/5} \Rightarrow y' = \frac{1}{5}(x \tan x)^{-4/5}(\tan x + x \sec^2 x)$$

$$38. y = \frac{(x-1)(x-4)}{(x-2)(x-3)} = \frac{x^2 - 5x + 4}{x^2 - 5x + 6} \Rightarrow$$

$$y' = \frac{(x^2 - 5x + 6)(2x - 5) - (x^2 - 5x + 4)(2x - 5)}{(x^2 - 5x + 6)^2} = \frac{2(2x - 5)}{(x - 2)^2(x - 3)^2}$$

$$39. f(t) = \sqrt{4t+1} \Rightarrow f'(t) = \frac{1}{2}(4t+1)^{-1/2} \cdot 4 = 2(4t+1)^{-1/2} \Rightarrow$$

$$f''(t) = 2(-\frac{1}{2})(4t+1)^{-3/2} \cdot 4 = -4/(4t+1)^{3/2}, \text{ so } f''(2) = -4/9^{3/2} = -\frac{4}{27}.$$

$$40. g(\theta) = \theta \sin \theta \Rightarrow g'(\theta) = \theta \cos \theta + \sin \theta \cdot 1 \Rightarrow g''(\theta) = \theta(-\sin \theta) + \cos \theta \cdot 1 + \cos \theta = 2 \cos \theta - \theta \sin \theta,$$

$$\text{so } g''(\pi/6) = 2 \cos(\pi/6) - (\pi/6) \sin(\pi/6) = 2(\sqrt{3}/2) - (\pi/6)(1/2) = \sqrt{3} - \pi/12.$$

$$41. x^6 + y^6 = 1 \Rightarrow 6x^5 + 6y^5 y' = 0 \Rightarrow y' = -x^5/y^5 \Rightarrow$$

$$y'' = -\frac{y^5(5x^4) - x^5(5y^4 y')}{(y^5)^2} = -\frac{5x^4 y^4 [y - x(-x^5/y^5)]}{y^{10}} = -\frac{5x^4 [(y^6 + x^6)/y^5]}{y^6} = -\frac{5x^4}{y^{11}}$$

$$42. f(x) = (2-x)^{-1} \Rightarrow f'(x) = (2-x)^{-2} \Rightarrow f''(x) = 2(2-x)^{-3} \Rightarrow f'''(x) = 2 \cdot 3(2-x)^{-4} \Rightarrow$$

$$f^{(4)}(x) = 2 \cdot 3 \cdot 4(2-x)^{-5}. \text{ In general, } f^{(n)}(x) = 2 \cdot 3 \cdot 4 \cdots n(2-x)^{-(n+1)} = \frac{n!}{(2-x)^{(n+1)}}.$$

$$43. \lim_{x \rightarrow 0} \frac{\sec x}{1 - \sin x} = \frac{\sec 0}{1 - \sin 0} = \frac{1}{1 - 0} = 1$$

$$44. \lim_{t \rightarrow 0} \frac{t^3}{\tan^3 2t} = \lim_{t \rightarrow 0} \frac{t^3 \cos^3 2t}{\sin^3 2t} = \lim_{t \rightarrow 0} \cos^3 2t \cdot \frac{1}{8 \frac{\sin^3 2t}{(2t)^3}} = \lim_{t \rightarrow 0} \frac{\cos^3 2t}{8 \left(\lim_{t \rightarrow 0} \frac{\sin 2t}{2t} \right)^3} = \frac{1}{8 \cdot 1^3} = \frac{1}{8}$$

$$45. y = 4 \sin^2 x \Rightarrow y' = 4 \cdot 2 \sin x \cos x. \text{ At } (\frac{\pi}{6}, 1), y' = 8 \cdot \frac{1}{2} \cdot \frac{\sqrt{3}}{2} = 2\sqrt{3}, \text{ so an equation of the tangent line is}$$

$$y - 1 = 2\sqrt{3}(x - \frac{\pi}{6}), \text{ or } y = 2\sqrt{3}x + 1 - \pi\sqrt{3}/3.$$

$$46. y = \frac{x^2 - 1}{x^2 + 1} \Rightarrow y' = \frac{(x^2 + 1)(2x) - (x^2 - 1)(2x)}{(x^2 + 1)^2} = \frac{4x}{(x^2 + 1)^2}. \text{ At } (0, -1), y' = 0, \text{ so an equation of the}$$

$$\text{tangent line is } y + 1 = 0(x - 0), \text{ or } y = -1.$$

$$47. y = \sqrt{1 + 4 \sin x} \Rightarrow y' = \frac{1}{2}(1 + 4 \sin x)^{-1/2} \cdot 4 \cos x = \frac{2 \cos x}{\sqrt{1 + 4 \sin x}}. \text{ At } (0, 1), y' = \frac{2}{\sqrt{1}} = 2, \text{ so an}$$

$$\text{equation of the tangent line is } y - 1 = 2(x - 0), \text{ or } y = 2x + 1.$$

$$48. x^2 + 4xy + y^2 = 13 \Rightarrow 2x + 4(xy' + y \cdot 1) + 2yy' = 0 \Rightarrow x + 2xy' + 2y + yy' = 0 \Rightarrow$$

$$2xy' + yy' = -x - 2y \Rightarrow y'(2x + y) = -x - 2y \Rightarrow y' = \frac{-x - 2y}{2x + y}. \text{ At } (2, 1), y' = \frac{-2 - 2}{4 + 1} = -\frac{4}{5}, \text{ so}$$

$$\text{an equation of the tangent line is } y - 1 = -\frac{4}{5}(x - 2), \text{ or } y = -\frac{4}{5}x + \frac{13}{5}.$$

49. (a) $f(x) = x\sqrt{5-x} \Rightarrow$

$$f'(x) = x \left[\frac{1}{2}(5-x)^{-1/2}(-1) \right] + \sqrt{5-x} = \frac{-x}{2\sqrt{5-x}} + \sqrt{5-x} \cdot \frac{2\sqrt{5-x}}{2\sqrt{5-x}}$$

$$= \frac{-x}{2\sqrt{5-x}} + \frac{2(5-x)}{2\sqrt{5-x}} = \frac{-x+10-2x}{2\sqrt{5-x}} = \frac{10-3x}{2\sqrt{5-x}}$$

(b) At $(1, 2)$: $f'(1) = \frac{7}{4}$. So an equation of the tangent line is $y - 2 = \frac{7}{4}(x - 1)$ or $y = \frac{7}{4}x + \frac{1}{4}$.

At $(4, 4)$: $f'(4) = -\frac{2}{2} = -1$. So an equation of the tangent line is $y - 4 = -1(x - 4)$ or $y = -x + 8$.

The graphs look reasonable, since f' is positive where f has tangents with positive slope, and f' is negative where f has tangents with negative slope.

50. (a) $f(x) = 4x - \tan x \Rightarrow f'(x) = 4 - \sec^2 x \Rightarrow f''(x) = -2 \sec x (\sec x \tan x) = -2 \sec^2 x \tan x$.

We can see that our answers are reasonable, since the graph of f' is 0 where f has a horizontal tangent, and the graph of f' is positive where f has tangents with positive slope and negative where f has tangents with negative slope. The same correspondence holds between the graphs of f' and f'' .

51. $y = \sin x + \cos x \Rightarrow y' = \cos x - \sin x = 0 \Leftrightarrow \cos x = \sin x$ and $0 \leq x \leq 2\pi \Leftrightarrow x = \frac{\pi}{4}$ or $\frac{5\pi}{4}$, so the points are $(\frac{\pi}{4}, \sqrt{2})$ and $(\frac{5\pi}{4}, -\sqrt{2})$.

52. $x^2 + 2y^2 = 1 \Rightarrow 2x + 4yy' = 0 \Rightarrow y' = -x/(2y) = 1 \Leftrightarrow x = -2y$. Since the points lie on the ellipse, we have $(-2y)^2 + 2y^2 = 1 \Rightarrow 6y^2 = 1 \Rightarrow y = \pm \frac{1}{\sqrt{6}}$. The points are $(-\frac{2}{\sqrt{6}}, \frac{1}{\sqrt{6}})$ and $(\frac{2}{\sqrt{6}}, -\frac{1}{\sqrt{6}})$.

53. $f(x) = (x-a)(x-b)(x-c) \Rightarrow f'(x) = (x-b)(x-c) + (x-a)(x-c) + (x-a)(x-b)$. So

$$\frac{f'(x)}{f(x)} = \frac{(x-b)(x-c) + (x-a)(x-c) + (x-a)(x-b)}{(x-a)(x-b)(x-c)} = \frac{1}{x-a} + \frac{1}{x-b} + \frac{1}{x-c}.$$

54. (a) $\cos 2x = \cos^2 x - \sin^2 x \Rightarrow -2 \sin 2x = -2 \cos x \sin x - 2 \sin x \cos x \Leftrightarrow \sin 2x = 2 \sin x \cos x$

(b) $\sin(x+a) = \sin x \cos a + \cos x \sin a \Rightarrow \cos(x+a) = \cos x \cos a - \sin x \sin a$.

55. (a) $h(x) = f(x)g(x) \Rightarrow h'(x) = f(x)g'(x) + g(x)f'(x) \Rightarrow$

$$h'(2) = f(2)g'(2) + g(2)f'(2) = (3)(4) + (5)(-2) = 12 - 10 = 2$$

(b) $F(x) = f(g(x)) \Rightarrow F'(x) = f'(g(x))g'(x) \Rightarrow F'(2) = f'(g(2))g'(2) = f'(5)(4) = 11 \cdot 4 = 44$

$$56. (a) P(x) = f(x)g(x) \Rightarrow P'(x) = f(x)g'(x) + g(x)f'(x) \Rightarrow$$

$$P'(2) = f(2)g'(2) + g(2)f'(2) = (1)\left(\frac{6-0}{3-0}\right) + (4)\left(\frac{9-3}{3-0}\right) = (1)(2) + (4)(-1) = 2 - 4 = -2$$

$$(b) Q(x) = \frac{f(x)}{g(x)} \Rightarrow Q'(x) = \frac{g(x)f'(x) - f(x)g'(x)}{[g(x)]^2} \Rightarrow$$

$$Q'(2) = \frac{g(2)f'(2) - f(2)g'(2)}{[g(2)]^2} = \frac{(4)(-1) - (1)(2)}{4^2} = \frac{-6}{16} = -\frac{3}{8}$$

$$(c) C(x) = f(g(x)) \Rightarrow C'(x) = f'(g(x))g'(x) \Rightarrow$$

$$C'(2) = f'(g(2))g'(2) = f'(4)g'(2) = \left(\frac{6-0}{5-3}\right)(2) = (3)(2) = 6$$

$$57. f(x) = x^2g(x) \Rightarrow f'(x) = x^2g'(x) + g(x)(2x) = x[xg'(x) + 2g(x)]$$

$$58. f(x) = g(x^2) \Rightarrow f'(x) = g'(x^2)(2x) = 2xg'(x^2)$$

$$59. f(x) = [g(x)]^2 \Rightarrow f'(x) = 2[g(x)]^1 \cdot g'(x) = 2g(x)g'(x)$$

$$60. f(x) = x^a g(x^b) \Rightarrow f'(x) = ax^{a-1}g(x^b) + x^a g'(x^b)(bx^{b-1}) = ax^{a-1}g(x^b) + bx^{a+b-1}g'(x^b)$$

$$61. f(x) = g(g(x)) \Rightarrow f'(x) = g'(g(x))g'(x)$$

$$62. f(x) = \sin(g(x)) \Rightarrow f'(x) = \cos(g(x)) \cdot g'(x)$$

$$63. f(x) = g(\sin x) \Rightarrow f'(x) = g'(\sin x) \cdot \cos x$$

$$64. f(x) = g(\tan \sqrt{x}) \Rightarrow$$

$$f'(x) = g'(\tan \sqrt{x}) \cdot \frac{d}{dx}(\tan \sqrt{x}) = g'(\tan \sqrt{x}) \cdot \sec^2 \sqrt{x} \cdot \frac{d}{dx}(\sqrt{x}) = \frac{g'(\tan \sqrt{x}) \sec^2 \sqrt{x}}{2\sqrt{x}}$$

$$65. h(x) = \frac{f(x)g(x)}{f(x) + g(x)} \Rightarrow$$

$$h'(x) = \frac{[f(x) + g(x)][f(x)g'(x) + g(x)f'(x)] - f(x)g(x)[f'(x) + g'(x)]}{[f(x) + g(x)]^2}$$

$$= \frac{[f(x)]^2 g'(x) + f(x)g(x)f'(x) + f(x)g(x)g'(x) + [g(x)]^2 f'(x) - f(x)g(x)f'(x) - f(x)g(x)g'(x)}{[f(x) + g(x)]^2}$$

$$= \frac{f'(x)[g(x)]^2 + g'(x)[f(x)]^2}{[f(x) + g(x)]^2}$$

$$66. h(x) = \sqrt{\frac{f(x)}{g(x)}} \Rightarrow h'(x) = \frac{f'(x)g(x) - f(x)g'(x)}{2\sqrt{f(x)/g(x)}[g(x)]^2} = \frac{f'(x)g(x) - f(x)g'(x)}{2[g(x)]^{3/2}\sqrt{f(x)}}$$

$$67. \text{ Using the Chain Rule repeatedly, } h(x) = f(g(\sin 4x)) \Rightarrow$$

$$h'(x) = f'(g(\sin 4x)) \cdot \frac{d}{dx}(g(\sin 4x)) = f'(g(\sin 4x)) \cdot g'(\sin 4x) \cdot \frac{d}{dx}(\sin 4x)$$

$$= f'(g(\sin 4x))g'(\sin 4x)(\cos 4x)(4)$$

68. (a)

 (b) The average rate of change is larger on $[2, 3]$.

 (c) The instantaneous rate of change (the slope of the tangent) is larger at $x = 2$.

 (d) $f(x) = x - 2 \sin x \Rightarrow f'(x) = 1 - 2 \cos x$, so

$$f'(2) = 1 - 2 \cos 2 \approx 1.8323 \text{ and}$$

$$f'(5) = 1 - 2 \cos 5 \approx 0.4327.$$

 So $f'(2) > f'(5)$, as predicted in part (c).

 69. f is not differentiable: at $x = -4$ because f is not continuous, at $x = -1$ because f has a corner, at $x = 2$ because f is not continuous, and at $x = 5$ because f has a vertical tangent.

 70. (a) $x = \sqrt{b^2 + c^2 t^2} \Rightarrow v(t) = x' = [1/(2\sqrt{b^2 + c^2 t^2})] 2c^2 t = c^2 t / \sqrt{b^2 + c^2 t^2} \Rightarrow$

$$a(t) = v'(t) = \frac{c^2 \sqrt{b^2 + c^2 t^2} - c^2 t (c^2 t / \sqrt{b^2 + c^2 t^2})}{b^2 + c^2 t^2} = \frac{b^2 c^2}{(b^2 + c^2 t^2)^{3/2}}$$

 (b) $v(t) > 0$ for $t > 0$, so the particle always moves in the positive direction.

 71. (a) $y = t^3 - 12t + 3 \Rightarrow v(t) = y' = 3t^2 - 12 \Rightarrow a(t) = v'(t) = 6t$

 (b) $v(t) = 3(t^2 - 4) > 0$ when $t > 2$, so it moves upward when $t > 2$ and downward when $0 \leq t < 2$.

 (c) Distance upward = $y(3) - y(2) = -6 - (-13) = 7$,

 Distance downward = $y(0) - y(2) = 3 - (-13) = 16$. Total distance = $7 + 16 = 23$.

 72. (a) $V = \frac{1}{3} \pi r^2 h \Rightarrow dV/dh = \frac{1}{3} \pi r^2$ [r constant]

 (b) $V = \frac{1}{3} \pi r^2 h \Rightarrow dV/dr = \frac{2}{3} \pi r h$ [h constant]

 73. The linear density ρ is the rate of change of mass m with respect to length x . $m = x(1 + \sqrt{x}) = x + x^{3/2} \Rightarrow \rho = dm/dx = 1 + \frac{3}{2} \sqrt{x}$, so the linear density when $x = 4$ is $1 + \frac{3}{2} \sqrt{4} = 4$ kg/m.

 74. (a) $C(x) = 920 + 2x - 0.02x^2 + 0.00007x^3 \Rightarrow C'(x) = 2 - 0.04x + 0.00021x^2$

 (b) $C'(100) = 2 - 4 + 2.1 = \$0.10/\text{unit}$. This value represents the rate at which costs are increasing as the hundredth unit is produced, and is the approximate cost of producing the 101st unit.

 (c) The cost of producing the 101st item is $C(101) - C(100) = 990.10107 - 990 = \0.10107 , slightly larger than $C'(100)$.

 75. If x = edge length, then $V = x^3 \Rightarrow dV/dt = 3x^2 dx/dt = 10 \Rightarrow dx/dt = 10/(3x^2)$ and $S = 6x^2 \Rightarrow dS/dt = (12x) dx/dt = 12x[10/(3x^2)] = 40/x$. When $x = 30$, $dS/dt = \frac{40}{30} = \frac{4}{3}$ cm²/min.

 76. Given $dV/dt = 2$, find dh/dt when $h = 5$. $V = \frac{1}{3} \pi r^2 h$ and, from similar

 triangles, $\frac{r}{h} = \frac{3}{10} \Rightarrow V = \frac{\pi}{3} \left(\frac{3h}{10}\right)^2 h = \frac{3\pi}{100} h^3$, so

$$2 = \frac{dV}{dt} = \frac{9\pi}{100} h^2 \frac{dh}{dt} \Rightarrow \frac{dh}{dt} = \frac{200}{9\pi h^2} = \frac{200}{9\pi(5)^2} = \frac{8}{9\pi} \text{ cm/s}$$

 when $h = 5$.

77. Given $dh/dt = 5$ and $dx/dt = 15$, find dz/dt . $z^2 = x^2 + h^2 \Rightarrow$

$$2z \frac{dz}{dt} = 2x \frac{dx}{dt} + 2h \frac{dh}{dt} \Rightarrow \frac{dz}{dt} = \frac{1}{z}(15x + 5h). \text{ When } t = 3,$$

$$h = 45 + 3(5) = 60 \text{ and } x = 15(3) = 45 \Rightarrow z = \sqrt{45^2 + 60^2} = 75, \text{ so}$$

$$\frac{dz}{dt} = \frac{1}{75}[15(45) + 5(60)] = 13 \text{ ft/s.}$$

78. We are given $dz/dt = 30$ ft/s. By similar triangles, $\frac{y}{z} = \frac{4}{\sqrt{241}}$

$$\Rightarrow y = \frac{4}{\sqrt{241}}z, \text{ so } \frac{dy}{dt} = \frac{4}{\sqrt{241}} \frac{dz}{dt} = \frac{120}{\sqrt{241}} \approx 7.7 \text{ ft/s.}$$

79. We are given $d\theta/dt = -0.25$ rad/h. $\tan \theta = 400/x \Rightarrow$

$$x = 400 \cot \theta \Rightarrow \frac{dx}{dt} = -400 \csc^2 \theta \frac{d\theta}{dt}. \text{ When } \theta = \frac{\pi}{6},$$

$$\frac{dx}{dt} = -400(2)^2(-0.25) = 400 \text{ ft/h.}$$

80. (a) $f(x) = \sqrt{25 - x^2} \Rightarrow$

$$f'(x) = \frac{-2x}{2\sqrt{25 - x^2}} = -x(25 - x^2)^{-1/2}. \text{ So the linear}$$

approximation to $f(x)$ near 3 is

$$f(x) \approx f(3) + f'(3)(x - 3) = 4 - \frac{3}{4}(x - 3).$$

- (c) For the required accuracy, we want $\sqrt{25 - x^2} - 0.1 < 4 - \frac{3}{4}(x - 3)$

and $4 - \frac{3}{4}(x - 3) < \sqrt{25 - x^2} + 0.1$. From the graph, it appears that

these both hold for $2.24 < x < 3.66$.

81. (a) $f(x) = \sqrt[3]{1 + 3x} = (1 + 3x)^{1/3} \Rightarrow f'(x) = (1 + 3x)^{-2/3}$, so the linearization of f at $a = 0$ is

$$L(x) = f(0) + f'(0)(x - 0) = 1^{1/3} + 1^{-2/3}x = 1 + x. \text{ Thus, } \sqrt[3]{1 + 3x} \approx 1 + x \Rightarrow$$

$$\sqrt[3]{1.03} = \sqrt[3]{1 + 3(0.01)} \approx 1 + (0.01) = 1.01.$$

- (b) The linear approximation is $\sqrt[3]{1 + 3x} \approx 1 + x$, so for the required

accuracy we want $\sqrt[3]{1 + 3x} - 0.1 < 1 + x < \sqrt[3]{1 + 3x} + 0.1$. From

the graph, it appears that this is true when $-0.23 < x < 0.40$.

82. $y = x^3 - 2x^2 + 1 \Rightarrow dy = (3x^2 - 4x) dx$. When $x = 2$ and $dx = 0.2$, $dy = [3(2)^2 - 4(2)](0.2) = 0.8$.

83. $A = x^2 + \frac{1}{2}\pi(\frac{1}{2}x)^2 = (1 + \frac{\pi}{8})x^2 \Rightarrow dA = (2 + \frac{\pi}{4})x dx$.

When $x = 60$ and $dx = 0.1$, $dA = (2 + \frac{\pi}{4})60(0.1) = 12 + \frac{3\pi}{2}$, so

the maximum error is approximately $12 + \frac{3\pi}{2} \approx 16.7 \text{ cm}^2$.

84. $\lim_{x \rightarrow 1} \frac{x^{17} - 1}{x - 1} = \left[\frac{d}{dx} x^{17} \right]_{x=1} = 17(1)^{16} = 17$

85. $\lim_{h \rightarrow 0} \frac{\sqrt[4]{16+h} - 2}{h} = \left[\frac{d}{dx} \sqrt[4]{x} \right]_{x=16} = \frac{1}{4} x^{-3/4} \Big|_{x=16} = \frac{1}{4(\sqrt[4]{16})^3} = \frac{1}{32}$

86. $\lim_{\theta \rightarrow \pi/3} \frac{\cos \theta - 0.5}{\theta - \pi/3} = \left[\frac{d}{d\theta} \cos \theta \right]_{\theta=\pi/3} = -\sin \frac{\pi}{3} = -\frac{\sqrt{3}}{2}$

87. $\lim_{x \rightarrow 0} \frac{\sqrt{1+\tan x} - \sqrt{1+\sin x}}{x^3} = \lim_{x \rightarrow 0} \frac{(\sqrt{1+\tan x} - \sqrt{1+\sin x})(\sqrt{1+\tan x} + \sqrt{1+\sin x})}{x^3(\sqrt{1+\tan x} + \sqrt{1+\sin x})}$
 $= \lim_{x \rightarrow 0} \frac{(1+\tan x) - (1+\sin x)}{x^3(\sqrt{1+\tan x} + \sqrt{1+\sin x})} = \lim_{x \rightarrow 0} \frac{\sin x(1/\cos x - 1)}{x^3(\sqrt{1+\tan x} + \sqrt{1+\sin x})} \cdot \frac{\cos x}{\cos x}$
 $= \lim_{x \rightarrow 0} \frac{\sin x(1 - \cos x)}{x^3(\sqrt{1+\tan x} + \sqrt{1+\sin x}) \cos x} \cdot \frac{1 + \cos x}{1 + \cos x}$
 $= \lim_{x \rightarrow 0} \frac{\sin x \cdot \sin^2 x}{x^3(\sqrt{1+\tan x} + \sqrt{1+\sin x}) \cos x (1 + \cos x)}$
 $= \left(\lim_{x \rightarrow 0} \frac{\sin x}{x} \right)^3 \lim_{x \rightarrow 0} \frac{1}{(\sqrt{1+\tan x} + \sqrt{1+\sin x}) \cos x (1 + \cos x)}$
 $= 1^3 \cdot \frac{1}{(\sqrt{1} + \sqrt{1}) \cdot 1 \cdot (1+1)} = \frac{1}{4}$

88. Differentiating the first given equation implicitly with respect to x and using the Chain Rule, we obtain

$f(g(x)) = x \Rightarrow f'(g(x))g'(x) = 1 \Rightarrow g'(x) = \frac{1}{f'(g(x))}$. Using the second given equation to expand the denominator of this expression gives $g'(x) = \frac{1}{1 + [f(g(x))]^2}$. But the first given equation states that $f(g(x)) = x$, so $g'(x) = \frac{1}{1 + x^2}$.

89. $\frac{d}{dx} [f(2x)] = x^2 \Rightarrow f'(2x) \cdot 2 = x^2 \Rightarrow f'(2x) = \frac{1}{2}x^2$. Let $t = 2x$. Then $f'(t) = \frac{1}{2}(\frac{1}{2}t)^2 = \frac{1}{8}t^2$, so $f'(x) = \frac{1}{8}x^2$.

90. Let (b, c) be on the curve, that is, $b^{2/3} + c^{2/3} = a^{2/3}$. Now $x^{2/3} + y^{2/3} = a^{2/3} \Rightarrow \frac{2}{3}x^{-1/3} + \frac{2}{3}y^{-1/3}\frac{dy}{dx} = 0$,

so $\frac{dy}{dx} = -\frac{y^{1/3}}{x^{1/3}} = -\left(\frac{y}{x}\right)^{1/3}$, so at (b, c) the slope of the tangent line is $-(c/b)^{1/3}$ and an equation of the tangent

line is $y - c = -(c/b)^{1/3}(x - b)$ or $y = -(c/b)^{1/3}x + (c + b^{2/3}c^{1/3})$. Setting $y = 0$, we find that the x -intercept

is $b^{1/3}c^{2/3} + b = b^{1/3}(c^{2/3} + b^{2/3})$ and setting $x = 0$ we find that the y -intercept is

$c + b^{2/3}c^{1/3} = c^{1/3}(c^{2/3} + b^{2/3})$. So the length of the tangent line between these two points is

$$\begin{aligned}\sqrt{[b^{1/3}(c^{2/3} + b^{2/3})]^2 + [c^{1/3}(c^{2/3} + b^{2/3})]^2} &= \sqrt{b^{2/3}(a^{2/3})^2 + c^{2/3}(a^{2/3})^2} \\ &= \sqrt{(b^{2/3} + c^{2/3})a^{4/3}} = \sqrt{a^{2/3}a^{4/3}} \\ &= \sqrt{a^2} = a = \text{constant}\end{aligned}$$

□ PROBLEMS PLUS

1. Let a be the x -coordinate of Q . Since the derivative of $y = 1 - x^2$ is $y' = -2x$, the slope at Q is $-2a$. But since the triangle is equilateral, $\overline{AO}/\overline{OC} = \sqrt{3}/1$, so the slope at Q is $-\sqrt{3}$. Therefore, we must have that $-2a = -\sqrt{3} \Rightarrow a = \frac{\sqrt{3}}{2}$. Thus, the point Q has coordinates $\left(\frac{\sqrt{3}}{2}, 1 - \left(\frac{\sqrt{3}}{2}\right)^2\right) = \left(\frac{\sqrt{3}}{2}, \frac{1}{4}\right)$ and by symmetry, P has coordinates $\left(-\frac{\sqrt{3}}{2}, \frac{1}{4}\right)$.

2. $y = x^3 - 3x + 4 \Rightarrow y' = 3x^2 - 3$, and $y = 3(x^2 - x) \Rightarrow y' = 6x - 3$. The slopes of the tangents of the two curves are equal when $3x^2 - 3 = 6x - 3$; that is, when $x = 0$ or 2 . At $x = 0$, both tangents have slope -3 , but the curves do not intersect. At $x = 2$, both tangents have slope 9 and the curves intersect at $(2, 6)$. So there is a common tangent line at $(2, 6)$, $y = 9x - 12$.

3. (a) Put $x = 0$ and $y = 0$ in the equation: $f(0 + 0) = f(0) + f(0) + 0^2 \cdot 0 + 0 \cdot 0^2 \Rightarrow f(0) = 2f(0)$. Subtracting $f(0)$ from each side of this equation gives $f(0) = 0$.

$$(b) f'(0) = \lim_{h \rightarrow 0} \frac{f(0+h) - f(0)}{h} = \lim_{h \rightarrow 0} \frac{[f(0) + f(h) + 0^2h + 0h^2] - f(0)}{h} \\ = \lim_{h \rightarrow 0} \frac{f(h)}{h} = \lim_{x \rightarrow 0} \frac{f(x)}{x} = 1$$

$$(c) f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{[f(x) + f(h) + x^2h + xh^2] - f(x)}{h} \\ = \lim_{h \rightarrow 0} \frac{f(h) + x^2h + xh^2}{h} = \lim_{h \rightarrow 0} \left[\frac{f(h)}{h} + x^2 + xh \right] = 1 + x^2$$

4. We find the equation of the parabola by substituting the point $(-100, 100)$, at which the car is situated, into the general equation $y = ax^2$: $100 = a(-100)^2 \Rightarrow a = \frac{1}{100}$. Now we find the equation of a tangent to the parabola at the point (x_0, y_0) . We can show that $y' = a(2x) = \frac{1}{100}(2x) = \frac{1}{50}x$, so an equation of the tangent is $y - y_0 = \frac{1}{50}x_0(x - x_0)$. Since the point (x_0, y_0) is on the parabola, we must have $y_0 = \frac{1}{100}x_0^2$, so our equation of the tangent can be simplified to $y = \frac{1}{100}x_0^2 + \frac{1}{50}x_0(x - x_0)$. We want the statue to be located on the tangent line, so we substitute its coordinates $(100, 50)$ into this equation: $50 = \frac{1}{100}x_0^2 + \frac{1}{50}x_0(100 - x_0) \Rightarrow x_0^2 - 200x_0 + 5000 = 0 \Rightarrow x_0 = \frac{1}{2} \left[200 \pm \sqrt{200^2 - 4(5000)} \right] \Rightarrow x_0 = 100 \pm 50\sqrt{2}$. But $x_0 < 100$, so the car's headlights illuminate the statue when it is located at the point $(100 - 50\sqrt{2}, 150 - 100\sqrt{2}) \approx (29.3, 8.6)$, that is, about 29.3 m east and 8.6 m north of the origin.

5. We use mathematical induction. Let S_n be the statement that $\frac{d^n}{dx^n} (\sin^4 x + \cos^4 x) = 4^{n-1} \cos(4x + n\pi/2)$.

S_1 is true because

$$\begin{aligned} \frac{d}{dx} (\sin^4 x + \cos^4 x) &= 4 \sin^3 x \cos x - 4 \cos^3 x \sin x = 4 \sin x \cos x (\sin^2 x - \cos^2 x) \\ &= -4 \sin x \cos x \cos 2x = -2 \sin 2x \cos 2x = -\sin 4x = \sin(-4x) \\ &= \cos\left(\frac{\pi}{2} - (-4x)\right) = \cos\left(\frac{\pi}{2} + 4x\right) = 4^{n-1} \cos(4x + n\frac{\pi}{2}) \quad \text{when } n = 1 \end{aligned}$$

Now assume S_k is true, that is, $\frac{d^k}{dx^k} (\sin^4 x + \cos^4 x) = 4^{k-1} \cos(4x + k\frac{\pi}{2})$. Then

$$\begin{aligned} \frac{d^{k+1}}{dx^{k+1}} (\sin^4 x + \cos^4 x) &= \frac{d}{dx} \left[\frac{d^k}{dx^k} (\sin^4 x + \cos^4 x) \right] = \frac{d}{dx} \left[4^{k-1} \cos(4x + k\frac{\pi}{2}) \right] \\ &= -4^{k-1} \sin(4x + k\frac{\pi}{2}) \cdot \frac{d}{dx} (4x + k\frac{\pi}{2}) = -4^k \sin(4x + k\frac{\pi}{2}) \\ &= 4^k \sin(-4x - k\frac{\pi}{2}) = 4^k \cos\left(\frac{\pi}{2} - (-4x - k\frac{\pi}{2})\right) \\ &= 4^k \cos(4x + (k+1)\frac{\pi}{2}) \end{aligned}$$

which shows that S_{k+1} is true.

Therefore, $\frac{d^n}{dx^n} (\sin^4 x + \cos^4 x) = 4^{n-1} \cos(4x + n\frac{\pi}{2})$ for every positive integer n , by mathematical induction.

Another proof: First write

$$\sin^4 x + \cos^4 x = (\sin^2 x + \cos^2 x)^2 - 2 \sin^2 x \cos^2 x = 1 - \frac{1}{2} \sin^2 2x = 1 - \frac{1}{4} (1 - \cos 4x) = \frac{3}{4} + \frac{1}{4} \cos 4x.$$

$$\text{Then we have } \frac{d^n}{dx^n} (\sin^4 x + \cos^4 x) = \frac{d^n}{dx^n} \left(\frac{3}{4} + \frac{1}{4} \cos 4x \right) = \frac{1}{4} \cdot 4^n \cos(4x + n\frac{\pi}{2}) = 4^{n-1} \cos(4x + n\frac{\pi}{2}).$$

6. If we divide $1 - x$ into x^n by long division, we find that $f(x) = \frac{x^n}{1-x} = -x^{n-1} - x^{n-2} - \dots - x - 1 + \frac{1}{1-x}$.

This can also be seen by multiplying the last expression by $1 - x$ and canceling terms on the right-hand side. So we

$$\text{let } g(x) = 1 + x + x^2 + \dots + x^{n-1}, \text{ so that } f(x) = \frac{1}{1-x} - g(x) \Rightarrow f^{(n)}(x) = \left(\frac{1}{1-x} \right)^{(n)} - g^{(n)}(x). \text{ But}$$

g is a polynomial of degree $(n-1)$, so its n th derivative is 0, and therefore $f^{(n)}(x) = \left(\frac{1}{1-x} \right)^{(n)}$. Now

$$\frac{d}{dx} (1-x)^{-1} = (-1)(1-x)^{-2}(-1) = (1-x)^{-2}, \quad \frac{d^2}{dx^2} (1-x)^{-1} = (-2)(1-x)^{-3}(-1) = 2(1-x)^{-3},$$

$$\frac{d^3}{dx^3} (1-x)^{-1} = (-3) \cdot 2(1-x)^{-4}(-1) = 3 \cdot 2(1-x)^{-4}, \quad \frac{d^4}{dx^4} (1-x)^{-1} = 4 \cdot 3 \cdot 2(1-x)^{-5}, \text{ and so on. So}$$

$$\text{after } n \text{ differentiations, we will have } f^{(n)}(x) = \left(\frac{1}{1-x} \right)^{(n)} = \frac{n!}{(1-x)^{n+1}}.$$

7. We must find a value x_0 such that the normal lines to the parabola $y = x^2$ at $x = \pm x_0$ intersect at a point one unit

from the points $(\pm x_0, x_0^2)$. The normals to $y = x^2$ at $x = \pm x_0$ have slopes $-\frac{1}{\pm 2x_0}$ and pass through $(\pm x_0, x_0^2)$

respectively, so the normals have the equations $y - x_0^2 = -\frac{1}{2x_0}(x - x_0)$ and $y - x_0^2 = \frac{1}{2x_0}(x + x_0)$. The

common y -intercept is $x_0^2 + \frac{1}{2}$. We want to find the value of x_0 for which the distance from $(0, x_0^2 + \frac{1}{2})$ to (x_0, x_0^2) equals 1. The square of the distance is $(x_0 - 0)^2 + [x_0^2 - (x_0^2 + \frac{1}{2})]^2 = x_0^2 + \frac{1}{4} = 1 \Leftrightarrow x_0 = \pm \frac{\sqrt{3}}{2}$. For these values of x_0 , the y -intercept is $x_0^2 + \frac{1}{2} = \frac{5}{4}$, so the center of the circle is at $(0, \frac{5}{4})$.

Another solution: Let the center of the circle be $(0, a)$. Then the equation of the circle is $x^2 + (y - a)^2 = 1$.

Solving with the equation of the parabola, $y = x^2$, we get $x^2 + (x^2 - a)^2 = 1 \Leftrightarrow x^2 + x^4 - 2ax^2 + a^2 = 1 \Leftrightarrow x^4 + (1 - 2a)x^2 + a^2 - 1 = 0$. The parabola and the circle will be tangent to each other when this quadratic equation in x^2 has equal roots; that is, when the discriminant is 0. Thus, $(1 - 2a)^2 - 4(a^2 - 1) = 0 \Leftrightarrow 1 - 4a + 4a^2 - 4a^2 + 4 = 0 \Leftrightarrow 4a = 5$, so $a = \frac{5}{4}$. The center of the circle is $(0, \frac{5}{4})$.

$$\begin{aligned} 8. \lim_{x \rightarrow a} \frac{f(x) - f(a)}{\sqrt{x} - \sqrt{a}} &= \lim_{x \rightarrow a} \left[\frac{f(x) - f(a)}{\sqrt{x} - \sqrt{a}} \cdot \frac{\sqrt{x} + \sqrt{a}}{\sqrt{x} + \sqrt{a}} \right] = \lim_{x \rightarrow a} \left[\frac{f(x) - f(a)}{x - a} \cdot (\sqrt{x} + \sqrt{a}) \right] \\ &= \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a} \cdot \lim_{x \rightarrow a} (\sqrt{x} + \sqrt{a}) = f'(a) \cdot (\sqrt{a} + \sqrt{a}) = 2\sqrt{a} f'(a) \end{aligned}$$

9. We can assume without loss of generality that $\theta = 0$ at time $t = 0$, so that $\theta = 12\pi t$ rad. [The angular velocity of the wheel is $360 \text{ rpm} = 360 \cdot (2\pi \text{ rad}) / (60 \text{ s}) = 12\pi \text{ rad/s}$.] Then the position of A as a function of time is

$$A = (40 \cos \theta, 40 \sin \theta) = (40 \cos 12\pi t, 40 \sin 12\pi t), \text{ so } \sin \alpha = \frac{y}{1.2 \text{ m}} = \frac{40 \sin \theta}{120} = \frac{\sin \theta}{3} = \frac{1}{3} \sin 12\pi t.$$

- (a) Differentiating the expression for $\sin \alpha$, we get $\cos \alpha \cdot \frac{d\alpha}{dt} = \frac{1}{3} \cdot 12\pi \cdot \cos 12\pi t = 4\pi \cos \theta$.

When $\theta = \frac{\pi}{3}$, we have $\sin \alpha = \frac{1}{3} \sin \theta = \frac{\sqrt{3}}{6}$, so $\cos \alpha = \sqrt{1 - \left(\frac{\sqrt{3}}{6}\right)^2} = \sqrt{\frac{11}{12}}$ and

$$\frac{d\alpha}{dt} = \frac{4\pi \cos \frac{\pi}{3}}{\cos \alpha} = \frac{2\pi}{\sqrt{11/12}} = \frac{4\pi\sqrt{3}}{\sqrt{11}} \approx 6.56 \text{ rad/s}.$$

- (b) By the Law of Cosines, $|AP|^2 = |OA|^2 + |OP|^2 - 2|OA||OP|\cos \theta \Rightarrow$

$$120^2 = 40^2 + |OP|^2 - 2 \cdot 40|OP|\cos \theta \Rightarrow |OP|^2 - (80 \cos \theta)|OP| - 12,800 = 0 \Rightarrow$$

$$\begin{aligned} |OP| &= \frac{1}{2} \left(80 \cos \theta \pm \sqrt{6400 \cos^2 \theta + 51,200} \right) = 40 \cos \theta \pm 40 \sqrt{\cos^2 \theta + 8} \\ &= 40 \left(\cos \theta + \sqrt{8 + \cos^2 \theta} \right) \text{ cm} \quad (\text{since } |OP| > 0) \end{aligned}$$

As a check, note that $|OP| = 160 \text{ cm}$ when $\theta = 0$ and $|OP| = 80\sqrt{2} \text{ cm}$ when $\theta = \frac{\pi}{2}$.

- (c) By part (b), the x -coordinate of P is given by $x = 40(\cos \theta + \sqrt{8 + \cos^2 \theta})$, so

$$\frac{dx}{dt} = \frac{dx}{d\theta} \frac{d\theta}{dt} = 40 \left(-\sin \theta - \frac{2 \cos \theta \sin \theta}{2\sqrt{8 + \cos^2 \theta}} \right) \cdot 12\pi = -480\pi \sin \theta \left(1 + \frac{\cos \theta}{\sqrt{8 + \cos^2 \theta}} \right) \text{ cm/s}.$$

In particular, $dx/dt = 0 \text{ cm/s}$ when $\theta = 0$ and $dx/dt = -480\pi \text{ cm/s}$ when $\theta = \frac{\pi}{2}$.

10. The equation of T_1 is $y - x_1^2 = 2x_1(x - x_1) = 2x_1x - 2x_1^2$ or

$y = 2x_1x - x_1^2$. The equation of T_2 is $y = 2x_2x - x_2^2$. Solving for the point of intersection, we get $2x(x_1 - x_2) = x_1^2 - x_2^2 \Rightarrow x = \frac{1}{2}(x_1 + x_2)$.

Therefore, the coordinates of P are $(\frac{1}{2}(x_1 + x_2), x_1x_2)$. So if the point of contact of T is (a, a^2) , then Q_1 is $(\frac{1}{2}(a + x_1), ax_1)$ and Q_2 is $(\frac{1}{2}(a + x_2), ax_2)$.

Therefore, $|PQ_1|^2 = \frac{1}{4}(a - x_2)^2 + x_1^2(a - x_2)^2 = (a - x_2)^2(\frac{1}{4} + x_1^2)$ and

$|PP_1|^2 = \frac{1}{4}(x_1 - x_2)^2 + x_1^2(x_1 - x_2)^2 = (x_1 - x_2)^2(\frac{1}{4} + x_1^2)$. So $\frac{|PQ_1|^2}{|PP_1|^2} = \frac{(a - x_2)^2}{(x_1 - x_2)^2}$, and similarly

$\frac{|PQ_2|^2}{|PP_2|^2} = \frac{(x_1 - a)^2}{(x_1 - x_2)^2}$. Finally, $\frac{|PQ_1|}{|PP_1|} + \frac{|PQ_2|}{|PP_2|} = \frac{a - x_2}{x_1 - x_2} + \frac{x_1 - a}{x_1 - x_2} = 1$.

11. It seems from the figure that as P approaches the point $(0, 2)$ from the right, $x_T \rightarrow \infty$ and $y_T \rightarrow 2^+$. As P approaches the point $(3, 0)$ from the left, it appears that $x_T \rightarrow 3^+$ and $y_T \rightarrow \infty$. So we guess that $x_T \in (3, \infty)$ and $y_T \in (2, \infty)$. It is more difficult to estimate the range of values for x_N and y_N . We might perhaps guess that $x_N \in (0, 3)$, and $y_N \in (-\infty, 0)$ or $(-2, 0)$.

In order to actually solve the problem, we implicitly differentiate the equation of the ellipse to find the equation

of the tangent line: $\frac{x^2}{9} + \frac{y^2}{4} = 1 \Rightarrow \frac{2x}{9} + \frac{2y}{4}y' = 0$, so $y' = -\frac{4}{9}\frac{x}{y}$. So at the point (x_0, y_0) on the ellipse, an

equation of the tangent line is $y - y_0 = -\frac{4}{9}\frac{x_0}{y_0}(x - x_0)$ or $4x_0x + 9y_0y = 4x_0^2 + 9y_0^2$. This can be written as

$\frac{x_0x}{9} + \frac{y_0y}{4} = \frac{x_0^2}{9} + \frac{y_0^2}{4} = 1$, because (x_0, y_0) lies on the ellipse. So an equation of the tangent line is

$$\frac{x_0x}{9} + \frac{y_0y}{4} = 1.$$

Therefore, the x -intercept x_T for the tangent line is given by $\frac{x_0x_T}{9} = 1 \Leftrightarrow x_T = \frac{9}{x_0}$, and the y -intercept y_T

is given by $\frac{y_0y_T}{4} = 1 \Leftrightarrow y_T = \frac{4}{y_0}$.

So as x_0 takes on all values in $(0, 3)$, x_T takes on all values in $(3, \infty)$, and as y_0 takes on all values in $(0, 2)$, y_T takes on all values in $(2, \infty)$. At the point (x_0, y_0) on the ellipse, the slope of the normal line is

$-\frac{1}{y'(x_0, y_0)} = \frac{9}{4}\frac{y_0}{x_0}$, and its equation is $y - y_0 = \frac{9}{4}\frac{y_0}{x_0}(x - x_0)$. So the x -intercept x_N for the normal line is

given by $0 - y_0 = \frac{9}{4}\frac{y_0}{x_0}(x_N - x_0) \Rightarrow x_N = -\frac{4x_0}{9} + x_0 = \frac{5x_0}{9}$, and the y -intercept y_N is given by

$$y_N - y_0 = \frac{9}{4}\frac{y_0}{x_0}(0 - x_0) \Rightarrow y_N = -\frac{9y_0}{4} + y_0 = -\frac{5y_0}{4}.$$

So as x_0 takes on all values in $(0, 3)$, x_N takes on all values in $(0, \frac{5}{3})$, and as y_0 takes on all values in $(0, 2)$, y_N takes on all values in $(-\frac{5}{2}, 0)$.

12. $\lim_{x \rightarrow 0} \frac{\sin(3+x)^2 - \sin 9}{x} = f'(3)$ where $f(x) = \sin x^2$. Now $f'(x) = (\cos x^2)(2x)$, so $f'(3) = 6 \cos 9$.

If the two lines L_1 and L_2 have slopes m_1 and m_2 and angles of inclination ϕ_1 and ϕ_2 , then $m_1 = \tan \phi_1$ and $m_2 = \tan \phi_2$. The triangle in the figure shows that $\phi_1 + \alpha + (180^\circ - \phi_2) = 180^\circ$ and so $\alpha = \phi_2 - \phi_1$. Therefore, using the identity for $\tan(x - y)$, we have

$$\tan \alpha = \tan(\phi_2 - \phi_1) = \frac{\tan \phi_2 - \tan \phi_1}{1 + \tan \phi_2 \tan \phi_1} \text{ and so}$$

$$\tan \alpha = \frac{m_2 - m_1}{1 + m_1 m_2}.$$

- (b) (i) The parabolas intersect when $x^2 = (x-2)^2 \Rightarrow x = 1$. If $y = x^2$, then $y' = 2x$, so the slope of the tangent to $y = x^2$ at $(1, 1)$ is $m_1 = 2(1) = 2$. If $y = (x-2)^2$, then $y' = 2(x-2)$, so the slope of the tangent to $y = (x-2)^2$ at $(1, 1)$ is $m_2 = 2(1-2) = -2$. Therefore,

$$\tan \alpha = \frac{m_2 - m_1}{1 + m_1 m_2} = \frac{-2 - 2}{1 + 2(-2)} = \frac{4}{3} \text{ and so } \alpha = \tan^{-1}\left(\frac{4}{3}\right) \approx 53^\circ \text{ (or } 127^\circ\text{)}.$$

- (ii) $x^2 - y^2 = 3$ and $x^2 - 4x + y^2 + 3 = 0$ intersect when $x^2 - 4x + (x^2 - 3) + 3 = 0 \Leftrightarrow 2x(x-2) = 0$

$$\Rightarrow x = 0 \text{ or } 2, \text{ but } 0 \text{ is extraneous. If } x = 2, \text{ then } y = \pm 1. \text{ If } x^2 - y^2 = 3 \text{ then } 2x - 2yy' = 0 \Rightarrow$$

$$y' = x/y \text{ and } x^2 - 4x + y^2 + 3 = 0 \Rightarrow 2x - 4 + 2yy' = 0 \Rightarrow y' = \frac{2-x}{y}. \text{ At } (2, 1) \text{ the slopes are}$$

$$m_1 = 2 \text{ and } m_2 = 0, \text{ so } \tan \alpha = \frac{0-2}{1+2 \cdot 0} = -2 \Rightarrow \alpha \approx 117^\circ. \text{ At } (2, -1) \text{ the slopes are } m_1 = -2 \text{ and}$$

$$m_2 = 0, \text{ so } \tan \alpha = \frac{0-(-2)}{1+(-2)(0)} = 2 \Rightarrow \alpha \approx 63^\circ \text{ (or } 117^\circ\text{)}.$$

14. $y^2 = 4px \Rightarrow 2yy' = 4p \Rightarrow y' = 2p/y \Rightarrow$ slope of tangent at $P(x_1, y_1)$ is $m_1 = 2p/y_1$. The slope of FP is $m_2 = \frac{y_1}{x_1 - p}$, so by the formula from Problem 13(a),

$$\begin{aligned} \tan \alpha &= \frac{y_1/(x_1 - p) - 2p/y_1}{1 + (2p/y_1)(y_1/(x_1 - p))} = \frac{y_1(x_1 - p) - 2p(x_1 - p)}{y_1(x_1 - p) + 2py_1} \\ &= \frac{4px_1 - 2px_1 + 2p^2}{x_1y_1 - py_1 + 2py_1} = \frac{2p(p + x_1)}{y_1(p + x_1)} = \frac{2p}{y_1} = \text{slope of tangent at } P = \tan \beta \end{aligned}$$

Since $0 \leq \alpha, \beta \leq \frac{\pi}{2}$, this proves that $\alpha = \beta$.

15. Since $\angle ROQ = \angle OQP = \theta$, the triangle QOR is isosceles, so

$$|QR| = |RO| = x. \text{ By the Law of Cosines, } x^2 = x^2 + r^2 - 2rx \cos \theta. \text{ Hence,}$$

$$2rx \cos \theta = r^2, \text{ so } x = \frac{r^2}{2r \cos \theta} = \frac{r}{2 \cos \theta}. \text{ Note that as } y \rightarrow 0^+, \theta \rightarrow 0^+ \text{ (since}$$

$$\sin \theta = y/r), \text{ and hence } x \rightarrow \frac{r}{2 \cos 0} = \frac{r}{2}. \text{ Thus, as } P \text{ is taken closer and closer}$$

to the x -axis, the point R approaches the midpoint of the radius AO .

$$16. \lim_{x \rightarrow 0} \frac{f(x)}{g(x)} = \lim_{x \rightarrow 0} \frac{f(x) - 0}{g(x) - 0} = \lim_{x \rightarrow 0} \frac{f(x) - f(0)}{g(x) - g(0)} = \lim_{x \rightarrow 0} \frac{\frac{f(x) - f(0)}{x - 0}}{\frac{g(x) - g(0)}{x - 0}} = \frac{\lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x - 0}}{\lim_{x \rightarrow 0} \frac{g(x) - g(0)}{x - 0}} = \frac{f'(0)}{g'(0)}$$

$$\begin{aligned}
 17. \lim_{x \rightarrow 0} \frac{\sin(a + 2x) - 2\sin(a + x) + \sin a}{x^2} &= \lim_{x \rightarrow 0} \frac{\sin a \cos 2x + \cos a \sin 2x - 2\sin a \cos x - 2\cos a \sin x + \sin a}{x^2} \\
 &= \lim_{x \rightarrow 0} \frac{\sin a (\cos 2x - 2\cos x + 1) + \cos a (\sin 2x - 2\sin x)}{x^2} \\
 &= \lim_{x \rightarrow 0} \frac{\sin a (2\cos^2 x - 1 - 2\cos x + 1) + \cos a (2\sin x \cos x - 2\sin x)}{x^2} \\
 &= \lim_{x \rightarrow 0} \frac{\sin a (2\cos x)(\cos x - 1) + \cos a (2\sin x)(\cos x - 1)}{x^2} \\
 &= \lim_{x \rightarrow 0} \frac{2(\cos x - 1)[\sin a \cos x + \cos a \sin x](\cos x + 1)}{x^2(\cos x + 1)} \\
 &= \lim_{x \rightarrow 0} \frac{-2\sin^2 x [\sin(a + x)]}{x^2(\cos x + 1)} = -2 \lim_{x \rightarrow 0} \left(\frac{\sin x}{x} \right)^2 \cdot \frac{\sin(a + x)}{\cos x + 1} = -2(1)^2 \frac{\sin(a + 0)}{\cos 0 + 1} = -\sin a
 \end{aligned}$$

18. Suppose that $y = mx + c$ is a tangent line to the ellipse. Then it intersects the ellipse at only one point, so the

discriminant of the equation $\frac{x^2}{a^2} + \frac{(mx + c)^2}{b^2} = 1 \Leftrightarrow (b^2 + a^2m^2)x^2 + 2mca^2x + a^2c^2 - a^2b^2 = 0$ must

be 0; that is,

$$\begin{aligned}
 0 &= (2mca^2)^2 - 4(b^2 + a^2m^2)(a^2c^2 - a^2b^2) \\
 &= 4a^4c^2m^2 - 4a^2b^2c^2 + 4a^2b^4 - 4a^4c^2m^2 + 4a^4b^2m^2 = 4a^2b^2(a^2m^2 + b^2 - c^2)
 \end{aligned}$$

Therefore, $a^2m^2 + b^2 - c^2 = 0$.

Now if a point (α, β) lies on the line $y = mx + c$, then $c = \beta - m\alpha$, so from above,

$$0 = a^2m^2 + b^2 - (\beta - m\alpha)^2 = (a^2 - \alpha^2)m^2 + 2\alpha\beta m + b^2 - \beta^2 \Leftrightarrow m^2 + \frac{2\alpha\beta}{a^2 - \alpha^2}m + \frac{b^2 - \beta^2}{a^2 - \alpha^2} = 0.$$

(a) Suppose that the two tangent lines from the point (α, β) to the ellipse have slopes m and $\frac{1}{m}$. Then m and $\frac{1}{m}$

are roots of the equation $z^2 + \frac{2\alpha\beta}{a^2 - \alpha^2}z + \frac{b^2 - \beta^2}{a^2 - \alpha^2} = 0$. This implies that $(z - m)\left(z - \frac{1}{m}\right) = 0 \Leftrightarrow$

$z^2 - \left(m + \frac{1}{m}\right)z + m\left(\frac{1}{m}\right) = 0$, so equating the constant terms in the two quadratic equations, we get

$\frac{b^2 - \beta^2}{a^2 - \alpha^2} = m\left(\frac{1}{m}\right) = 1$, and hence $b^2 - \beta^2 = a^2 - \alpha^2$. So (α, β) lies on the hyperbola $x^2 - y^2 = a^2 - b^2$.

- (b) If the two tangent lines from the point (α, β) to the ellipse have slopes m and $-\frac{1}{m}$, then m and $-\frac{1}{m}$ are roots of the quadratic equation, and so $(z - m)\left(z + \frac{1}{m}\right) = 0$, and equating the constant terms as in part (a), we get $\frac{b^2 - \beta^2}{a^2 - \alpha^2} = -1$, and hence $b^2 - \beta^2 = \alpha^2 - a^2$. So the point (α, β) lies on the circle $x^2 + y^2 = a^2 + b^2$.

19. $y = x^4 - 2x^2 - x \Rightarrow y' = 4x^3 - 4x - 1$. The equation of the tangent line at $x = a$ is $y - (a^4 - 2a^2 - a) = (4a^3 - 4a - 1)(x - a)$ or $y = (4a^3 - 4a - 1)x + (-3a^4 + 2a^2)$ and similarly for $x = b$. So if at $x = a$ and $x = b$ we have the same tangent line, then $4a^3 - 4a - 1 = 4b^3 - 4b - 1$ and $-3a^4 + 2a^2 = -3b^4 + 2b^2$. The first equation gives $a^3 - b^3 = a - b \Rightarrow (a - b)(a^2 + ab + b^2) = (a - b)$. Assuming $a \neq b$, we have $1 = a^2 + ab + b^2$. The second equation gives $3(a^4 - b^4) = 2(a^2 - b^2) \Rightarrow 3(a^2 - b^2)(a^2 + b^2) = 2(a^2 - b^2)$ which is true if $a = -b$. Substituting into $1 = a^2 + ab + b^2$ gives $1 = a^2 - a^2 + a^2 \Rightarrow a = \pm 1$ so that $a = 1$ and $b = -1$ or vice versa. Thus, the points $(1, -2)$ and $(-1, 0)$ have a common tangent line.

As long as there are only two such points, we are done. So we show that these are in fact the only two such points. Suppose that $a^2 - b^2 \neq 0$. Then $3(a^2 - b^2)(a^2 + b^2) = 2(a^2 - b^2)$ gives $3(a^2 + b^2) = 2$ or $a^2 + b^2 = \frac{2}{3}$. Thus, $ab = (a^2 + ab + b^2) - (a^2 + b^2) = 1 - \frac{2}{3} = \frac{1}{3}$, so $b = \frac{1}{3a}$. Hence, $a^2 + \frac{1}{9a^2} = \frac{2}{3}$, so $9a^4 + 1 = 6a^2 \Rightarrow 0 = 9a^4 - 6a^2 + 1 = (3a^2 - 1)^2$. So $3a^2 - 1 = 0 \Rightarrow a^2 = \frac{1}{3} \Rightarrow b^2 = \frac{1}{9a^2} = \frac{1}{3} = a^2$, contradicting our assumption that $a^2 \neq b^2$.

20. Suppose that the normal lines at the three points (a_1, a_1^2) , (a_2, a_2^2) , and (a_3, a_3^2) intersect at a common point. Now if one of the a_i is 0 (suppose $a_1 = 0$) then by symmetry $a_2 = -a_3$, so $a_1 + a_2 + a_3 = 0$. So we can assume that none of the a_i is 0.

The slope of the tangent line at (a_i, a_i^2) is $2a_i$, so the slope of the normal line is $-\frac{1}{2a_i}$ and its equation is $y - a_i^2 = -\frac{1}{2a_i}(x - a_i)$. We solve for the x -coordinate of the intersection of the normal lines from (a_1, a_1^2) and (a_2, a_2^2) : $y = a_1^2 - \frac{1}{2a_1}(x - a_1) = a_2^2 - \frac{1}{2a_2}(x - a_2) \Rightarrow$

$$x \left(\frac{1}{2a_2} - \frac{1}{2a_1} \right) = a_2^2 - a_1^2 \Rightarrow x \left(\frac{a_1 - a_2}{2a_1 a_2} \right) = (-a_1 - a_2)(a_1 + a_2) \Leftrightarrow x = -2a_1 a_2 (a_1 + a_2) \quad (*).$$

Similarly, solving for the x -coordinate of the intersections of the normal lines from (a_1, a_1^2) and (a_3, a_3^2) gives

$$x = -2a_1 a_3 (a_1 + a_3) \quad (\dagger).$$

$$\begin{aligned} \text{Equating } (*) \text{ and } (\dagger) \text{ gives } a_2(a_1 + a_2) &= a_3(a_1 + a_3) \Leftrightarrow a_1(a_2 - a_3) = a_3^2 - a_2^2 = -(a_2 + a_3)(a_2 - a_3) \\ \Leftrightarrow a_1 &= -(a_2 + a_3) \Leftrightarrow a_1 + a_2 + a_3 = 0. \end{aligned}$$

21.

Because of the periodic nature of the lattice points, it suffices to consider the points in the 5×2 grid shown. We can see that the minimum value of r occurs when there is a line with slope $\frac{2}{5}$ which touches the circle centered at $(3, 1)$ and the circles centered at $(0, 0)$ and $(5, 2)$. To find P , the point at which the line is tangent to the circle at $(0, 0)$,

$$\text{we simultaneously solve } x^2 + y^2 = r^2 \text{ and } y = -\frac{5}{2}x \Rightarrow x^2 + \frac{25}{4}x^2 = r^2 \Rightarrow x^2 = \frac{4}{29}r^2 \Rightarrow$$

$$x = \frac{2}{\sqrt{29}}r, y = -\frac{5}{\sqrt{29}}r. \text{ To find } Q, \text{ we either use symmetry or solve } (x-3)^2 + (y-1)^2 = r^2 \text{ and}$$

$$y-1 = -\frac{5}{2}(x-3). \text{ As above, we get } x = 3 - \frac{2}{\sqrt{29}}r, y = 1 + \frac{5}{\sqrt{29}}r. \text{ Now the slope of the line } PQ \text{ is } \frac{2}{5}, \text{ so}$$

$$m_{PQ} = \frac{1 + \frac{5}{\sqrt{29}}r - \left(-\frac{5}{\sqrt{29}}r\right)}{3 - \frac{2}{\sqrt{29}}r - \frac{2}{\sqrt{29}}r} = \frac{1 + \frac{10}{\sqrt{29}}r}{3 - \frac{4}{\sqrt{29}}r} = \frac{\sqrt{29} + 10r}{3\sqrt{29} - 4r} = \frac{2}{5} \Rightarrow 5\sqrt{29} + 50r = 6\sqrt{29} - 8r \Leftrightarrow$$

$$58r = \sqrt{29} \Leftrightarrow r = \frac{\sqrt{29}}{58}. \text{ So the minimum value of } r \text{ for which any line with slope } \frac{2}{5} \text{ intersects circles with radius } r \text{ centered at the lattice points on the plane is } r = \frac{\sqrt{29}}{58} \approx 0.093.$$

22.

Assume the axes of the cone and the cylinder are parallel. Let H denote the initial height of the water. When the cone has been dropping for t seconds, the water level has risen x meters, so the tip of the cone is $x + t$ meters below the water line. We want to find dx/dt when $x + t = h$ (when the cone is completely submerged). Using similar

$$\text{triangles, } \frac{r_1}{x+t} = \frac{r}{h} \Rightarrow r_1 = \frac{r}{h}(x+t).$$

volume of water and cone at time t	=	original volume of water	+	volume of submerged part of cone
$\pi R^2(H+x)$	=	$\pi R^2 H$	+	$\frac{1}{3}\pi r_1^2(x+t)$
$\pi R^2 H + \pi R^2 x$	=	$\pi R^2 H$	+	$\frac{1}{3}\pi \frac{r^2}{h^2}(x+t)^3$
$3h^2 R^2 x$	=	$r^2(x+t)^3$		

Differentiating implicitly with respect to t gives us

$$3h^2 R^2 \frac{dx}{dt} = r^2 \left[3(x+t)^2 \frac{dx}{dt} + 3(x+t)^2 \frac{dt}{dt} \right] \Rightarrow$$

$$\frac{dx}{dt} = \frac{r^2(x+t)^2}{h^2 R^2 - r^2(x+t)^2} \Rightarrow$$

$$\left. \frac{dx}{dt} \right|_{r+t=h} = \frac{r^2 h^2}{h^2 R^2 - r^2 h^2} = \frac{r^2}{R^2 - r^2}$$

Thus, the water level is rising at a rate of $\frac{r^2}{B^2 - r^2}$ cm/s at the instant the cone is completely submerged.

23.

By similar triangles, $\frac{r}{5} = \frac{h}{16} \Rightarrow r = \frac{5h}{16}$. The volume of the cone is

$V = \frac{1}{3}\pi r^2 h = \frac{1}{3}\pi \left(\frac{5h}{16}\right)^2 h = \frac{25\pi}{768}h^3$, so $\frac{dV}{dt} = \frac{25\pi}{256}h^2 \frac{dh}{dt}$. Now the rate of change of the volume is also equal to the difference of what is being added ($2 \text{ cm}^3/\text{min}$) and what is oozing out ($k\pi r l$, where $\pi r l$ is the area of the cone and k is a proportionality constant). Thus, $\frac{dV}{dt} = 2 - k\pi r l$.

Equating the two expressions for $\frac{dV}{dt}$ and substituting $h = 10$, $\frac{dh}{dt} = -0.3$, $r = \frac{5(10)}{16} = \frac{25}{8}$, and $\frac{l}{\sqrt{281}} = \frac{10}{16}$

$$\Leftrightarrow l = \frac{5}{8}\sqrt{281}, \text{ we get } \frac{25\pi}{256}(10)^2(-0.3) = 2 - k\pi \frac{25}{8} \cdot \frac{5}{8}\sqrt{281} \Leftrightarrow \frac{125k\pi\sqrt{281}}{64} = 2 + \frac{750\pi}{256}. \text{ Solving for } k$$

gives us $k = \frac{256 + 375\pi}{250\pi \sqrt{281}}$. To maintain a certain height, the rate of oozing, $k\pi r l$, must equal the rate of the liquid

being poured in; that is, $\frac{dV}{dt} = 0$. $k\pi r l = \frac{256 + 375\pi}{250\pi\sqrt{281}} \cdot \pi \cdot \frac{25}{8} \cdot \frac{5\sqrt{281}}{8} = \frac{256 + 375\pi}{128} \approx 11.204 \text{ cm}^3/\text{min}$.

- 24.** (a) $f(x) = x(x-2)(x-6) = x^3 - 8x^2 + 12x \Rightarrow f'(x) = 3x^2 - 16x + 12$. The average of the first pair of zeros is $(0+2)/2 = 1$. At $x = 1$, the slope of the tangent line is $f'(1) = -1$, so an equation of the tangent line has the form $y = -1x + b$. Since $f(1) = 5$, we have $5 = -1 + b \Rightarrow b = 6$ and the tangent has equation $y = -x + 6$. Similarly, at $x = \frac{0+6}{2} = 3$, $y = -9x + 18$; at $x = \frac{2+6}{2} = 4$, $y = -4x$. From the graph, we see that each tangent line drawn at the average of two zeros intersects the graph of f at the third zero.

- (b) A CAS gives $f'(x) = (x-b)(x-c) + (x-a)(x-c) + (x-a)(x-b)$ or

$f'(x) = 3x^2 - 2(a + b + c)x + ab + ac + bc$. Using the Simplify command, we get

$f'\left(\frac{a+b}{2}\right) = -\frac{(a-b)^2}{4}$ and $f\left(\frac{a+b}{2}\right) = -\frac{(a-b)^2}{8}(a+b-2c)$, so an equation of the tangent line at $x = \frac{a+b}{2}$ is

$$y = -\frac{(a-b)^2}{4}\left(x - \frac{a+b}{2}\right) - \frac{(a-b)^2}{8}(a+b-2c)$$

To find the x -intercept, let $y = 0$ and use the Solve command. The result is $x = c$.

Using Derive, we can begin by authoring the expression $(x-a)(x-b)(x-c)$. Now load the utility file Dif_apps. Next we author tangent (#1, $x, (a+b)/2$)—this is the command to find an equation of the tangent line of the function in #1 whose independent variable is x at the x -value $(a+b)/2$. We then simplify that expression and obtain the equation $y = \#3$. The form in expression #3 makes it easy to see that the x -intercept is the third zero, namely c . In a similar fashion we see that b is the x -intercept for the tangent line at $(a+c)/2$ and a is the x -intercept for the tangent line at $(b+c)/2$.

#1:	$(x - a) \cdot (x - b) \cdot (x - c)$	Author the function y=
#2:	$\text{TANGENT}\left[(x - a) \cdot (x - b) \cdot (x - c), x, \frac{a + b}{2}\right]$	Tangent(#1, x, (a+b)/2)

4 APPLICATIONS OF DIFFERENTIATION

4.1 Maximum and Minimum Values

1. A function f has an **absolute minimum** at $x = c$ if $f(c)$ is the smallest function value on the entire domain of f , whereas f has a **local minimum** at c if $f(c)$ is the smallest function value when x is near c .
2. (a) The Extreme Value Theorem
(b) See the Closed Interval Method.
3. Absolute maximum at b ; absolute minimum at d ; local maxima at b and e ; local minima at d and s ; neither a maximum nor a minimum at a , c , r , and t .
4. Absolute maximum at e ; absolute minimum at t ; local maxima at c , e , and s ; local minima at b , c , d , and r ; neither a maximum nor a minimum at a .
5. Absolute maximum value is $f(4) = 4$; absolute minimum value is $f(7) = 0$; local maximum values are $f(4) = 4$ and $f(6) = 3$; local minimum values are $f(2) = 1$ and $f(5) = 2$.
6. Absolute maximum value is $f(8) = 5$; absolute minimum value is $f(2) = 0$; local maximum values are $f(1) = 2$, $f(4) = 4$, and $f(6) = 3$; local minimum values are $f(2) = 0$, $f(5) = 2$, and $f(7) = 1$.
7. Absolute minimum at 2, absolute maximum at 3, local minimum at 4
8. Absolute minimum at 1, absolute maximum at 5, local maximum at 2, local minimum at 4

9. Absolute maximum at 5, absolute minimum at 2, local maximum at 3, local minima at 2 and 4

10. f has no local maximum or minimum, but 2 and 4 are critical numbers

11. (a)

(b)

(c)

12. (a) Note that a local maximum cannot occur at an endpoint.

(b)

Note: By the Extreme Value Theorem, f must not be continuous.

13. (a) Note: By the Extreme Value Theorem, f must not be continuous; because if it were, it would attain an absolute minimum.

(b)

14. (a)

(b)

15. $f(x) = 8 - 3x$, $x \geq 1$. Absolute maximum $f(1) = 5$; no local maximum. No absolute or local minimum.

16. $f(x) = 3 - 2x$, $x \leq 5$. Absolute minimum $f(5) = -7$; no local minimum. No absolute or local maximum.

17. $f(x) = x^2$, $0 < x < 2$. No absolute or local maximum or minimum value.

18. $f(x) = x^2$, $0 < x \leq 2$. Absolute maximum $f(2) = 4$; no local maximum. No absolute or local minimum.

19. $f(x) = x^2$, $0 \leq x < 2$. Absolute minimum $f(0) = 0$; no local minimum. No absolute or local maximum.

20. $f(x) = x^2$, $0 \leq x \leq 2$. Absolute maximum $f(2) = 4$. Absolute minimum $f(0) = 0$. No local maximum or minimum.

21. $f(x) = x^2$, $-3 \leq x \leq 2$. Absolute maximum $f(-3) = 9$. No local maximum. Absolute and local minimum $f(0) = 0$.

22. $f(x) = 1 + (x + 1)^2$, $-2 \leq x < 5$. No absolute or local maximum. Absolute and local minimum $f(-1) = 1$.

23. $f(t) = 1/t$, $0 < t < 1$. No maximum or minimum.

25. $f(\theta) = \sin \theta$, $-2\pi \leq \theta \leq 2\pi$. Absolute and local maxima $f(-\frac{3\pi}{2}) = f(\frac{\pi}{2}) = 1$. Absolute and local minima $f(-\frac{\pi}{2}) = f(\frac{3\pi}{2}) = -1$.

27. $f(x) = 1 - \sqrt{x}$. Absolute maximum $f(0) = 1$; no local maximum. No absolute or local minimum.

29. $f(x) = \begin{cases} 1 - x & \text{if } 0 \leq x < 2 \\ 2x - 4 & \text{if } 2 \leq x \leq 3 \end{cases}$

Absolute maximum $f(3) = 2$; no local maximum. No absolute or local minimum.

24. $f(t) = 1/t$, $0 < t \leq 1$. Absolute minimum $f(1) = 1$; no local minimum. No local or absolute maximum.

26. $f(\theta) = \tan \theta$, $-\frac{\pi}{4} \leq \theta < \frac{\pi}{2}$. Absolute minimum $f(-\frac{\pi}{4}) = -1$; no local minimum. No absolute or local maximum.

28. $f(x) = 1 - x^3$. No absolute or local extreme values.

30. $f(x) = \begin{cases} x^2 & \text{if } -1 \leq x < 0 \\ 2 - x^2 & \text{if } 0 \leq x \leq 1 \end{cases}$

Absolute and local maximum $f(0) = 2$. No absolute or local minimum.

31. $f(x) = 5x^2 + 4x \Rightarrow f'(x) = 10x + 4$. $f'(x) = 0 \Rightarrow x = -\frac{2}{5}$, so $-\frac{2}{5}$ is the only critical number.
32. $f(x) = x^3 + x^2 - x \Rightarrow f'(x) = 3x^2 + 2x - 1$. $f'(x) = 0 \Rightarrow (x+1)(3x-1) = 0 \Rightarrow x = -1, \frac{1}{3}$.
These are the only critical numbers.
33. $f(x) = x^3 + 3x^2 - 24x \Rightarrow f'(x) = 3x^2 + 6x - 24 = 3(x^2 + 2x - 8)$.
 $f'(x) = 0 \Rightarrow 3(x+4)(x-2) = 0 \Rightarrow x = -4, 2$. These are the only critical numbers.
34. $f(x) = x^3 + x^2 + x \Rightarrow f'(x) = 3x^2 + 2x + 1$. $f'(x) = 0 \Rightarrow 3x^2 + 2x + 1 = 0 \Rightarrow$
 $x = \frac{-2 \pm \sqrt{4-12}}{6}$. Neither of these is a real number. Thus, there are no critical numbers.
35. $s(t) = 3t^4 + 4t^3 - 6t^2 \Rightarrow s'(t) = 12t^3 + 12t^2 - 12t$. $s'(t) = 0 \Rightarrow 12t(t^2 + t - 1) \Rightarrow t = 0$ or
 $t^2 + t - 1 = 0$. Using the quadratic formula to solve the latter equation gives us
 $t = \frac{-1 \pm \sqrt{1^2 - 4(1)(-1)}}{2(1)} = \frac{-1 \pm \sqrt{5}}{2} \approx 0.618, -1.618$. The three critical numbers are $0, \frac{-1 \pm \sqrt{5}}{2}$.
36. $f(z) = \frac{z+1}{z^2+z+1} \Rightarrow f'(z) = \frac{(z^2+z+1) \cdot 1 - (z+1)(2z+1)}{(z^2+z+1)^2} = \frac{-z^2-2z}{(z^2+z+1)^2} = 0 \Leftrightarrow$
 $z(z+2) = 0 \Rightarrow z = 0, -2$ are the critical numbers. (Note that $z^2+z+1 \neq 0$ since the discriminant < 0 .)
37. $g(x) = |2x+3| = \begin{cases} 2x+3 & \text{if } 2x+3 \geq 0 \\ -(2x+3) & \text{if } 2x+3 < 0 \end{cases} \Rightarrow g'(x) = \begin{cases} 2 & \text{if } x > -\frac{3}{2} \\ -2 & \text{if } x < -\frac{3}{2} \end{cases}$
 $g'(x)$ is never 0, but $g'(x)$ does not exist for $x = -\frac{3}{2}$, so $-\frac{3}{2}$ is the only critical number.
38. $g(x) = x^{1/3} - x^{-2/3} \Rightarrow g'(x) = \frac{1}{3}x^{-2/3} + \frac{2}{3}x^{-5/3} = \frac{1}{3}x^{-5/3}(x+2) = \frac{x+2}{3x^{5/3}}$.
 $g'(-2) = 0$ and $g'(0)$ does not exist, but 0 is not in the domain of g , so the only critical number is -2 .
39. $g(t) = 5t^{2/3} + t^{5/3} \Rightarrow g'(t) = \frac{10}{3}t^{-1/3} + \frac{5}{3}t^{2/3}$. $g'(0)$ does not exist, so $t = 0$ is a critical number.
 $g'(t) = \frac{5}{3}t^{-1/3}(2+t) = 0 \Leftrightarrow t = -2$, so $t = -2$ is also a critical number.
40. $g(t) = \sqrt{t}(1-t) = t^{1/2} - t^{3/2} \Rightarrow g'(t) = \frac{1}{2\sqrt{t}} - \frac{3}{2}\sqrt{t}$. $g'(0)$ does not exist, so $t = 0$ is a critical number.
 $0 = g'(t) = \frac{1-3t}{2\sqrt{t}} \Rightarrow t = \frac{1}{3}$, so $t = \frac{1}{3}$ is also a critical number.
41. $F(x) = x^{4/5}(x-4)^2 \Rightarrow$
 $F'(x) = x^{4/5} \cdot 2(x-4) + (x-4)^2 \cdot \frac{4}{5}x^{-1/5} = \frac{1}{5}x^{-1/5}(x-4)[5 \cdot x \cdot 2 + (x-4) \cdot 4]$
 $= \frac{(x-4)(14x-16)}{5x^{1/5}} = \frac{2(x-4)(7x-8)}{5x^{1/5}} = 0$ when $x = 4, \frac{8}{7}$; and $F'(0)$ does not exist.
Critical numbers are $0, \frac{8}{7}, 4$.
42. $G(x) = \sqrt[3]{x^2-x} \Rightarrow G'(x) = \frac{1}{3}(x^2-x)^{-2/3}(2x-1)$. $G'(x)$ does not exist when $x^2-x = 0$, that is,
when $x = 0$ or 1 . $G'(x) = 0 \Leftrightarrow 2x-1 = 0 \Leftrightarrow x = \frac{1}{2}$. So the critical numbers are $x = 0, \frac{1}{2}, 1$.
43. $f(\theta) = 2\cos\theta + \sin^2\theta \Rightarrow f'(\theta) = -2\sin\theta + 2\sin\theta\cos\theta$. $f'(\theta) = 0 \Rightarrow 2\sin\theta(\cos\theta-1) = 0 \Rightarrow$
 $\sin\theta = 0$ or $\cos\theta = 1 \Rightarrow \theta = n\pi$ (n an integer) or $\theta = 2n\pi$. The solutions $\theta = n\pi$ include the solutions
 $\theta = 2n\pi$, so the critical numbers are $\theta = n\pi$.
44. $g(\theta) = 4\theta - \tan\theta \Rightarrow g'(\theta) = 4 - \sec^2\theta$. $g'(\theta) = 0 \Rightarrow \sec^2\theta = 4 \Rightarrow \sec\theta = \pm 2 \Rightarrow$
 $\cos\theta = \pm \frac{1}{2} \Rightarrow \theta = \frac{\pi}{3} + 2n\pi, \frac{5\pi}{3} + 2n\pi, \frac{2\pi}{3} + 2n\pi, \text{ and } \frac{4\pi}{3} + 2n\pi$ are critical numbers.
Note: The values of θ that make $g'(\theta)$ undefined are not in the domain of g .

45. $f(x) = 3x^2 - 12x + 5$, $[0, 3]$. $f'(x) = 6x - 12 = 0 \Leftrightarrow x = 2$. Applying the Closed Interval Method, we find that $f(0) = 5$, $f(2) = -7$, and $f(3) = -4$. So $f(0) = 5$ is the absolute maximum value and $f(2) = -7$ is the absolute minimum value.
46. $f(x) = x^3 - 3x + 1$, $[0, 3]$. $f'(x) = 3x^2 - 3 = 0 \Leftrightarrow x = \pm 1$, but -1 is not in $[0, 3]$. $f(0) = 1$, $f(1) = -1$, and $f(3) = 19$. So $f(3) = 19$ is the absolute maximum value and $f(1) = -1$ is the absolute minimum value.
47. $f(x) = 2x^3 - 3x^2 - 12x + 1$, $[-2, 3]$. $f'(x) = 6x^2 - 6x - 12 = 6(x^2 - x - 2) = 6(x - 2)(x + 1) = 0 \Leftrightarrow x = 2, -1$. $f(-2) = -3$, $f(-1) = 8$, $f(2) = -19$, and $f(3) = -8$. So $f(-1) = 8$ is the absolute maximum value and $f(2) = -19$ is the absolute minimum value.
48. $f(x) = x^3 - 6x^2 + 9x + 2$, $[-1, 4]$. $f'(x) = 3x^2 - 12x + 9 = 3(x^2 - 4x + 3) = 3(x - 1)(x - 3) = 0 \Leftrightarrow x = 1, 3$. $f(-1) = -14$, $f(1) = 6$, $f(3) = 2$, and $f(4) = 6$. So $f(1) = f(4) = 6$ is the absolute maximum value and $f(-1) = -14$ is the absolute minimum value.
49. $f(x) = x^4 - 2x^2 + 3$, $[-2, 3]$. $f'(x) = 4x^3 - 4x = 4x(x^2 - 1) = 4x(x + 1)(x - 1) = 0 \Leftrightarrow x = -1, 0, 1$. $f(-2) = 11$, $f(-1) = 2$, $f(0) = 3$, $f(1) = 2$, $f(3) = 66$. So $f(3) = 66$ is the absolute maximum value and $f(\pm 1) = 2$ is the absolute minimum value.
50. $f(x) = (x^2 - 1)^3$, $[-1, 2]$. $f'(x) = 3(x^2 - 1)^2(2x) = 6x(x + 1)^2(x - 1)^2 = 0 \Leftrightarrow x = -1, 0, 1$. $f(\pm 1) = 0$, $f(0) = -1$, and $f(2) = 27$. So $f(2) = 27$ is the absolute maximum value and $f(0) = -1$ is the absolute minimum value.
51. $f(x) = \frac{x}{x^2 + 1}$, $[0, 2]$. $f'(x) = \frac{(x^2 + 1) - x(2x)}{(x^2 + 1)^2} = \frac{1 - x^2}{(x^2 + 1)^2} = 0 \Leftrightarrow x = \pm 1$, but -1 is not in $[0, 2]$. $f(0) = 0$, $f(1) = \frac{1}{2}$, $f(2) = \frac{2}{5}$. So $f(1) = \frac{1}{2}$ is the absolute maximum value and $f(0) = 0$ is the absolute minimum value.
52. $f(x) = \frac{x^2 - 4}{x^2 + 4}$, $[-4, 4]$. $f'(x) = \frac{(x^2 + 4)(2x) - (x^2 - 4)(2x)}{(x^2 + 4)^2} = \frac{16x}{(x^2 + 4)^2} = 0 \Leftrightarrow x = 0$. $f(\pm 4) = \frac{12}{20} = \frac{3}{5}$ and $f(0) = -1$. So $f(\pm 4) = \frac{3}{5}$ is the absolute maximum value and $f(0) = -1$ is the absolute minimum value.
53. $f(t) = t\sqrt{4 - t^2}$, $[-1, 2]$.
 $f'(t) = t \cdot \frac{1}{2}(4 - t^2)^{-1/2}(-2t) + (4 - t^2)^{1/2} \cdot 1 = \frac{-t^2}{\sqrt{4 - t^2}} + \sqrt{4 - t^2} = \frac{-t^2 + (4 - t^2)}{\sqrt{4 - t^2}} = \frac{4 - 2t^2}{\sqrt{4 - t^2}}$.
 $f'(t) = 0 \Rightarrow 4 - 2t^2 = 0 \Rightarrow t^2 = 2 \Rightarrow t = \pm\sqrt{2}$, but $t = -\sqrt{2}$ is not in the given interval, $[-1, 2]$.
 $f'(t)$ does not exist if $4 - t^2 = 0 \Rightarrow t = \pm 2$, but -2 is not in the given interval. $f(-1) = -\sqrt{3}$, $f(\sqrt{2}) = 2$, and $f(2) = 0$. So $f(\sqrt{2}) = 2$ is the absolute maximum value and $f(-1) = -\sqrt{3}$ is the absolute minimum value.
54. $f(t) = \sqrt[3]{t}(8 - t)$, $[0, 8]$. $f(t) = 8t^{1/3} - t^{4/3} \Rightarrow f'(t) = \frac{8}{3}t^{-2/3} - \frac{4}{3}t^{1/3} = \frac{4}{3}t^{-2/3}(2 - t) = \frac{4(2 - t)}{3\sqrt[3]{t^2}}$.
 $f'(t) = 0 \Rightarrow t = 2$. $f'(t)$ does not exist if $t = 0$. $f(0) = 0$, $f(2) = 6\sqrt[3]{2} \approx 7.56$, and $f(8) = 0$.
 So $f(2) = 6\sqrt[3]{2}$ is the absolute maximum value and $f(0) = f(8) = 0$ is the absolute minimum value.
55. $f(x) = \sin x + \cos x$, $[0, \frac{\pi}{3}]$. $f'(x) = \cos x - \sin x = 0 \Leftrightarrow \sin x = \cos x \Rightarrow \frac{\sin x}{\cos x} = 1 \Rightarrow \tan x = 1 \Rightarrow x = \frac{\pi}{4}$. $f(0) = 1$, $f(\frac{\pi}{4}) = \sqrt{2} \approx 1.41$, $f(\frac{\pi}{3}) = \frac{\sqrt{3}+1}{2} \approx 1.37$. So $f(\frac{\pi}{4}) = \sqrt{2}$ is the absolute maximum value and $f(0) = 1$ is the absolute minimum value.

56. $f(x) = x - 2 \cos x, [-\pi, \pi]$. $f'(x) = 1 + 2 \sin x = 0 \Leftrightarrow \sin x = -\frac{1}{2} \Leftrightarrow x = -\frac{5\pi}{6}, -\frac{\pi}{6}$.

$$f(-\pi) = 2 - \pi \approx -1.14, f(-\frac{5\pi}{6}) = \sqrt{3} - \frac{5\pi}{6} \approx -0.886, f(-\frac{\pi}{6}) = -\frac{\pi}{6} - \sqrt{3} \approx -2.26,$$

$f(\pi) = \pi + 2 \approx 5.14$. So $f(\pi) = \pi + 2$ is the absolute maximum value and $f(-\frac{\pi}{6}) = -\frac{\pi}{6} - \sqrt{3}$ is the absolute minimum value.

57. $f(x) = x^a(1-x)^b, 0 \leq x \leq 1, a > 0, b > 0$.

$$\begin{aligned} f'(x) &= x^a \cdot b(1-x)^{b-1}(-1) + (1-x)^b \cdot ax^{a-1} = x^{a-1}(1-x)^{b-1} [x \cdot b(-1) + (1-x) \cdot a] \\ &= x^{a-1}(1-x)^{b-1}(a - ax - bx) \end{aligned}$$

At the endpoints, we have $f(0) = f(1) = 0$ [the minimum value of f]. In the interval $(0, 1)$, $f'(x) = 0 \Leftrightarrow x = \frac{a}{a+b}$.

$$f\left(\frac{a}{a+b}\right) = \left(\frac{a}{a+b}\right)^a \left(1 - \frac{a}{a+b}\right)^b = \frac{a^a}{(a+b)^a} \left(\frac{a+b-a}{a+b}\right)^b = \frac{a^a}{(a+b)^a} \cdot \frac{b^b}{(a+b)^b} = \frac{a^a b^b}{(a+b)^{a+b}}.$$

So $f\left(\frac{a}{a+b}\right) = \frac{a^a b^b}{(a+b)^{a+b}}$ is the absolute maximum value.

58.

We see that $f'(x) = 0$ at about $x = 0.0$ and 2.0 , and that $f'(x)$ does not exist at about $x = -0.7, 1.0$, and 2.7 , so the critical numbers of f are about $-0.7, 0.0, 1.0, 2.0$, and 2.7 .

59. (a)

From the graph, it appears that the absolute maximum value is about $f(-1.63) = 9.71$, and the absolute minimum value is about $f(1.63) = -7.71$. These values make sense because the graph is symmetric about the point $(0, 1)$. ($y = x^3 - 8x$ is symmetric about the origin.)

(b) $f(x) = x^3 - 8x + 1 \Rightarrow f'(x) = 3x^2 - 8$. So $f'(x) = 0 \Rightarrow x = \pm\sqrt{\frac{8}{3}}$.

$$\begin{aligned} f\left(\pm\sqrt{\frac{8}{3}}\right) &= \left(\pm\sqrt{\frac{8}{3}}\right)^3 - 8\left(\pm\sqrt{\frac{8}{3}}\right) + 1 = \pm\frac{8}{3}\sqrt{\frac{8}{3}} \mp 8\sqrt{\frac{8}{3}} + 1 \\ &= -\frac{16}{3}\sqrt{\frac{8}{3}} + 1 = 1 - \frac{32\sqrt{6}}{9} \text{ [minimum]} \quad \text{or} \quad \frac{16}{3}\sqrt{\frac{8}{3}} + 1 = 1 + \frac{32\sqrt{6}}{9} \text{ [maximum]} \end{aligned}$$

(From the graph, we see that the extreme values do not occur at the endpoints.)

60. (a)

From the graph, it appears that the absolute maximum value is $f(2) = 2$, and that the absolute minimum value is about $f(0.25) = -0.11$.

(b) $f(x) = x^4 - 3x^3 + 3x^2 - x \Rightarrow f'(x) = 4x^3 - 9x^2 + 6x - 1 = (4x-1)(x-1)^2$.

So $f'(x) = 0 \Rightarrow x = \frac{1}{4}$ or $x = 1$. Now $f(1) = 1^4 - 3 \cdot 1^3 + 3 \cdot 1^2 - 1 = 0$ (not an extremum)

and $f(\frac{1}{4}) = (\frac{1}{4})^4 - 3(\frac{1}{4})^3 + 3(\frac{1}{4})^2 - \frac{1}{4} = -\frac{27}{256}$ (minimum). At the right endpoint we have $f(2) = 2^4 - 3 \cdot 2^3 + 3 \cdot 2^2 - 2 = 2$ (maximum).

61. (a)

From the graph, it appears that the absolute maximum value is about

$f(0.75) = 0.32$, and the absolute minimum value is

$f(0) = f(1) = 0$; that is, at both endpoints.

$$(b) f(x) = x\sqrt{x-x^2} \Rightarrow f'(x) = x \cdot \frac{1-2x}{2\sqrt{x-x^2}} + \sqrt{x-x^2} = \frac{(x-2x^2) + (2x-2x^2)}{2\sqrt{x-x^2}} = \frac{3x-4x^2}{2\sqrt{x-x^2}}.$$

$$\text{So } f'(x) = 0 \Rightarrow 3x - 4x^2 = 0 \Rightarrow x(3-4x) = 0 \Rightarrow x = 0 \text{ or } \frac{3}{4}. \quad f(0) = f(1) = 0 \text{ [minimum],}$$

$$\text{and } f(\frac{3}{4}) = \frac{3}{4}\sqrt{\frac{3}{4} - (\frac{3}{4})^2} = \frac{3\sqrt{3}}{16} \text{ [maximum].}$$

62. (a)

From the graph, it appears that the absolute maximum value is about

$f(5.76) = 0.58$, and the absolute minimum value is about

$f(3.67) = -0.58$.

$$(b) f(x) = \frac{\cos x}{2 + \sin x} \Rightarrow f'(x) = \frac{(2 + \sin x)(-\sin x) - (\cos x)(\cos x)}{(2 + \sin x)^2} = \frac{-1 - 2\sin x}{(2 + \sin x)^2}.$$

$$\text{So } f'(x) = 0 \Rightarrow \sin x = -\frac{1}{2} \Rightarrow x = \frac{7\pi}{6} \text{ or } \frac{11\pi}{6}. \text{ Now } f(\frac{7\pi}{6}) = \frac{-\sqrt{3}/2}{3/2} = -\frac{1}{\sqrt{3}} \text{ [minimum],}$$

$$\text{and } f(\frac{11\pi}{6}) = \frac{\sqrt{3}/2}{3/2} = \frac{1}{\sqrt{3}} \text{ [maximum].}$$

63. The density is defined as $\rho = \frac{\text{mass}}{\text{volume}} = \frac{1000}{V(T)}$ (in g/cm³). But a critical point of ρ will also be a critical point

of V [since $\frac{d\rho}{dT} = -1000V^{-2}\frac{dV}{dT}$ and V is never 0], and V is easier to differentiate than ρ .

$$V(T) = 999.87 - 0.06426T + 0.0085043T^2 - 0.0000679T^3 \Rightarrow$$

$V'(T) = -0.06426 + 0.0170086T - 0.0002037T^2$. Setting this equal to 0 and using the quadratic formula to

$$\text{find } T, \text{ we get } T = \frac{-0.0170086 \pm \sqrt{0.0170086^2 - 4 \cdot 0.0002037 \cdot 0.06426}}{2(-0.0002037)} \approx 3.9665^\circ\text{C or } 79.5318^\circ\text{C. Since}$$

we are only interested in the region $0^\circ\text{C} \leq T \leq 30^\circ\text{C}$, we check the density ρ at the endpoints and at 3.9665°C :

$$\rho(0) \approx \frac{1000}{999.87} \approx 1.00013; \rho(30) \approx \frac{1000}{1003.7628} \approx 0.99625; \rho(3.9665) \approx \frac{1000}{999.7447} \approx 1.000255. \text{ So water has its maximum density at about } 3.9665^\circ\text{C.}$$

$$64. F = \frac{\mu W}{\mu \sin \theta + \cos \theta} \Rightarrow \frac{dF}{d\theta} = \frac{(\mu \sin \theta + \cos \theta)(0) - \mu W(\mu \cos \theta - \sin \theta)}{(\mu \sin \theta + \cos \theta)^2} = \frac{-\mu W(\mu \cos \theta - \sin \theta)}{(\mu \sin \theta + \cos \theta)^2}.$$

So $\frac{dF}{d\theta} = 0 \Rightarrow \mu \cos \theta - \sin \theta = 0 \Rightarrow \mu = \frac{\sin \theta}{\cos \theta} = \tan \theta$. Substituting $\tan \theta$ for μ in F gives us

$$F = \frac{(\tan \theta)W}{(\tan \theta) \sin \theta + \cos \theta} = \frac{W \tan \theta}{\frac{\sin^2 \theta}{\cos \theta} + \cos \theta} = \frac{W \tan \theta \cos \theta}{\sin^2 \theta + \cos^2 \theta} = \frac{W \sin \theta}{1} = W \sin \theta.$$

If $\tan \theta = \mu$, then $\sin \theta = \frac{\mu}{\sqrt{\mu^2 + 1}}$ (see the figure), so $F = \frac{\mu}{\sqrt{\mu^2 + 1}}W$. We

compare this with the value of F at the endpoints: $F(0) = \mu W$ and $F(\frac{\pi}{2}) = W$.

Now because $\frac{\mu}{\sqrt{\mu^2 + 1}} \leq 1$ and $\frac{\mu}{\sqrt{\mu^2 + 1}} \leq \mu$, we have that $\frac{\mu}{\sqrt{\mu^2 + 1}}W$

is less than or equal to each of $F(0)$ and $F(\frac{\pi}{2})$. Hence, $\frac{\mu}{\sqrt{\mu^2 + 1}}W$ is the absolute minimum value of $F(\theta)$, and it occurs when $\tan \theta = \mu$.

65. We apply the Closed Interval Method to the continuous function

$I(t) = 0.00009045t^5 + 0.001438t^4 - 0.06561t^3 + 0.4598t^2 - 0.6270t + 99.33$ on $[0, 10]$. Its derivative is $I'(t) = 0.00045225t^4 + 0.005752t^3 - 0.19683t^2 + 0.9196t - 0.6270$. Since I' exists for all t , the only critical numbers of I occur when $I'(t) = 0$. We use a root-finder on a computer algebra system (or a graphing device) to find that $I'(t) = 0$ when $t \approx -29.7186, 0.8231, 5.1309$, or 11.0459 , but only the second and third roots lie in the interval $[0, 10]$. The values of I at these critical numbers are $I(0.8231) \approx 99.09$ and $I(5.1309) \approx 100.67$. The values of I at the endpoints of the interval are $I(0) = 99.33$ and $I(10) \approx 96.86$. Comparing these four numbers, we see that food was most expensive at $t \approx 5.1309$ (corresponding roughly to August, 1989) and cheapest at $t = 10$ (midyear 1994).

66. (a)

The equation of the graph in the figure is

$$v(t) = 0.00146t^3 - 0.11553t^2 + 24.98169t - 21.26872.$$

$$(b) a(t) = v'(t) = 0.00438t^2 - 0.23106t + 24.98169 \Rightarrow a'(t) = 0.00876t - 0.23106. a'(t) = 0 \Rightarrow$$

$$t_1 = \frac{0.23106}{0.00876} \approx 26.4. a(0) \approx 24.98, a(t_1) \approx 21.93, \text{ and } a(125) \approx 64.54. \text{ The maximum acceleration is about}$$

64.5 ft/s² and the minimum acceleration is about 21.93 ft/s².

67. (a) $v(r) = k(r_0 - r)r^2 = kr_0r^2 - kr^3 \Rightarrow v'(r) = 2kr_0r - 3kr^2. v'(r) = 0 \Rightarrow kr(2r_0 - 3r) = 0$
 $\Rightarrow r = 0$ or $\frac{2}{3}r_0$ (but 0 is not in the interval). Evaluating v at $\frac{1}{2}r_0, \frac{2}{3}r_0$, and r_0 , we get $v(\frac{1}{2}r_0) = \frac{1}{8}kr_0^3$,
 $v(\frac{2}{3}r_0) = \frac{4}{27}kr_0^3$, and $v(r_0) = 0$. Since $\frac{4}{27} > \frac{1}{8}$, v attains its maximum value at $r = \frac{2}{3}r_0$. This supports the statement in the text.

(b) From part (a), the maximum value of v is $\frac{4}{27}kr_0^3$.

68. $g(x) = 2 + (x - 5)^3 \Rightarrow g'(x) = 3(x - 5)^2 \Rightarrow g'(5) = 0$, so 5 is a critical number. But $g(5) = 2$ and g takes on values > 2 and values < 2 in any open interval containing 5, so g does not have a local maximum or minimum at 5.
69. $f(x) = x^{101} + x^{51} + x + 1 \Rightarrow f'(x) = 101x^{100} + 51x^{50} + 1 \geq 1$ for all x , so $f'(x) = 0$ has no solution. Thus, $f(x)$ has no critical number, so $f(x)$ can have no local maximum or minimum.
70. Suppose that f has a minimum value at c , so $f(x) \geq f(c)$ for all x near c . Then $g(x) = -f(x) \leq -f(c) = g(c)$ for all x near c , so $g(x)$ has a maximum value at c .
71. If f has a local minimum at c , then $g(x) = -f(x)$ has a local maximum at c , so $g'(c) = 0$ by the case of Fermat's Theorem proved in the text. Thus, $f'(c) = -g'(c) = 0$.
72. (a) $f(x) = ax^3 + bx^2 + cx + d$, $a \neq 0$. So $f'(x) = 3ax^2 + 2bx + c$ is a quadratic and hence has either 2, 1, or 0 real roots, so $f(x)$ has either 2, 1 or 0 critical numbers.

Case (i) (2 critical numbers):

$$f(x) = x^3 - 3x \Rightarrow f'(x) = 3x^2 - 3, \text{ so } x = -1, 1 \text{ are critical numbers.}$$

Case (ii) (1 critical number):

$$f(x) = x^3 \Rightarrow f'(x) = 3x^2, \text{ so } x = 0 \text{ is the only critical number.}$$

Case (iii) (no critical number):

$$f(x) = x^3 + 3x \Rightarrow f'(x) = 3x^2 + 3, \text{ so there are no real roots.}$$

- (b) Since there are at most two critical numbers, it can have at most two local extreme values and by (i) this can occur. By (iii) it can have no local extreme value. However, if there is only one critical number, then there is no local extreme value.

APPLIED PROJECT The Calculus of Rainbows

1. From Snell's Law, we have $\sin \alpha = \frac{4}{3} \sin \beta \Rightarrow \frac{d}{d\alpha}(\sin \alpha) = \frac{4}{3} \frac{d}{d\alpha}(\sin \beta) \Rightarrow \cos \alpha = \frac{4}{3} \cos \beta \frac{d\beta}{d\alpha} \Rightarrow \frac{d\beta}{d\alpha} = \frac{3 \cos \alpha}{4 \cos \beta}$. Now $D(\alpha) = \pi + 2\alpha - 4\beta \Rightarrow D'(\alpha) = 2 - 4 \frac{d\beta}{d\alpha} = 2 - 3 \frac{\cos \alpha}{\cos \beta}$. So $D'(\alpha) = 0 \Leftrightarrow 2 \cos \beta = 3 \cos \alpha$. Thus, $4 \cos^2 \beta = 9 \cos^2 \alpha \Rightarrow 4 - 4 \sin^2 \beta = 9 - 9 \sin^2 \alpha$. Since $3 \sin \alpha = 4 \sin \beta$, $\sin \beta = \frac{3}{4} \sin \alpha \Rightarrow 4 - 4 \left(\frac{3}{4} \sin \alpha\right)^2 = 9 - 9 \sin^2 \alpha \Rightarrow \left(9 - \frac{9}{4}\right) \sin^2 \alpha = 9 - 4 = 5 \Rightarrow \sin^2 \alpha = \frac{20}{27} \Rightarrow \sin \alpha = \sqrt{\frac{20}{27}}$. So $\alpha \approx 1.037$ radians or 59.4° . We show that this α does give the minimum on $[0, \frac{\pi}{2}]$: When $\alpha = 0$, $\sin \alpha = \frac{4}{3} \sin \beta \Rightarrow \beta = 0$, or $D(0) = \pi \approx 3.14$. When $\alpha = \frac{\pi}{2}$, $1 = \sin \frac{\pi}{2} = \frac{4}{3} \sin \beta \Rightarrow \sin \beta = \frac{3}{4} \Rightarrow \beta \approx 0.85$. So $D(\frac{\pi}{2}) \approx \pi + \pi - 4(0.85) \approx 2.88$. For $\alpha \approx 1.037$, $\sin \beta = \frac{3}{4} \sin \alpha = \frac{3}{4} \sqrt{\frac{20}{27}}$, so $\beta \approx 0.702 \Rightarrow D(\alpha) \approx \pi + 2(1.036) - 4(0.702) \approx 2.41$. So the minimum occurs when $\alpha \approx 1.04$ radians or 59.4° .

2. We repeat Problem 1 with k in place of $\frac{4}{3}$. So $\sin \alpha = k \sin \beta \Rightarrow \frac{d\beta}{d\alpha} = \frac{1}{k} \frac{\cos \alpha}{\cos \beta}$. Then

$$D'(\alpha) = 2 - 4 \frac{d\beta}{d\alpha} = 2 - \frac{4 \cos \alpha}{k \cos \beta} \text{ and } D'(\alpha) = 0 \Leftrightarrow k \cos \beta = 2 \cos \alpha. \text{ So } k^2 \cos^2 \beta = 4 \cos^2 \alpha \Rightarrow$$

$$k^2 - k^2 \sin^2 \beta = 4 - 4 \sin^2 \alpha \Rightarrow k^2 - \sin^2 \alpha = 4 - 4 \sin^2 \alpha \Rightarrow 3 \sin^2 \alpha = 4 - k^2 \Rightarrow$$

$$\sin \alpha = \sqrt{\frac{4 - k^2}{3}}. \text{ So for } k \approx 1.3318 \text{ (red light) the minimum occurs when } \sin \alpha_1 = \sqrt{\frac{4 - (1.3318)^2}{3}} \text{ or}$$

$\alpha_1 \approx 1.038$ radians, so the rainbow angle is about $\pi - D(\alpha_1) \approx 42.3^\circ$. For $k \approx 1.3435$ (violet light) the minimum occurs at $\alpha_2 \approx 1.026$ radians, and so the rainbow angle is about $\pi - D(\alpha_2) \approx 40.6^\circ$.

3. At each reflection or refraction, the light is bent in a counterclockwise direction: the bend at A is $\alpha - \beta$, the bend at B is $\pi - 2\beta$, the bend at C is again $\pi - 2\beta$, and the bend at D is $\alpha - \beta$. So the total bend is

$$D(\alpha) = 2(\alpha - \beta) + 2(\pi - 2\beta) = 2\alpha - 6\beta + 2\pi, \text{ as required. Now } \sin \alpha = k \sin \beta \Rightarrow \frac{d\beta}{d\alpha} = \frac{1}{k} \frac{\cos \alpha}{\cos \beta}. \text{ So}$$

$$D'(\alpha) = 2 - 6 \frac{d\beta}{d\alpha} = 2 - \frac{6 \cos \alpha}{k \cos \beta} \text{ and } D'(\alpha) = 0 \Leftrightarrow k \cos \beta = 3 \cos \alpha. \text{ So } k^2 \cos^2 \beta = 9 \cos^2 \alpha \Rightarrow$$

$$k^2 - k^2 \sin^2 \beta = 9 - 9 \sin^2 \alpha \Rightarrow k^2 - \sin^2 \alpha = 9 - 9 \sin^2 \alpha \Rightarrow \sin^2 \alpha = \frac{9 - k^2}{8} \Rightarrow$$

$$\sin \alpha = \sqrt{\frac{9 - k^2}{8}}. \text{ If } k = \frac{4}{3}, \text{ then the minimum occurs when } \sin \alpha_1 = \sqrt{\frac{9 - (4/3)^2}{8}} \text{ or } \alpha_1 \approx 1.254 \text{ radians.}$$

Thus, the minimum *counterclockwise* rotation is $D(\alpha_1) \approx 231^\circ$, which is equivalent to a *clockwise* rotation of $360^\circ - 231^\circ = 129^\circ$ (see the figure).

So the rainbow angle for the secondary rainbow is about

$180^\circ - 129^\circ = 51^\circ$, as required. In general, the rainbow angle for the

secondary rainbow is $\pi - [2\pi - D(\alpha)] = D(\alpha) - \pi$.

4. In the primary rainbow, the rainbow angle gets smaller as k gets larger, as we found in Problem 2, so the colors appear from top to bottom in order of increasing k . But in the secondary rainbow, the rainbow angle gets larger as k gets larger. To see this, we find the minimum deviations for red light and for violet light in the secondary rainbow.

For $k \approx 1.3318$ (red light) the minimum occurs when $\sin \alpha_1 = \sqrt{\frac{9 - 1.3318^2}{8}}$ or $\alpha_1 \approx 1.254$ radians, and so the rainbow angle is $D(\alpha_1) - \pi \approx 50.6^\circ$. For $k \approx 1.3435$ (violet light) the minimum occurs when

$\sin \alpha_2 = \sqrt{\frac{9 - 1.3435^2}{8}}$ or $\alpha_2 \approx 1.248$ radians, and so the rainbow angle is $D(\alpha_2) - \pi \approx 53.6^\circ$. Consequently, the rainbow angle is larger for colors with higher indices of refraction, and the colors appear from bottom to top in order of increasing k , the reverse of their order in the primary rainbow.

Note that our calculations above also explain why the secondary rainbow is more spread-out than the primary rainbow: in the primary rainbow, the difference between rainbow angles for red and violet light is about 1.7° , whereas in the secondary rainbow it is about 3° .

4.2 The Mean Value Theorem

1. $f(x) = x^2 - 4x + 1$, $[0, 4]$. Since f is a polynomial, it is continuous and differentiable on $\mathbb{R}$, so it is continuous on $[0, 4]$ and differentiable on $(0, 4)$. Also, $f(0) = 1 = f(4)$. $f'(c) = 0 \Leftrightarrow 2c - 4 = 0 \Leftrightarrow c = 2$, which is in the open interval $(0, 4)$, so $c = 2$ satisfies the conclusion of Rolle's Theorem.
2. $f(x) = x^3 - 3x^2 + 2x + 5$, $[0, 2]$. f is continuous on $[0, 2]$ and differentiable on $(0, 2)$. Also, $f(0) = 5 = f(2)$.
 $f'(c) = 0 \Leftrightarrow 3c^2 - 6c + 2 = 0 \Leftrightarrow c = \frac{6 \pm \sqrt{36 - 24}}{6} = 1 \pm \frac{1}{3}\sqrt{3}$, both in $(0, 2)$.
3. $f(x) = \sin 2\pi x$, $[-1, 1]$. f , being the composite of the sine function and the polynomial $2\pi x$, is continuous and differentiable on $\mathbb{R}$, so it is continuous on $[-1, 1]$ and differentiable on $(-1, 1)$. Also, $f(-1) = 0 = f(1)$.
 $f'(c) = 0 \Leftrightarrow 2\pi \cos 2\pi c = 0 \Leftrightarrow \cos 2\pi c = 0 \Leftrightarrow 2\pi c = \pm \frac{\pi}{2} + 2\pi n \Leftrightarrow c = \pm \frac{1}{4} + n$. If $n = 0$ or ± 1 , then $c = \pm \frac{1}{4}, \pm \frac{3}{4}$ is in $(-1, 1)$.
4. $f(x) = x\sqrt{x+6}$, $[-6, 0]$. f is continuous on its domain, $[-6, \infty)$, and differentiable on $(-6, \infty)$, so it is continuous on $[-6, 0]$ and differentiable on $(-6, 0)$. Also, $f(-6) = 0 = f(0)$. $f'(c) = 0 \Leftrightarrow \frac{3c + 12}{2\sqrt{c+6}} = 0$
 $\Leftrightarrow c = -4$, which is in $(-6, 0)$.
5. $f(x) = 1 - x^{2/3}$. $f(-1) = 1 - (-1)^{2/3} = 1 - 1 = 0 = f(1)$. $f'(x) = -\frac{2}{3}x^{-1/3}$, so $f'(c) = 0$ has no solution. This does not contradict Rolle's Theorem, since $f'(0)$ does not exist, and so f is not differentiable on $(-1, 1)$.
6. $f(x) = (x-1)^{-2}$. $f(0) = (0-1)^{-2} = 1 = (2-1)^{-2} = f(2)$. $f'(x) = -2(x-1)^{-3} \Rightarrow f'(x)$ is never 0. This does not contradict Rolle's Theorem since $f'(1)$ does not exist.

13. $f(x) = \sqrt[3]{x}$, $[0, 1]$. f is continuous on $\mathbb{R}$ and differentiable on $(-\infty, 0) \cup (0, \infty)$, so f is continuous on $[0, 1]$ and differentiable on $(0, 1)$. $f'(c) = \frac{f(b) - f(a)}{b - a} \Leftrightarrow \frac{1}{3c^{2/3}} = \frac{f(1) - f(0)}{1 - 0} \Leftrightarrow \frac{1}{3c^{2/3}} = \frac{1 - 0}{1} \Leftrightarrow 3c^{2/3} = 1 \Leftrightarrow c^{2/3} = \frac{1}{3} \Leftrightarrow c^2 = \left(\frac{1}{3}\right)^3 = \frac{1}{27} \Leftrightarrow c = \pm\sqrt{\frac{1}{27}} = \pm\frac{\sqrt{3}}{9}$, but only $\frac{\sqrt{3}}{9}$ is in $(0, 1)$.
14. $f(x) = \frac{x}{x+2}$, $[1, 4]$. f is continuous on $[1, 4]$ and differentiable on $(1, 4)$. $f'(c) = \frac{f(b) - f(a)}{b - a} \Leftrightarrow \frac{2}{(c+2)^2} = \frac{\frac{2}{3} - \frac{1}{3}}{4 - 1} \Leftrightarrow (c+2)^2 = 18 \Leftrightarrow c = -2 \pm 3\sqrt{2}$. $-2 + 3\sqrt{2} \approx 2.24$ is in $(1, 4)$.
15. $f(x) = |x - 1|$. $f(3) - f(0) = |3 - 1| - |0 - 1| = 1$. Since $f'(c) = -1$ if $c < 1$ and $f'(c) = 1$ if $c > 1$, $f'(c)(3 - 0) = \pm 3$ and so is never equal to 1. This does not contradict the Mean Value Theorem since $f'(1)$ does not exist.
16. $f(x) = \frac{x+1}{x-1}$. $f(2) - f(0) = 3 - (-1) = 4$. $f'(x) = \frac{1(x-1) - 1(x+1)}{(x-1)^2} = \frac{-2}{(x-1)^2}$. Since $f'(x) < 0$ for all x (except $x = 1$), $f'(c)(2 - 0)$ is always < 0 and hence cannot equal 4. This does not contradict the Mean Value Theorem since f is not continuous at $x = 1$.
17. Let $f(x) = 1 + 2x + x^3 + 4x^5$. Then $f(-1) = -6 < 0$ and $f(0) = 1 > 0$. Since f is a polynomial, it is continuous, so the Intermediate Value Theorem says that there is a number c between -1 and 0 such that $f(c) = 0$. Thus, the given equation has a real root. Suppose the equation has distinct real roots a and b with $a < b$. Then $f(a) = f(b) = 0$. Since f is a polynomial, it is differentiable on (a, b) and continuous on $[a, b]$. By Rolle's Theorem, there is a number r in (a, b) such that $f'(r) = 0$. But $f'(x) = 2 + 3x^2 + 20x^4 \geq 2$ for all x , so $f'(x)$ can never be 0. This contradiction shows that the equation can't have two distinct real roots. Hence, it has exactly one real root.
18. Let $f(x) = 2x - 1 - \sin x$. Then $f(0) = -1 < 0$ and $f(\pi/2) = \pi - 2 > 0$. f is the sum of the polynomial $2x - 1$ and the scalar multiple $(-1) \cdot \sin x$ of the trigonometric function $\sin x$, so f is continuous (and differentiable) for all x . By the Intermediate Value Theorem, there is a number c in $(0, \pi/2)$ such that $f(c) = 0$. Thus, the given equation has at least one real root. If the equation has distinct real roots a and b with $a < b$, then $f(a) = f(b) = 0$. Since f is continuous on $[a, b]$ and differentiable on (a, b) , Rolle's Theorem implies that there is a number r in (a, b) such that $f'(r) = 0$. But $f'(r) = 2 - \cos r > 0$ since $\cos r \leq 1$. This contradiction shows that the given equation can't have two distinct real roots, so it has exactly one real root.
19. Let $f(x) = x^3 - 15x + c$ for x in $[-2, 2]$. If f has two real roots a and b in $[-2, 2]$, with $a < b$, then $f(a) = f(b) = 0$. Since the polynomial f is continuous on $[a, b]$ and differentiable on (a, b) , Rolle's Theorem implies that there is a number r in (a, b) such that $f'(r) = 0$. Now $f'(r) = 3r^2 - 15$. Since r is in (a, b) , which is contained in $[-2, 2]$, we have $|r| < 2$, so $r^2 < 4$. It follows that $3r^2 - 15 < 3 \cdot 4 - 15 = -3 < 0$. This contradicts $f'(r) = 0$, so the given equation can't have two real roots in $[-2, 2]$. Hence, it has at most one real root in $[-2, 2]$.
20. $f(x) = x^4 + 4x + c$. Suppose that $f(x) = 0$ has three distinct real roots a, b, d where $a < b < d$. Then $f(a) = f(b) = f(d) = 0$. By Rolle's Theorem there are numbers c_1 and c_2 with $a < c_1 < b$ and $b < c_2 < d$ and $0 = f'(c_1) = f'(c_2)$, so $f'(x) = 0$ must have at least two real solutions. However $0 = f'(x) = 4x^3 + 4 = 4(x^3 + 1) = 4(x + 1)(x^2 - x + 1)$ has as its only real solution $x = -1$. Thus, $f(x)$ can have at most two real roots.

21. (a) Suppose that a cubic polynomial $P(x)$ has roots $a_1 < a_2 < a_3 < a_4$, so $P(a_1) = P(a_2) = P(a_3) = P(a_4)$. By Rolle's Theorem there are numbers c_1, c_2, c_3 with $a_1 < c_1 < a_2$, $a_2 < c_2 < a_3$ and $a_3 < c_3 < a_4$ and $P'(c_1) = P'(c_2) = P'(c_3) = 0$. Thus, the second-degree polynomial $P'(x)$ has three distinct real roots, which is impossible.
- (b) We prove by induction that a polynomial of degree n has at most n real roots. This is certainly true for $n = 1$. Suppose that the result is true for all polynomials of degree n and let $P(x)$ be a polynomial of degree $n + 1$. Suppose that $P(x)$ has more than $n + 1$ real roots, say $a_1 < a_2 < a_3 < \cdots < a_{n+1} < a_{n+2}$. Then $P(a_1) = P(a_2) = \cdots = P(a_{n+2}) = 0$. By Rolle's Theorem there are real numbers $c_1, \dots, c_{n+1}$ with $a_1 < c_1 < a_2, \dots, a_{n+1} < c_{n+1} < a_{n+2}$ and $P'(c_1) = \cdots = P'(c_{n+1}) = 0$. Thus, the n th degree polynomial $P'(x)$ has at least $n + 1$ roots. This contradiction shows that $P(x)$ has at most $n + 1$ real roots.
22. (a) Suppose that $f(a) = f(b) = 0$ where $a < b$. By Rolle's Theorem applied to f on $[a, b]$ there is a number c such that $a < c < b$ and $f'(c) = 0$.
- (b) Suppose that $f(a) = f(b) = f(c) = 0$ where $a < b < c$. By Rolle's Theorem applied to $f(x)$ on $[a, b]$ and $[b, c]$ there are numbers $a < d < b$ and $b < e < c$ with $f'(d) = 0$ and $f'(e) = 0$. By Rolle's Theorem applied to $f'(x)$ on $[d, e]$ there is a number g with $d < g < e$ such that $f''(g) = 0$.
- (c) Suppose that f is n times differentiable on $\mathbb{R}$ and has $n + 1$ distinct real roots. Then $f^{(n)}$ has at least one real root.
23. By the Mean Value Theorem, $f(4) - f(1) = f'(c)(4 - 1)$ for some $c \in (1, 4)$. But for every $c \in (1, 4)$ we have $f'(c) \geq 2$. Putting $f'(c) \geq 2$ into the above equation and substituting $f(1) = 10$, we get $f(4) = f(1) + f'(c)(4 - 1) = 10 + 3f'(c) \geq 10 + 3 \cdot 2 = 16$. So the smallest possible value of $f(4)$ is 16.
24. If $3 \leq f'(x) \leq 5$ for all x , then by the Mean Value Theorem, $f(8) - f(2) = f'(c) \cdot (8 - 2)$ for some c in $[2, 8]$. (f is differentiable for all x , so, in particular, f is differentiable on $(2, 8)$ and continuous on $[2, 8]$. Thus, the hypotheses of the Mean Value Theorem are satisfied.) Since $f(8) - f(2) = 6f'(c)$ and $3 \leq f'(c) \leq 5$, it follows that $6 \cdot 3 \leq 6f'(c) \leq 6 \cdot 5 \Rightarrow 18 \leq f(8) - f(2) \leq 30$.
25. Suppose that such a function f exists. By the Mean Value Theorem there is a number $0 < c < 2$ with $f'(c) = \frac{f(2) - f(0)}{2 - 0} = \frac{5}{2}$. But this is impossible since $f'(x) \leq 2 < \frac{5}{2}$ for all x , so no such function can exist.
26. Let $h = f - g$. Then since f and g are continuous on $[a, b]$ and differentiable on (a, b) , so is h , and thus h satisfies the assumptions of the Mean Value Theorem. Therefore, there is a number c with $a < c < b$ such that $h(b) - h(a) = h'(c)(b - a)$. Since $h'(c) < 0$, $h'(c)(b - a) < 0$, so $f(b) - g(b) = h(b) < 0$ and hence $f(b) < g(b)$.
27. We use Exercise 26 with $f(x) = \sqrt{1+x}$, $g(x) = 1 + \frac{1}{2}x$, and $a = 0$. Notice that $f(0) = 1 = g(0)$ and $f'(x) = \frac{1}{2\sqrt{1+x}} < \frac{1}{2} = g'(x)$ for $x > 0$. So by Exercise 26, $f(b) < g(b) \Rightarrow \sqrt{1+b} < 1 + \frac{1}{2}b$ for $b > 0$.
Another method: Apply the Mean Value Theorem directly to either $f(x) = 1 + \frac{1}{2}x - \sqrt{1+x}$ or $g(x) = \sqrt{1+x}$ on $[0, b]$.
28. f satisfies the conditions for the Mean Value Theorem, so we use this theorem on the interval $[-b, b]$: $\frac{f(b) - f(-b)}{b - (-b)} = f'(c)$ for some $c \in (-b, b)$. But since f is odd, $f(-b) = -f(b)$. Substituting this into the above equation, we get $\frac{f(b) + f(b)}{2b} = f'(c) \Rightarrow \frac{f(b)}{b} = f'(c)$.

29. Let $f(x) = \sin x$ and let $b < a$. Then $f(x)$ is continuous on $[b, a]$ and differentiable on (b, a) . By the Mean Value Theorem, there is a number $c \in (b, a)$ with $\sin a - \sin b = f(a) - f(b) = f'(c)(a - b) = (\cos c)(a - b)$. Thus, $|\sin a - \sin b| \leq |\cos c| |b - a| \leq |a - b|$. If $a < b$, then $|\sin a - \sin b| = |\sin b - \sin a| \leq |b - a| = |a - b|$. If $a = b$, both sides of the inequality are 0.
30. Suppose that $f'(x) = c$. Let $g(x) = cx$, so $g'(x) = c$. Then, by Corollary 7, $f(x) = g(x) + d$, where d is a constant, so $f(x) = cx + d$.
31. For $x > 0$, $f(x) = g(x)$, so $f'(x) = g'(x)$. For $x < 0$, $f'(x) = (1/x)' = -1/x^2$ and $g'(x) = (1 + 1/x)' = -1/x^2$, so again $f'(x) = g'(x)$. However, the domain of $g(x)$ is not an interval [it is $(-\infty, 0) \cup (0, \infty)$] so we cannot conclude that $f - g$ is constant (in fact it is not).
32. Let $v(t)$ be the velocity of the car t hours after 2:00 P.M. Then $\frac{v(1/6) - v(0)}{1/6 - 0} = \frac{50 - 30}{1/6} = 120$. By the Mean Value Theorem, there is a number c such that $0 < c < \frac{1}{6}$ with $v'(c) = 120$. Since $v'(t)$ is the acceleration at time t , the acceleration c hours after 2:00 P.M. is exactly 120 mi/h².
33. Let $g(t)$ and $h(t)$ be the position functions of the two runners and let $f(t) = g(t) - h(t)$. By hypothesis, $f(0) = g(0) - h(0) = 0$ and $f(b) = g(b) - h(b) = 0$, where b is the finishing time. Then by the Mean Value Theorem, there is a time c , with $0 < c < b$, such that $f'(c) = \frac{f(b) - f(0)}{b - 0}$. But $f(b) = f(0) = 0$, so $f'(c) = 0$. Since $f'(c) = g'(c) - h'(c) = 0$, we have $g'(c) = h'(c)$. So at time c , both runners have the same speed $g'(c) = h'(c)$.
34. Assume that f is differentiable (and hence continuous) on $\mathbb{R}$ and that $f'(x) \neq 1$ for all x . Suppose f has more than one fixed point. Then there are numbers a and b such that $a < b$, $f(a) = a$, and $f(b) = b$. Applying the Mean Value Theorem to the function f on $[a, b]$, we find that there is a number c in (a, b) such that $f'(c) = \frac{f(b) - f(a)}{b - a}$. But then $f'(c) = \frac{b - a}{b - a} = 1$, contradicting our assumption that $f'(x) \neq 1$ for every real number x . This shows that our supposition was wrong, that is, that f cannot have more than one fixed point.

4.3 How Derivatives Affect the Shape of a Graph

- f is increasing on $(0, 6)$ and $(8, 9)$.
 - f is decreasing on $(6, 8)$.
 - f is concave upward on $(2, 4)$ and $(7, 9)$.
 - f is concave downward on $(0, 2)$ and $(4, 7)$.
 - The points of inflection are $(2, 3)$, $(4, 4.5)$ and $(7, 4)$ (where the concavity changes).
- f is increasing on $(1, \approx 3.8)$ and $(5, \approx 6.5)$.
 - f is decreasing on $(0, 1)$, $(\approx 3.8, 5)$, $(\approx 6.5, 8)$, and $(8, 9)$.
 - f is concave upward on $(0, 3)$ and $(8, 9)$.
 - f is concave downward on $(3, 5)$ and $(5, 8)$.
 - The point of inflection is $(3, \approx 1.8)$ (where the concavity changes).

3. (a) Use the Increasing/Decreasing (I/D) Test.
 (b) Use the Concavity Test.
 (c) At any value of x where the concavity changes, we have an inflection point at $(x, f(x))$.
4. (a) See the First Derivative Test.
 (b) See the Second Derivative Test and the note that precedes Example 7.
5. (a) Since $f'(x) > 0$ on $(1, 5)$, f is increasing on this interval. Since $f'(x) < 0$ on $(0, 1)$ and $(5, 6)$, f is decreasing on these intervals.
 (b) Since $f'(x) = 0$ at $x = 1$ and f' changes from negative to positive there, f changes from decreasing to increasing and has a local minimum at $x = 1$. Since $f'(x) = 0$ at $x = 5$ and f' changes from positive to negative there, f changes from increasing to decreasing and has a local maximum at $x = 5$.
6. (a) $f'(x) > 0$ and f is increasing on $(0, 1)$ and $(3, 5)$. $f'(x) < 0$ and f is decreasing on $(1, 3)$ and $(5, 6)$.
 (b) Since $f'(x) = 0$ at $x = 1$ and $x = 5$ and f' changes from positive to negative at both values, f changes from increasing to decreasing and has local maxima at $x = 1$ and $x = 5$. Since $f'(x) = 0$ at $x = 3$ and f' changes from negative to positive there, f changes from decreasing to increasing and has a local minimum at $x = 3$.
7. There is an inflection point at $x = 1$ because $f''(x)$ changes from negative to positive there, and so the graph of f changes from concave downward to concave upward. There is an inflection point at $x = 7$ because $f''(x)$ changes from positive to negative there, and so the graph of f changes from concave upward to concave downward.
8. (a) f is increasing on the intervals where $f'(x) > 0$, namely, $(2, 4)$ and $(6, 9)$.
 (b) f has a local maximum where it changes from increasing to decreasing, that is, where f' changes from positive to negative (at $x = 4$). Similarly, where f' changes from negative to positive, f has a local minimum (at $x = 2$ and at $x = 6$).
 (c) When f' is increasing, its derivative f'' is positive and hence, f is concave upward. This happens on $(1, 3)$, $(5, 7)$, and $(8, 9)$. Similarly, f is concave downward when f' is decreasing—that is, on $(0, 1)$, $(3, 5)$, and $(7, 8)$.
 (d) f has inflection points at $x = 1, 3, 5, 7$, and 8 , since the direction of concavity changes at each of these values.
9. The function must be always decreasing and concave downward.

10. (a) The rate of increase of the population is initially very small, then gets larger until it reaches a maximum at about $t = 8$ hours, and decreases toward 0 as the population begins to level off.
 (b) The rate of increase has its maximum value at $t = 8$ hours.
 (c) The population function is concave upward on $(0, 8)$ and concave downward on $(8, 18)$.
 (d) At $t = 8$, the population is about 350, so the inflection point is about $(8, 350)$.

11. (a) $f(x) = x^3 - 12x + 1 \Rightarrow f'(x) = 3x^2 - 12 = 3(x+2)(x-2)$.

We don't need to include "3" in the chart to determine the sign of $f'(x)$.

Interval	$x+2$	$x-2$	$f'(x)$	f
$x < -2$	-	-	+	increasing on $(-\infty, -2)$
$-2 < x < 2$	+	-	-	decreasing on $(-2, 2)$
$x > 2$	+	+	+	increasing on $(2, \infty)$

So f is increasing on $(-\infty, -2)$ and $(2, \infty)$ and f is decreasing on $(-2, 2)$.

(b) f changes from increasing to decreasing at $x = -2$ and from decreasing to increasing at $x = 2$. Thus, $f(-2) = 17$ is a local maximum value and $f(2) = -15$ is a local minimum value.

(c) $f''(x) = 6x$. $f''(x) > 0 \Leftrightarrow x > 0$ and $f''(x) < 0 \Leftrightarrow x < 0$. Thus, f is concave upward on $(0, \infty)$ and concave downward on $(-\infty, 0)$. There is an inflection point where the concavity changes, at $(0, f(0)) = (0, 1)$.

12. (a) $f(x) = 5 - 3x^2 + x^3 \Rightarrow f'(x) = -6x + 3x^2 = 3x(x-2)$. Thus, $f'(x) > 0 \Leftrightarrow x < 0$ or $x > 2$ and $f'(x) < 0 \Leftrightarrow 0 < x < 2$. So f is increasing on $(-\infty, 0)$ and $(2, \infty)$ and f is decreasing on $(0, 2)$.

(b) f changes from increasing to decreasing at $x = 0$ and from decreasing to increasing at $x = 2$. Thus, $f(0) = 5$ is a local maximum value and $f(2) = 1$ is a local minimum value.

(c) $f''(x) = -6 + 6x = 6(x-1)$. $f''(x) > 0 \Leftrightarrow x > 1$ and $f''(x) < 0 \Leftrightarrow x < 1$. Thus, f is concave upward on $(1, \infty)$ and concave downward on $(-\infty, 1)$. There is an inflection point at $(1, 3)$.

13. (a) $f(x) = x^4 - 2x^2 + 3 \Rightarrow f'(x) = 4x^3 - 4x = 4x(x^2 - 1) = 4x(x+1)(x-1)$.

Interval	$x+1$	x	$x-1$	$f'(x)$	f
$x < -1$	-	-	-	-	decreasing on $(-\infty, -1)$
$-1 < x < 0$	+	-	-	+	increasing on $(-1, 0)$
$0 < x < 1$	+	+	-	-	decreasing on $(0, 1)$
$x > 1$	+	+	+	+	increasing on $(1, \infty)$

So f is increasing on $(-1, 0)$ and $(1, \infty)$ and f is decreasing on $(-\infty, -1)$ and $(0, 1)$.

(b) f changes from increasing to decreasing at $x = 0$ and from decreasing to increasing at $x = -1$ and $x = 1$. Thus, $f(0) = 3$ is a local maximum value and $f(\pm 1) = 2$ are local minimum values.

(c) $f''(x) = 12x^2 - 4 = 12(x^2 - \frac{1}{3}) = 12(x + 1/\sqrt{3})(x - 1/\sqrt{3})$. $f''(x) > 0 \Leftrightarrow x < -1/\sqrt{3}$ or $x > 1/\sqrt{3}$ and $f''(x) < 0 \Leftrightarrow -1/\sqrt{3} < x < 1/\sqrt{3}$. Thus, f is concave upward on $(-\infty, -\sqrt{3}/3)$ and $(\sqrt{3}/3, \infty)$ and concave downward on $(-\sqrt{3}/3, \sqrt{3}/3)$. There are inflection points at $(\pm\sqrt{3}/3, \frac{22}{9})$.

14. (a) $f(x) = \frac{x^2}{x^2 + 3} \Rightarrow f'(x) = \frac{(x^2 + 3)(2x) - x^2(2x)}{(x^2 + 3)^2} = \frac{6x}{(x^2 + 3)^2}$. The denominator is positive so the sign

of $f'(x)$ is determined by the sign of x . Thus, $f'(x) > 0 \Leftrightarrow x > 0$ and $f'(x) < 0 \Leftrightarrow x < 0$. So f is increasing on $(0, \infty)$ and f is decreasing on $(-\infty, 0)$.

(b) f changes from decreasing to increasing at $x = 0$. Thus, $f(0) = 0$ is a local minimum value.

$$\begin{aligned} \text{(c) } f''(x) &= \frac{(x^2 + 3)^2(6) - 6x \cdot 2(x^2 + 3)(2x)}{[(x^2 + 3)^2]^2} = \frac{6(x^2 + 3)[x^2 + 3 - 4x^2]}{(x^2 + 3)^4} \\ &= \frac{6(3 - 3x^2)}{(x^2 + 3)^3} = \frac{-18(x + 1)(x - 1)}{(x^2 + 3)^3}. \end{aligned}$$

$f''(x) > 0 \Leftrightarrow -1 < x < 1$ and $f''(x) < 0 \Leftrightarrow x < -1$ or $x > 1$. Thus, f is concave upward on $(-1, 1)$ and concave downward on $(-\infty, -1)$ and $(1, \infty)$. There are inflection points at $(\pm 1, \frac{1}{4})$.

15. (a) $f(x) = x - 2 \sin x$ on $(0, 3\pi) \Rightarrow f'(x) = 1 - 2 \cos x$. $f'(x) > 0 \Leftrightarrow 1 - 2 \cos x > 0 \Leftrightarrow \cos x < \frac{1}{2}$
 $\Leftrightarrow \frac{\pi}{3} < x < \frac{5\pi}{3}$ or $\frac{7\pi}{3} < x < 3\pi$. $f'(x) < 0 \Leftrightarrow \cos x > \frac{1}{2} \Leftrightarrow 0 < x < \frac{\pi}{3}$ or $\frac{5\pi}{3} < x < \frac{7\pi}{3}$. So f is increasing on $(\frac{\pi}{3}, \frac{5\pi}{3})$ and $(\frac{7\pi}{3}, 3\pi)$, and f is decreasing on $(0, \frac{\pi}{3})$ and $(\frac{5\pi}{3}, \frac{7\pi}{3})$.

(b) f changes from increasing to decreasing at $x = \frac{5\pi}{3}$, and from decreasing to increasing at $x = \frac{\pi}{3}$ and at $x = \frac{7\pi}{3}$.
 Thus, $f(\frac{5\pi}{3}) = \frac{5\pi}{3} + \sqrt{3} \approx 6.97$ is a local maximum value and $f(\frac{\pi}{3}) = \frac{\pi}{3} - \sqrt{3} \approx -0.68$ and $f(\frac{7\pi}{3}) = \frac{7\pi}{3} - \sqrt{3} \approx 5.60$ are local minimum values.

(c) $f''(x) = 2 \sin x > 0 \Leftrightarrow 0 < x < \pi$ and $2\pi < x < 3\pi$, $f''(x) < 0 \Leftrightarrow \pi < x < 2\pi$. Thus, f is concave upward on $(0, \pi)$ and $(2\pi, 3\pi)$, and f is concave downward on $(\pi, 2\pi)$. There are inflection points at (π, π) and $(2\pi, 2\pi)$.

16. (a) $f(x) = \cos^2 x - 2 \sin x$, $0 \leq x \leq 2\pi$. $f'(x) = -2 \cos x \sin x - 2 \cos x = -2 \cos x (1 + \sin x)$. Note that $1 + \sin x \geq 0$ [since $\sin x \geq -1$], with equality $\Leftrightarrow \sin x = -1 \Leftrightarrow x = 3\pi/2$ [since $0 \leq x \leq 2\pi$]
 $\Rightarrow \cos x = 0$. Thus, $f'(x) > 0 \Leftrightarrow \cos x < 0 \Leftrightarrow \pi/2 < x < 3\pi/2$ and $f'(x) < 0 \Leftrightarrow \cos x > 0$
 $\Leftrightarrow 0 < x < \pi/2$ or $3\pi/2 < x < 2\pi$. Thus, f is increasing on $(\pi/2, 3\pi/2)$ and f is decreasing on $(0, \pi/2)$ and $(3\pi/2, 2\pi)$.

(b) f changes from decreasing to increasing at $x = \pi/2$ and from increasing to decreasing at $x = 3\pi/2$. Thus, $f(\pi/2) = -2$ is a local minimum value and $f(3\pi/2) = 2$ is a local maximum value.

(c) $f''(x) = 2 \sin x (1 + \sin x) - 2 \cos^2 x = 2 \sin x + 2 \sin^2 x - 2(1 - \sin^2 x)$
 $= 4 \sin^2 x + 2 \sin x - 2 = 2(2 \sin x - 1)(\sin x + 1)$
 so $f''(x) > 0 \Leftrightarrow \sin x > \frac{1}{2} \Leftrightarrow \frac{\pi}{6} < x < \frac{5\pi}{6}$, and $f''(x) < 0 \Leftrightarrow \sin x < \frac{1}{2}$ and $\sin x \neq -1 \Leftrightarrow$
 $0 < x < \frac{\pi}{6}$ or $\frac{5\pi}{6} < x < \frac{3\pi}{2}$ or $\frac{3\pi}{2} < x < 2\pi$. Thus, f is concave upward on $(\frac{\pi}{6}, \frac{5\pi}{6})$ and concave downward on $(0, \frac{\pi}{6})$, $(\frac{5\pi}{6}, \frac{3\pi}{2})$, and $(\frac{3\pi}{2}, 2\pi)$. There are inflection points at $(\frac{\pi}{6}, -\frac{1}{4})$ and $(\frac{5\pi}{6}, -\frac{1}{4})$.

17. $f(x) = x^5 - 5x + 3 \Rightarrow f'(x) = 5x^4 - 5 = 5(x^2 + 1)(x + 1)(x - 1)$.

First Derivative Test: $f'(x) < 0 \Rightarrow -1 < x < 1$ and $f'(x) > 0 \Rightarrow x > 1$ or $x < -1$. Since f' changes from positive to negative at $x = -1$, $f(-1) = 7$ is a local maximum value; and since f' changes from negative to positive at $x = 1$, $f(1) = -1$ is a local minimum value.

Second Derivative Test: $f''(x) = 20x^3$. $f'(x) = 0 \Leftrightarrow x = \pm 1$. $f''(-1) = -20 < 0 \Rightarrow f(-1) = 7$ is a local maximum value. $f''(1) = 20 > 0 \Rightarrow f(1) = -1$ is a local minimum value.

Preference: For this function, the two tests are equally easy.

$$18. f(x) = \frac{x}{x^2 + 4} \Rightarrow f'(x) = \frac{(x^2 + 4) \cdot 1 - x(2x)}{(x^2 + 4)^2} = \frac{4 - x^2}{(x^2 + 4)^2} = \frac{(2 + x)(2 - x)}{(x^2 + 4)^2}.$$

First Derivative Test: $f'(x) > 0 \Rightarrow -2 < x < 2$ and $f'(x) < 0 \Rightarrow x > 2$ or $x < -2$. Since f' changes from positive to negative at $x = 2$, $f(2) = \frac{1}{4}$ is a local maximum value; and since f' changes from negative to positive at $x = -2$, $f(-2) = -\frac{1}{4}$ is a local minimum value.

Second Derivative Test:

$$\begin{aligned} f''(x) &= \frac{(x^2 + 4)^2(-2x) - (4 - x^2) \cdot 2(x^2 + 4)(2x)}{[(x^2 + 4)^2]^2} \\ &= \frac{-2x(x^2 + 4)[(x^2 + 4) + 2(4 - x^2)]}{(x^2 + 4)^4} = \frac{-2x(12 - x^2)}{(x^2 + 4)^3} \end{aligned}$$

$f'(x) = 0 \Leftrightarrow x = \pm 2$. $f''(-2) = \frac{1}{16} > 0 \Rightarrow f(-2) = -\frac{1}{4}$ is a local minimum value.

$f''(2) = -\frac{1}{16} < 0 \Rightarrow f(2) = \frac{1}{4}$ is a local maximum value.

Preference: Since calculating the second derivative is fairly difficult, the First Derivative Test is easier to use for this function.

19. $f(x) = x + \sqrt{1-x} \Rightarrow f'(x) = 1 + \frac{1}{2}(1-x)^{-1/2}(-1) = 1 - \frac{1}{2\sqrt{1-x}}$. Note that f is defined for $1-x \geq 0$; that is, for $x \leq 1$. $f'(x) = 0 \Rightarrow 2\sqrt{1-x} = 1 \Rightarrow \sqrt{1-x} = \frac{1}{2} \Rightarrow 1-x = \frac{1}{4} \Rightarrow x = \frac{3}{4}$. f' does not exist at $x = 1$, but we can't have a local maximum or minimum at an endpoint.

First Derivative Test: $f'(x) > 0 \Rightarrow x < \frac{3}{4}$ and $f'(x) < 0 \Rightarrow \frac{3}{4} < x < 1$. Since f' changes from positive to negative at $x = \frac{3}{4}$, $f(\frac{3}{4}) = \frac{5}{4}$ is a local maximum value.

Second Derivative Test: $f''(x) = -\frac{1}{2}(-\frac{1}{2})(1-x)^{-3/2}(-1) = -\frac{1}{4(\sqrt{1-x})^3}$. $f''(\frac{3}{4}) = -2 < 0 \Rightarrow$

$f(\frac{3}{4}) = \frac{5}{4}$ is a local maximum value.

Preference: The First Derivative Test may be slightly easier to apply in this case.

20. (a) $f(x) = x^4(x-1)^3 \Rightarrow$
 $f'(x) = x^4 \cdot 3(x-1)^2 + (x-1)^3 \cdot 4x^3 = x^3(x-1)^2[3x + 4(x-1)] = x^3(x-1)^2(7x-4)$
 The critical numbers are 0, 1, and $\frac{4}{7}$.
 (b) $f''(x) = 3x^2(x-1)^2(7x-4) + x^3 \cdot 2(x-1)(7x-4) + x^3(x-1)^2 \cdot 7$
 $= x^2(x-1)[3(x-1)(7x-4) + 2x(7x-4) + 7x(x-1)]$
 Now $f''(0) = f''(1) = 0$, so the Second Derivative Test gives no information for $x = 0$ or $x = 1$.
 $f''(\frac{4}{7}) = (\frac{4}{7})^2(\frac{4}{7}-1)[0 + 0 + 7(\frac{4}{7})(\frac{4}{7}-1)] = (\frac{4}{7})^2(-\frac{3}{7})(4)(-\frac{3}{7}) > 0$, so there is a local minimum at $x = \frac{4}{7}$.
 (c) f' is positive on $(-\infty, 0)$, negative on $(0, \frac{4}{7})$, positive on $(\frac{4}{7}, 1)$, and positive on $(1, \infty)$. So f has a local maximum at $x = 0$, a local minimum at $x = \frac{4}{7}$, and no local maximum or minimum at $x = 1$.
 21. (a) By the Second Derivative Test, if $f'(2) = 0$ and $f''(2) = -5 < 0$, f has a local maximum at $x = 2$.
 (b) If $f'(6) = 0$, we know that f has a horizontal tangent at $x = 6$. Knowing that $f''(6) = 0$ does not provide any additional information since the Second Derivative Test fails. For example, the first and second derivatives of $y = (x-6)^4$, $y = -(x-6)^4$, and $y = (x-6)^3$ all equal zero for $x = 6$, but the first has a local minimum at $x = 6$, the second has a local maximum at $x = 6$, and the third has an inflection point at $x = 6$.

22. $f'(x) > 0$ for all $x \neq 1$ with vertical asymptote $x = 1$, so f is increasing on $(-\infty, 1)$ and $(1, \infty)$. $f''(x) > 0$ if $x < 1$ or $x > 3$, and $f''(x) < 0$ if $1 < x < 3$, so f is concave upward on $(-\infty, 1)$ and $(3, \infty)$, and concave downward on $(1, 3)$. There is an inflection point when $x = 3$.

23. $f'(0) = f'(2) = f'(4) = 0 \Rightarrow$ horizontal tangents at $x = 0, 2, 4$.
 $f'(x) > 0$ if $x < 0$ or $2 < x < 4 \Rightarrow f$ is increasing on $(-\infty, 0)$
 and $(2, 4)$. $f'(x) < 0$ if $0 < x < 2$ or $x > 4 \Rightarrow f$ is decreasing
 on $(0, 2)$ and $(4, \infty)$. $f''(x) > 0$ if $1 < x < 3 \Rightarrow f$ is concave
 upward on $(1, 3)$. $f''(x) < 0$ if $x < 1$ or $x > 3 \Rightarrow f$ is concave
 downward on $(-\infty, 1)$ and $(3, \infty)$. There are inflection points when
 $x = 1$ and 3 .

24.

$f'(1) = f'(-1) = 0 \Rightarrow$ horizontal tangents at $x = \pm 1$.
 $f'(x) < 0$ if $|x| < 1 \Rightarrow f$ is decreasing on $(-1, 1)$. $f'(x) > 0$ if
 $1 < |x| < 2 \Rightarrow f$ is increasing on $(-2, -1)$ and $(1, 2)$.
 $f'(x) = -1$ if $|x| > 2 \Rightarrow$ the graph of f has constant slope -1
 on $(-\infty, -2)$ and $(2, \infty)$. $f''(x) < 0$ if $-2 < x < 0 \Rightarrow$
 f is concave downward on $(-2, 0)$. Inflection point $(0, 1)$.

25. $f'(x) > 0$ if $|x| < 2 \Rightarrow f$ is increasing on $(-2, 2)$. $f'(x) < 0$ if $|x| > 2 \Rightarrow f$ is decreasing on $(-\infty, -2)$
 and $(2, \infty)$. $f'(-2) = 0 \Rightarrow$ horizontal tangent at $x = -2$. $\lim_{x \rightarrow 2} |f'(x)| = \infty \Rightarrow$ there is a vertical asymp-
 tote or vertical tangent (cusp) at $x = 2$. $f''(x) > 0$ if $x \neq 2 \Rightarrow f$ is concave upward on $(-\infty, 2)$ and $(2, \infty)$.

26.

$f(0) = f'(0) = 0 \Rightarrow$ the graph of f passes through the origin
 and has a horizontal tangent there. $f'(2) = f'(4) = f'(6) = 0 \Rightarrow$
 horizontal tangents at $x = 2, 4, 6$. $f'(x) > 0$ if $0 < x < 2$ or
 $4 < x < 6 \Rightarrow f$ increasing on $(0, 2)$ and $(4, 6)$. $f'(x) < 0$ if
 $2 < x < 4$ or $x > 6 \Rightarrow f$ decreasing on $(2, 4)$ and $(6, \infty)$.

$f''(x) > 0$ if $0 < x < 1$ or $3 < x < 5 \Rightarrow f$ is CU on $(0, 1)$

and $(3, 5)$. $f''(x) < 0$ if $1 < x < 3$ or $x > 5 \Rightarrow f$ is CD on $(1, 3)$ and $(5, \infty)$. $f(-x) = f(x) \Rightarrow f$ is
 even and the graph is symmetric about the y -axis.

27. (a) f is increasing where f' is positive, that is, on $(0, 2)$, $(4, 6)$, and $(8, \infty)$; and decreasing where f' is negative,
 that is, on $(2, 4)$ and $(6, 8)$.
 (b) f has local maxima where f' changes from positive to negative, at $x = 2$ and at $x = 6$, and local minima where
 f' changes from negative to positive, at $x = 4$ and at $x = 8$.
 (c) f is concave upward (CU) where f' is increasing, that is, on $(3, 6)$
 and $(6, \infty)$, and concave downward (CD) where f' is decreasing, that
 is, on $(0, 3)$.
 (d) There is a point of inflection where f changes from being CD to
 being CU, that is, at $x = 3$.

28. (a) f is increasing where f' is positive, on $(1, 6)$ and $(8, \infty)$, and decreasing where f' is negative, on $(0, 1)$ and $(6, 8)$.

(b) f has a local maximum where f' changes from positive to negative, at $x = 6$, and local minima where f' changes from negative to positive, at $x = 1$ and at $x = 8$.

(c) f is concave upward where f' is increasing, that is, on $(0, 2)$, $(3, 5)$, and $(7, \infty)$, and concave downward where f' is decreasing, that is, on $(2, 3)$ and $(5, 7)$.

(d) There are points of inflection where f changes its direction of concavity, at $x = 2$, $x = 3$, $x = 5$ and $x = 7$.

29. (a) $f(x) = 2x^3 - 3x^2 - 12x \Rightarrow f'(x) = 6x^2 - 6x - 12 = 6(x^2 - x - 2) = 6(x - 2)(x + 1)$. $f'(x) > 0 \Leftrightarrow x < -1$ or $x > 2$ and $f'(x) < 0 \Leftrightarrow -1 < x < 2$. So f is increasing on $(-\infty, -1)$ and $(2, \infty)$, and f is decreasing on $(-1, 2)$.

(b) Since f changes from increasing to decreasing at $x = -1$, $f(-1) = 7$ is a local maximum value. Since f changes from decreasing to increasing at $x = 2$, $f(2) = -20$ is a local minimum value.

(c) $f''(x) = 6(2x - 1) \Rightarrow f''(x) > 0$ on $(\frac{1}{2}, \infty)$ and $f''(x) < 0$ on $(-\infty, \frac{1}{2})$. So f is concave upward on $(\frac{1}{2}, \infty)$ and concave downward on $(-\infty, \frac{1}{2})$. There is a change in concavity at $x = \frac{1}{2}$, and we have an inflection point at $(\frac{1}{2}, -\frac{13}{2})$.

30. (a) $f(x) = 2 + 3x - x^3 \Rightarrow f'(x) = 3 - 3x^2 = -3(x^2 - 1) = -3(x + 1)(x - 1)$. $f'(x) > 0 \Leftrightarrow -1 < x < 1$ and $f'(x) < 0 \Leftrightarrow x < -1$ or $x > 1$. So f is increasing on $(-1, 1)$ and f is decreasing on $(-\infty, -1)$ and $(1, \infty)$.

(b) $f(-1) = 0$ is a local minimum value and $f(1) = 4$ is a local maximum value.

(c) $f''(x) = -6x \Rightarrow f''(x) > 0$ on $(-\infty, 0)$ and $f''(x) < 0$ on $(0, \infty)$. So f is concave upward on $(-\infty, 0)$ and concave downward on $(0, \infty)$. There is an inflection point at $(0, 2)$.

31. (a) $f(x) = x^4 - 6x^2 \Rightarrow f'(x) = 4x^3 - 12x = 4x(x^2 - 3) = 0$ when $x = 0, \pm\sqrt{3}$.

Interval	$4x$	$x^2 - 3$	$f'(x)$	f
$x < -\sqrt{3}$	-	+	-	decreasing on $(-\infty, -\sqrt{3})$
$-\sqrt{3} < x < 0$	-	-	+	increasing on $(-\sqrt{3}, 0)$
$0 < x < \sqrt{3}$	+	-	-	decreasing on $(0, \sqrt{3})$
$x > \sqrt{3}$	+	+	+	increasing on $(\sqrt{3}, \infty)$

(b) Local minimum values $f(\pm\sqrt{3}) = -9$,

local maximum value $f(0) = 0$

(c) $f''(x) = 12x^2 - 12 = 12(x^2 - 1) > 0 \Leftrightarrow x^2 > 1 \Leftrightarrow$

$|x| > 1 \Leftrightarrow x > 1 \text{ or } x < -1$, so f is CU on $(-\infty, -1)$, $(1, \infty)$

and CD on $(-1, 1)$. Inflection points at $(\pm 1, -5)$

32. (a) $g(x) = 200 + 8x^3 + x^4 \Rightarrow g'(x) = 24x^2 + 4x^3 = 4x^2(6 + x) = 0$ when $x = -6$ and when $x = 0$.

$g'(x) > 0 \Leftrightarrow x > -6$ ($x \neq 0$) and $g'(x) < 0 \Leftrightarrow x < -6$, so g is decreasing on $(-\infty, -6)$ and g is increasing on $(-6, \infty)$, with a horizontal tangent at $x = 0$.

(b) $g(-6) = -232$ is a local minimum value.

There is no local maximum value.

(c) $g''(x) = 48x + 12x^2 = 12x(4 + x) = 0$ when $x = -4$ and when

$x = 0$. $g''(x) > 0 \Leftrightarrow x < -4$ or $x > 0$ and $g''(x) < 0 \Leftrightarrow$

$-4 < x < 0$, so g is CU on $(-\infty, -4)$ and $(0, \infty)$, and g is CD on

$(-4, 0)$. Inflection points at $(-4, -56)$ and $(0, 200)$

33. (a) $h(x) = 3x^5 - 5x^3 + 3 \Rightarrow h'(x) = 15x^4 - 15x^2 = 15x^2(x^2 - 1) = 0$ when $x = 0, \pm 1$. Since $15x^2$ is

nonnegative, $h'(x) > 0 \Leftrightarrow x^2 > 1 \Leftrightarrow |x| > 1 \Leftrightarrow x > 1 \text{ or } x < -1$, so h is increasing on

$(-\infty, -1)$ and $(1, \infty)$ and decreasing on $(-1, 1)$, with a horizontal tangent at $x = 0$.

(b) Local maximum value $h(-1) = 5$, local minimum value $h(1) = 1$

(c) $h''(x) = 60x^3 - 30x = 30x(2x^2 - 1)$

$$= 60x\left(x + \frac{1}{\sqrt{2}}\right)\left(x - \frac{1}{\sqrt{2}}\right) \Rightarrow$$

$h''(x) > 0$ when $x > \frac{1}{\sqrt{2}}$ or $-\frac{1}{\sqrt{2}} < x < 0$, so h is CU on

$(-\frac{1}{\sqrt{2}}, 0)$ and $(\frac{1}{\sqrt{2}}, \infty)$ and CD on $(-\infty, -\frac{1}{\sqrt{2}})$ and $(0, \frac{1}{\sqrt{2}})$.

Inflection points at $(0, 3)$ and $(\pm \frac{1}{\sqrt{2}}, 3 \mp \frac{7}{8}\sqrt{2})$ [about

$(-0.71, 4.24)$ and $(0.71, 1.76)$].

34. (a) $h(x) = (x^2 - 1)^3 \Rightarrow h'(x) = 6x(x^2 - 1)^2 \geq 0 \Leftrightarrow x > 0$ ($x \neq 1$), so h is increasing on $(0, \infty)$ and

decreasing on $(-\infty, 0)$.

(b) $h(0) = -1$ is a local minimum value.

(c) $h''(x) = 6(x^2 - 1)^2 + 24x^2(x^2 - 1) = 6(x^2 - 1)(5x^2 - 1)$. The roots ± 1 and $\pm \frac{1}{\sqrt{5}}$ divide $\mathbb{R}$ into five intervals.

Interval	$x^2 - 1$	$5x^2 - 1$	$h''(x)$	Concavity
$x < -1$	+	+	+	upward
$-1 < x < -\frac{1}{\sqrt{5}}$	-	+	-	downward
$-\frac{1}{\sqrt{5}} < x < \frac{1}{\sqrt{5}}$	-	-	+	upward
$\frac{1}{\sqrt{5}} < x < 1$	-	+	-	downward
$x > 1$	+	+	+	upward

From the table, we see that h is CU on $(-\infty, -1)$,

$(-\frac{1}{\sqrt{5}}, \frac{1}{\sqrt{5}})$ and $(1, \infty)$, and CD on $(-1, -\frac{1}{\sqrt{5}})$ and $(\frac{1}{\sqrt{5}}, 1)$.

Inflection points at $(\pm 1, 0)$ and $(\pm \frac{1}{\sqrt{5}}, -\frac{64}{125})$

35. (a) $A(x) = x\sqrt{x+3} \Rightarrow$

$$A'(x) = x \cdot \frac{1}{2}(x+3)^{-1/2} + \sqrt{x+3} \cdot 1 = \frac{x}{2\sqrt{x+3}} + \sqrt{x+3} = \frac{x+2(x+3)}{2\sqrt{x+3}} = \frac{3x+6}{2\sqrt{x+3}}.$$

The domain of A is $[-3, \infty)$. $A'(x) > 0$ for $x > -2$ and $A'(x) < 0$ for $-3 < x < -2$, so A is increasing on $(-2, \infty)$ and decreasing on $(-3, -2)$.

(b) $A(-2) = -2$ is a local minimum value.

$$\begin{aligned} \text{(c) } A''(x) &= \frac{2\sqrt{x+3} \cdot 3 - (3x+6) \cdot \frac{1}{\sqrt{x+3}}}{(2\sqrt{x+3})^2} \\ &= \frac{6(x+3) - (3x+6)}{4(x+3)^{3/2}} = \frac{3x+12}{4(x+3)^{3/2}} = \frac{3(x+4)}{4(x+3)^{3/2}} \end{aligned}$$

$A''(x) > 0$ for all $x > -3$, so A is concave upward on $(-3, \infty)$.

There is no inflection point.

36. (a) $G(x) = x - 4\sqrt{x} \Rightarrow G'(x) = 1 - \frac{2}{\sqrt{x}} = \frac{1}{\sqrt{x}}(\sqrt{x} - 2)$. $G'(x) > 0 \Leftrightarrow x > 4$ and $G'(x) < 0 \Leftrightarrow 0 < x < 4$, so G is decreasing on $(0, 4)$ and increasing on $(4, \infty)$.

(b) Local minimum $G(4) = -4$. No local maximum.

(c) $G'(x) = 1 - 2x^{-1/2} \Rightarrow G''(x) = x^{-3/2} = 1/\sqrt{x^3}$, so

$G''(x) > 0$ for $x > 0$. Thus, G is CU on $(0, \infty)$.

G has no IPs.

$$37. (a) C(x) = x^{1/3}(x+4) = x^{4/3} + 4x^{1/3} \Rightarrow C'(x) = \frac{4}{3}x^{1/3} + \frac{4}{3}x^{-2/3} = \frac{4}{3}x^{-2/3}(x+1) = \frac{4(x+1)}{3\sqrt[3]{x^2}}.$$

$C'(x) > 0$ if $-1 < x < 0$ or $x > 0$ and $C'(x) < 0$ for $x < -1$, so C is increasing on $(-1, \infty)$ and C is decreasing on $(-\infty, -1)$.

(b) $C(-1) = -3$ is a local minimum value.

$$(c) C''(x) = \frac{4}{9}x^{-2/3} - \frac{8}{9}x^{-5/3} = \frac{4}{9}x^{-5/3}(x-2) = \frac{4(x-2)}{9\sqrt[3]{x^5}}.$$

$C''(x) < 0$ for $0 < x < 2$ and $C''(x) > 0$ for $x < 0$ and $x > 2$, so

C is concave downward on $(0, 2)$ and concave upward on $(-\infty, 0)$

and $(2, \infty)$. There are inflection points at $(0, 0)$ and

$$(2, 6\sqrt[3]{2}) \approx (2, 7.56).$$

$$38. (a) B(x) = 3x^{2/3} - x \Rightarrow B'(x) = 2x^{-1/3} - 1 = \frac{2}{\sqrt[3]{x}} - 1 = \frac{2 - \sqrt[3]{x}}{\sqrt[3]{x}}. B'(x) > 0 \text{ if } 0 < x < 8 \text{ and}$$

$B'(x) < 0$ if $x < 0$ or $x > 8$, so B is decreasing on $(-\infty, 0)$ and $(8, \infty)$, and B is increasing on $(0, 8)$.

(b) $B(0) = 0$ is a local minimum value.

$B(8) = 4$ is a local maximum value.

$$(c) B''(x) = -\frac{2}{3}x^{-4/3} = \frac{-2}{3x^{4/3}}, \text{ so } B''(x) < 0 \text{ for all } x \neq 0. B \text{ is}$$

concave downward on $(-\infty, 0)$ and $(0, \infty)$. There is no inflection point.

$$39. (a) f(\theta) = 2 \cos \theta - \cos 2\theta, 0 \leq \theta \leq 2\pi.$$

$$f'(\theta) = -2 \sin \theta + 2 \sin 2\theta = -2 \sin \theta + 2(2 \sin \theta \cos \theta) = 2 \sin \theta (2 \cos \theta - 1).$$

Interval	$\sin \theta$	$2 \cos \theta - 1$	$f'(\theta)$	f
$0 < \theta < \frac{\pi}{3}$	+	+	+	increasing on $(0, \frac{\pi}{3})$
$\frac{\pi}{3} < \theta < \pi$	+	-	-	decreasing on $(\frac{\pi}{3}, \pi)$
$\pi < \theta < \frac{5\pi}{3}$	-	-	+	increasing on $(\pi, \frac{5\pi}{3})$
$\frac{5\pi}{3} < \theta < 2\pi$	-	+	-	decreasing on $(\frac{5\pi}{3}, 2\pi)$

(b) $f(\frac{\pi}{3}) = \frac{3}{2}$ and $f(\frac{5\pi}{3}) = \frac{3}{2}$ are local maximum values and $f(\pi) = -3$ is a local minimum value.

$$(c) f'(\theta) = -2 \sin \theta + 2 \sin 2\theta \Rightarrow$$

$$f''(\theta) = -2 \cos \theta + 4 \cos 2\theta = -2 \cos \theta + 4(2 \cos^2 \theta - 1) \\ = 2(4 \cos^2 \theta - \cos \theta - 2)$$

$$f''(\theta) = 0 \Leftrightarrow \cos \theta = \frac{1 \pm \sqrt{33}}{8} \Leftrightarrow \theta = \cos^{-1}\left(\frac{1 \pm \sqrt{33}}{8}\right)$$

$$\Leftrightarrow \theta = \cos^{-1}\left(\frac{1 + \sqrt{33}}{8}\right) \approx 0.5678,$$

$$2\pi - \cos^{-1}\left(\frac{1 + \sqrt{33}}{8}\right) \approx 5.7154, \cos^{-1}\left(\frac{1 - \sqrt{33}}{8}\right) \approx 2.2057, \text{ or } 2\pi - \cos^{-1}\left(\frac{1 - \sqrt{33}}{8}\right) \approx 4.0775.$$

Denote these four values of θ by $\theta_1, \theta_4, \theta_2$, and θ_3 , respectively. Then f is CU on $(0, \theta_1)$, CD on (θ_1, θ_2) ,

CU on (θ_2, θ_3) , CD on (θ_3, θ_4) , and CU on $(\theta_4, 2\pi)$. To find the *exact* y -coordinate for $\theta = \theta_1$, we have

$$\begin{aligned} f(\theta_1) &= 2 \cos \theta_1 - \cos 2\theta_1 = 2 \cos \theta_1 - (2 \cos^2 \theta_1 - 1) = 2 \left(\frac{1 + \sqrt{33}}{8} \right) - 2 \left(\frac{1 + \sqrt{33}}{8} \right)^2 + 1 \\ &= \frac{1}{4} + \frac{1}{4} \sqrt{33} - \frac{1}{32} - \frac{1}{16} \sqrt{33} - \frac{33}{32} + 1 = \frac{3}{16} + \frac{3}{16} \sqrt{33} = \frac{3}{16} (1 + \sqrt{33}) = y_1 \approx 1.26. \end{aligned}$$

Similarly, $f(\theta_2) = \frac{3}{16} (1 - \sqrt{33}) = y_2 \approx -0.89$. So f has inflection points at (θ_1, y_1) , (θ_2, y_2) , (θ_3, y_2) , and (θ_4, y_1) .

40. (a) $f(t) = t + \cos t, -2\pi \leq t \leq 2\pi \Rightarrow$

$$f'(t) = 1 - \sin t \geq 0 \text{ for all } t \text{ and } f'(t) = 0 \text{ when}$$

$$\sin t = 1 \Leftrightarrow t = -\frac{3\pi}{2} \text{ or } \frac{\pi}{2}, \text{ so } f \text{ is increasing}$$

$$\text{on } (-2\pi, 2\pi).$$

(b) No maximum or minimum

(c) $f''(t) = -\cos t > 0 \Leftrightarrow t \in (-\frac{3\pi}{2}, -\frac{\pi}{2}) \cup (\frac{\pi}{2}, \frac{3\pi}{2})$, so f is CU on these intervals and CD on $(-2\pi, -\frac{3\pi}{2})$, $(-\frac{\pi}{2}, \frac{\pi}{2})$, and $(\frac{3\pi}{2}, 2\pi)$. Points of inflection at $(\pm\frac{3\pi}{2}, \pm\frac{3\pi}{2})$ and $(\pm\frac{\pi}{2}, \pm\frac{\pi}{2})$

(d)

41. (a)

From the graph, we get an estimate of $f(1) \approx 1.41$ as a local maximum value, and no local minimum value.

$$f(x) = \frac{x+1}{\sqrt{x^2+1}} \Rightarrow f'(x) = \frac{1-x}{(x^2+1)^{3/2}}$$

$$f'(x) = 0 \Leftrightarrow x = 1. f(1) = \frac{2}{\sqrt{2}} = \sqrt{2} \text{ is the exact value.}$$

(b) From the graph in part (a), f increases most rapidly somewhere between $x = -\frac{1}{2}$ and $x = -\frac{1}{4}$. To find the exact value, we need to find the maximum value of f' , which we can do by finding the critical numbers of f' .

$$f''(x) = \frac{2x^2 - 3x - 1}{(x^2 + 1)^{5/2}} = 0 \Leftrightarrow x = \frac{3 \pm \sqrt{17}}{4}. x = \frac{3 + \sqrt{17}}{4} \text{ corresponds to the minimum value of } f'.$$

$$\text{The maximum value of } f' \text{ is at } \left(\frac{3 - \sqrt{17}}{4}, \sqrt{\frac{7}{6} - \frac{\sqrt{17}}{6}} \right) \approx (-0.28, 0.69).$$

42. (a)

From the graph, we get estimates of $f(2.61) \approx 0.89$ as a local and absolute minimum, $f(0.53) \approx 2.26$ as a local maximum, and $f(2\pi) \approx 8.28$ as an absolute maximum. $f(x) = x + 2 \cos x$

$$(0 \leq x \leq 2\pi) \Rightarrow f'(x) = 1 - 2 \sin x. f'(x) = 0 \Leftrightarrow$$

$$\sin x = \frac{1}{2} \Leftrightarrow x = \frac{\pi}{6}, \frac{5\pi}{6}. f\left(\frac{\pi}{6}\right) = \frac{\pi}{6} + \sqrt{3} \text{ is the exact value of the local maximum, } f\left(\frac{5\pi}{6}\right) = \frac{5\pi}{6} - \sqrt{3} \text{ is the exact value of the local}$$

and absolute minimum, and $f(2\pi) = 2\pi + 2$ is the exact value of the absolute maximum.

(b) From the graph in part (a), f increases most rapidly somewhere between $x = 4.5$ and $x = 5$. Now f increases most rapidly when $f'(x) = 1 - 2 \sin x$ has its maximum value. $f''(x) = -2 \cos x = 0 \Leftrightarrow x = \frac{\pi}{2}, \frac{3\pi}{2}$.

$$f'(0) = f'(2\pi) = 1, f'\left(\frac{\pi}{2}\right) = -1, \text{ and } f'\left(\frac{3\pi}{2}\right) = 3. \text{ The maximum value of } f' \text{ occurs at } \left(\frac{3\pi}{2}, \frac{3\pi}{2}\right).$$

43. $f(x) = \cos x + \frac{1}{2} \cos 2x \Rightarrow f'(x) = -\sin x - \sin 2x \Rightarrow f''(x) = -\cos x - 2 \cos 2x$

From the graph of f , it seems that f is CD on $(0, 1)$, CU on $(1, 2.5)$, CD on $(2.5, 3.7)$, CU on $(3.7, 5.3)$, and CD on $(5.3, 2\pi)$. The points of inflection appear to be at $(1, 0.4)$, $(2.5, -0.6)$, $(3.7, -0.6)$, and $(5.3, 0.4)$.

From the graph of f'' (and zooming in near the zeros), it seems that f is CD on $(0, 0.94)$, CU on $(0.94, 2.57)$, CD on $(2.57, 3.71)$, CU on $(3.71, 5.35)$, and CD on $(5.35, 2\pi)$. Refined estimates of the inflection points are $(0.94, 0.44)$, $(2.57, -0.63)$, $(3.71, -0.63)$, and $(5.35, 0.44)$.

44. $f(x) = x^3(x-2)^4 \Rightarrow$

$$f'(x) = x^3 \cdot 4(x-2)^3 + (x-2)^4 \cdot 3x^2 = x^2(x-2)^3[4x + 3(x-2)] = x^2(x-2)^3(7x-6) \Rightarrow$$

$$f''(x) = (2x)(x-2)^3(7x-6) + x^2 \cdot 3(x-2)^2(7x-6) + x^2(x-2)^3(7)$$

$$= x(x-2)^2[2(x-2)(7x-6) + 3x(7x-6) + 7x(x-2)]$$

$$= x(x-2)^2[42x^2 - 72x + 24] = 6x(x-2)^2(7x^2 - 12x + 4)$$

From the graph of f , it seems that f is CD on $(-\infty, 0)$, CU on $(0, 0.5)$, CD on $(0.5, 1.3)$, and CU on $(1.3, \infty)$. The points of inflection appear to be at $(0, 0)$, $(0.5, 0.5)$, and $(1.3, 0.6)$.

From the graph of f'' (and zooming in near the zeros), it seems that f is CD on $(-\infty, 0)$, CU on $(0, 0.45)$, CD on $(0.45, 1.26)$, and CU on $(1.26, \infty)$. Refined estimates of the inflection points are $(0, 0)$, $(0.45, 0.53)$, and $(1.26, 0.60)$.

45. In Maple, we define f and then use the command

`plot(diff(diff(f,x),x),x=-3..3);` In Mathematica, we

define f and then use `Plot[Dt[Dt[f,x],x],{x,-3,3}]`. We

see that $f'' > 0$ for $x > 0.1$ and $f'' < 0$ for $x < 0.1$. So f is concave up on $(0.1, \infty)$ and concave down on $(-\infty, 0.1)$.

46. It appears that f'' is positive (and thus f is concave up) on $(-1.8, 0.3)$ and $(1.5, \infty)$ and negative (so f is concave down) on $(-\infty, -1.8)$ and $(0.3, 1.5)$.

47. Most students learn more in the third hour of studying than in the eighth hour, so $K(3) - K(2)$ is larger than $K(8) - K(7)$. In other words, as you begin studying for a test, the rate of knowledge gain is large and then starts to taper off, so $K'(t)$ decreases and the graph of K is concave downward.

48. At first the depth increases slowly because the base of the mug is wide. But as the mug narrows, the coffee rises more quickly. Thus, the depth d increases at an increasing rate and its graph is concave upward. The rate of increase of d has a maximum where the mug is narrowest; that is, when the mug is half full. It is there that the inflection point (IP) occurs. Then the rate of increase of d starts to decrease as the mug widens and the graph becomes concave down.

49. $f(x) = \tan x - x \Rightarrow f'(x) = \sec^2 x - 1 > 0$ for $0 < x < \frac{\pi}{2}$ since $\sec^2 x > 1$ for $0 < x < \frac{\pi}{2}$. So f is increasing on $(0, \frac{\pi}{2})$. Thus, $f(x) > f(0) = 0$ for $0 < x < \frac{\pi}{2} \Rightarrow \tan x - x > 0 \Rightarrow \tan x > x$ for $0 < x < \frac{\pi}{2}$.
50. Let $f(x) = 2\sqrt{x} - 3 + 1/x$. Then $f'(x) = 1/\sqrt{x} - 1/x^2 > 0$ for $x > 1$ since for $x > 1$, $x^2 > x > \sqrt{x}$. Hence, f is increasing, so for $x > 1$, $f(x) > f(1) = 0$ or $2\sqrt{x} - 3 + 1/x > 0$ for $x > 1$. Hence, $2\sqrt{x} > 3 - 1/x$ for $x > 1$.
51. $f(x) = ax^3 + bx^2 + cx + d \Rightarrow f'(x) = 3ax^2 + 2bx + c$. We are given that $f(1) = 0$ and $f(-2) = 3$, so $f(1) = a + b + c + d = 0$ and $f(-2) = -8a + 4b - 2c + d = 3$. Also $f'(1) = 3a + 2b + c = 0$ and $f'(-2) = 12a - 4b + c = 0$ by Fermat's Theorem. Solving these four equations, we get $a = \frac{2}{9}$, $b = \frac{1}{3}$, $c = -\frac{4}{3}$, $d = \frac{7}{9}$, so the function is $f(x) = \frac{1}{9}(2x^3 + 3x^2 - 12x + 7)$.
52. $f(x) = x^3 + ax^2 + bx + 2 \Rightarrow f'(x) = 3x^2 + 2ax + b$. If $x = -3$ is an extremum, then $f'(-3) = 27 - 6a + b = 0 \Leftrightarrow b = 6a - 27$. If $x = -1$ is an extremum, then $f'(-1) = 3 - 2a + b = 0 \Leftrightarrow b = 2a - 3$. So $b = 2a - 3$ and $b = 6a - 27 \Rightarrow b = 9, a = 6$. Then $f'(x) = 3x^2 + 12x + 9 = 3(x + 1)(x + 3)$ and the First Derivative Test shows that f has a local maximum when $x = -3$ and a local minimum when $x = -1$.

53. Suppose that f is differentiable on an interval I and $f'(x) > 0$ for all x in I except $x = c$. To show that f is increasing on I , let x_1, x_2 be two numbers in I with $x_1 < x_2$.

Case 1 $x_1 < x_2 < c$. Let J be the interval $\{x \in I \mid x < c\}$. By applying the Increasing/Decreasing Test to f on J , we see that f is increasing on J , so $f(x_1) < f(x_2)$.

Case 2 $c < x_1 < x_2$. Apply the Increasing/Decreasing Test to f on $K = \{x \in I \mid x > c\}$.

Case 3 $x_1 < x_2 = c$. Apply the proof of the Increasing/Decreasing Test, using the Mean Value Theorem (MVT) on the interval $[x_1, x_2]$ and noting that the MVT does not require f to be differentiable at the endpoints of $[x_1, x_2]$.

Case 4 $c = x_1 < x_2$. Same proof as in Case 3.

Case 5 $x_1 < c < x_2$. By Cases 3 and 4, f is increasing on $[x_1, c]$ and on $[c, x_2]$, so $f(x_1) < f(c) < f(x_2)$.

In all cases, we have shown that $f(x_1) < f(x_2)$. Since x_1, x_2 were any numbers in I with $x_1 < x_2$, we have shown that f is increasing on I .

54. (a) We will make use of the converse of the Concavity Test (along with the stated assumptions); that is, if f is concave upward on I , then $f'' > 0$ on I . If f and g are CU on I , then $f'' > 0$ and $g'' > 0$ on I , so $(f + g)'' = f'' + g'' > 0$ on $I \Rightarrow f + g$ is CU on I .

(b) Since f is positive and CU on I , $f > 0$ and $f'' > 0$ on I . So $g(x) = [f(x)]^2 \Rightarrow g' = 2ff' \Rightarrow g'' = 2f'f' + 2ff'' = 2(f')^2 + 2ff'' > 0 \Rightarrow g$ is CU on I .

55. (a) Since f and g are positive, increasing, and CU on I with f'' and g'' never equal to 0, we have $f > 0$, $f' \geq 0$, $f'' > 0$, $g > 0$, $g' \geq 0$, $g'' > 0$ on I . Then $(fg)' = f'g + fg' \Rightarrow (fg)'' = f''g + 2f'g' + fg'' \geq f''g + fg'' > 0$ on $I \Rightarrow fg$ is CU on I .

(b) In part (a), if f and g are both decreasing instead of increasing, then $f' \leq 0$ and $g' \leq 0$ on I , so we still have $2f'g' \geq 0$ on I . Thus, $(fg)'' = f''g + 2f'g' + fg'' \geq f''g + fg'' > 0$ on $I \Rightarrow fg$ is CU on I as in part (a).

(c) Suppose f is increasing and g is decreasing [with f and g positive and CU]. Then $f' \geq 0$ and $g' \leq 0$ on I , so $2f'g' \leq 0$ on I and the argument in parts (a) and (b) fails.

Example 1. $I = (0, \infty)$, $f(x) = x^3$, $g(x) = 1/x$. Then $(fg)(x) = x^2$, so $(fg)'(x) = 2x$ and $(fg)''(x) = 2 > 0$ on I . Thus, fg is CU on I .

Example 2. $I = (0, \infty)$, $f(x) = 4x\sqrt{x}$, $g(x) = 1/x$. Then $(fg)(x) = 4\sqrt{x}$, so $(fg)'(x) = 2/\sqrt{x}$ and $(fg)''(x) = -1/\sqrt{x^3} < 0$ on I . Thus, fg is CD on I .

Example 3. $I = (0, \infty)$, $f(x) = x^2$, $g(x) = 1/x$. Thus, $(fg)(x) = x$, so fg is linear on I .

56. Since f and g are CU on $(-\infty, \infty)$, $f'' > 0$ and $g'' > 0$ on $(-\infty, \infty)$.

$$h(x) = f(g(x)) \Rightarrow h'(x) = f'(g(x))g'(x) \Rightarrow$$

$$h''(x) = f''(g(x))g'(x)g'(x) + f'(g(x))g''(x) = f''(g(x))[g'(x)]^2 + f'(g(x))g''(x) > 0 \text{ if } f' > 0.$$

So h is CU if f is increasing.

57. Let the cubic function be $f(x) = ax^3 + bx^2 + cx + d \Rightarrow f'(x) = 3ax^2 + 2bx + c \Rightarrow f''(x) = 6ax + 2b$. So f is CU when $6ax + 2b > 0 \Leftrightarrow x > -b/(3a)$, CD when $x < -b/(3a)$, and so the only point of inflection occurs when $x = -b/(3a)$. If the graph has three x -intercepts x_1, x_2 and x_3 , then the expression for $f(x)$ must factor as $f(x) = a(x - x_1)(x - x_2)(x - x_3)$. Multiplying these factors together gives us $f(x) = a[x^3 - (x_1 + x_2 + x_3)x^2 + (x_1x_2 + x_1x_3 + x_2x_3)x - x_1x_2x_3]$. Equating the coefficients of the x^2 -terms for the two forms of f gives us $b = -a(x_1 + x_2 + x_3)$. Hence, the x -coordinate of the point of inflection is $-\frac{b}{3a} = -\frac{-a(x_1 + x_2 + x_3)}{3a} = \frac{x_1 + x_2 + x_3}{3}$.
58. $P(x) = x^4 + cx^3 + x^2 \Rightarrow P'(x) = 4x^3 + 3cx^2 + 2x \Rightarrow P''(x) = 12x^2 + 6cx + 2$. The graph of $P''(x)$ is a parabola. If $P''(x)$ has two roots, then it changes sign twice and so has two inflection points. This happens when the discriminant of $P''(x)$ is positive, that is, $(6c)^2 - 4 \cdot 12 \cdot 2 > 0 \Leftrightarrow 36c^2 - 96 > 0 \Leftrightarrow |c| > \frac{2\sqrt{6}}{3} \approx 1.63$. If $36c^2 - 96 = 0 \Leftrightarrow c = \pm \frac{2\sqrt{6}}{3}$, $P''(x)$ is 0 at one point, but there is still no inflection point since $P''(x)$ never changes sign, and if $36c^2 - 96 < 0 \Leftrightarrow |c| < \frac{2\sqrt{6}}{3}$, then $P''(x)$ never changes sign, and so there is no inflection point.

 $c = 6$  $c = 3$  $c = 1.8$  $c = \frac{2\sqrt{6}}{3}$  $c = 0$  $c = -2$

For large positive c , the graph of f has two inflection points and a large dip to the left of the y -axis. As c decreases, the graph of f becomes flatter for $x < 0$, and eventually the dip rises above the x -axis, and then disappears entirely, along with the inflection points. As c continues to decrease, the dip and the inflection points reappear, to the right of the origin.

59. By hypothesis $g = f'$ is differentiable on an open interval containing c . Since $(c, f(c))$ is a point of inflection, the concavity changes at $x = c$, so $f''(x)$ changes signs at $x = c$. Hence, by the First Derivative Test, f' has a local extremum at $x = c$. Thus, by Fermat's Theorem $f''(c) = 0$.
60. $f(x) = x^4 \Rightarrow f'(x) = 4x^3 \Rightarrow f''(x) = 12x^2 \Rightarrow f''(0) = 0$. For $x < 0$, $f''(x) > 0$, so f is CU on $(-\infty, 0)$; for $x > 0$, $f''(x) > 0$, so f is also CU on $(0, \infty)$. Since f does not change concavity at 0, $(0, 0)$ is not an inflection point.

61. Using the fact that $|x| = \sqrt{x^2}$, we have that $g(x) = x\sqrt{x^2} \Rightarrow g'(x) = \sqrt{x^2} + \sqrt{x^2} = 2\sqrt{x^2} = 2|x| \Rightarrow g''(x) = 2x(x^2)^{-1/2} = \frac{2x}{|x|} < 0$ for $x < 0$ and $g''(x) > 0$ for $x > 0$, so $(0, 0)$ is an inflection point. But $g''(0)$ does not exist.
62. There must exist some interval containing c on which f''' is positive, since $f'''(c)$ is positive and f''' is continuous. On this interval, f'' is increasing (since f''' is positive), so $f'' = (f')'$ changes from negative to positive at c . So by the First Derivative Test, f' has a local minimum at $x = c$ and thus cannot change sign there, so f has no maximum or minimum at c . But since f'' changes from negative to positive at c , f has a point of inflection at c (it changes from concave down to concave up).

4.4 Limits at Infinity; Horizontal Asymptotes

1. (a) As x becomes large, the values of $f(x)$ approach 5.

(b) As x becomes large negative, the values of $f(x)$ approach 3.

2. (a) The graph of a function can intersect a vertical asymptote in the sense that it can meet but not cross it.

The graph of a function can intersect a horizontal asymptote. It can even intersect its horizontal asymptote an infinite number of times.

- (b) The graph of a function can have 0, 1, or 2 horizontal asymptotes. Representative examples are shown.

No horizontal asymptote

One horizontal asymptote

Two horizontal asymptotes

3. (a) $\lim_{x \rightarrow 2} f(x) = \infty$

(c) $\lim_{x \rightarrow -1^+} f(x) = -\infty$

(e) $\lim_{x \rightarrow -\infty} f(x) = 2$

(b) $\lim_{x \rightarrow -1^-} f(x) = \infty$

(d) $\lim_{x \rightarrow \infty} f(x) = 1$

(f) Vertical: $x = -1, x = 2$; Horizontal: $y = 1, y = 2$

4. (a) $\lim_{x \rightarrow \infty} g(x) = 2$

(b) $\lim_{x \rightarrow -\infty} g(x) = -2$

(c) $\lim_{x \rightarrow 3} g(x) = \infty$

(d) $\lim_{x \rightarrow 0} g(x) = -\infty$

(e) $\lim_{x \rightarrow -2^+} g(x) = -\infty$

(f) Vertical: $x = -2, x = 0, x = 3$; Horizontal: $y = -2, y = 2$

5. If $f(x) = x^2/2^x$, then a calculator gives $f(0) = 0, f(1) = 0.5, f(2) = 1, f(3) = 1.125, f(4) = 1, f(5) = 0.78125, f(6) = 0.5625, f(7) = 0.3828125, f(8) = 0.25, f(9) = 0.158203125, f(10) = 0.09765625, f(20) \approx 0.00038147, f(50) \approx 2.2204 \times 10^{-12}, f(100) \approx 7.8886 \times 10^{-27}$.
It appears that $\lim_{x \rightarrow \infty} (x^2/2^x) = 0$.

6. (a) From a graph of $f(x) = (1 - 2/x)^x$ in a window of $[0, 10,000]$ by $[0, 0.2]$, we estimate that $\lim_{x \rightarrow \infty} f(x) = 0.14$ (to two decimal places.)

(b)

x	$f(x)$
10,000	0.135308
100,000	0.135333
1,000,000	0.135335

From the table, we estimate that $\lim_{x \rightarrow \infty} f(x) = 0.1353$

(to four decimal places.)

7. $\lim_{x \rightarrow \infty} \frac{3x^2 - x + 4}{2x^2 + 5x - 8} = \lim_{x \rightarrow \infty} \frac{(3x^2 - x + 4)/x^2}{(2x^2 + 5x - 8)/x^2}$

[divide both the numerator and denominator by x^2
(the highest power of x that
appears in the denominator)]

$$= \frac{\lim_{x \rightarrow \infty} (3 - 1/x + 4/x^2)}{\lim_{x \rightarrow \infty} (2 + 5/x - 8/x^2)}$$

[Limit Law 5]

$$= \frac{\lim_{x \rightarrow \infty} 3 - \lim_{x \rightarrow \infty} (1/x) + \lim_{x \rightarrow \infty} (4/x^2)}{\lim_{x \rightarrow \infty} 2 + \lim_{x \rightarrow \infty} (5/x) - \lim_{x \rightarrow \infty} (8/x^2)}$$

[Limit Laws 1 and 2]

$$= \frac{3 - \lim_{x \rightarrow \infty} (1/x) + 4 \lim_{x \rightarrow \infty} (1/x^2)}{2 + 5 \lim_{x \rightarrow \infty} (1/x) - 8 \lim_{x \rightarrow \infty} (1/x^2)}$$

[Limit Laws 7 and 3]

$$= \frac{3 - 0 + 4(0)}{2 + 5(0) - 8(0)}$$

[Theorem 4]

$$= \frac{3}{2}$$

8. $\lim_{x \rightarrow \infty} \sqrt{\frac{12x^3 - 5x + 2}{1 + 4x^2 + 3x^3}} = \sqrt{\lim_{x \rightarrow \infty} \frac{12x^3 - 5x + 2}{1 + 4x^2 + 3x^3}}$

[Limit Law 11]

$$= \sqrt{\lim_{x \rightarrow \infty} \frac{12 - 5/x^2 + 2/x^3}{1/x^3 + 4/x + 3}}$$

[divide by x^3]

$$= \sqrt{\frac{\lim_{x \rightarrow \infty} (12 - 5/x^2 + 2/x^3)}{\lim_{x \rightarrow \infty} (1/x^3 + 4/x + 3)}}$$

[Limit Law 5]

$$\begin{aligned}
&= \sqrt{\frac{\lim_{x \rightarrow \infty} 12 - \lim_{x \rightarrow \infty} (5/x^2) + \lim_{x \rightarrow \infty} (2/x^3)}{\lim_{x \rightarrow \infty} (1/x^3) + \lim_{x \rightarrow \infty} (4/x) + \lim_{x \rightarrow \infty} 3}} \quad [\text{Limit Laws 1 and 2}] \\
&= \sqrt{\frac{12 - 5 \lim_{x \rightarrow \infty} (1/x^2) + 2 \lim_{x \rightarrow \infty} (1/x^3)}{\lim_{x \rightarrow \infty} (1/x^3) + 4 \lim_{x \rightarrow \infty} (1/x) + 3}} \quad [\text{Limit Laws 7 and 3}] \\
&= \sqrt{\frac{12 - 5(0) + 2(0)}{0 + 4(0) + 3}} \quad [\text{Theorem 4}] \\
&= \sqrt{\frac{12}{3}} = \sqrt{4} = 2
\end{aligned}$$

$$9. \lim_{x \rightarrow \infty} \frac{1}{2x+3} = \lim_{x \rightarrow \infty} \frac{1/x}{(2x+3)/x} = \frac{\lim_{x \rightarrow \infty} (1/x)}{\lim_{x \rightarrow \infty} (2+3/x)} = \frac{\lim_{x \rightarrow \infty} (1/x)}{\lim_{x \rightarrow \infty} 2+3 \lim_{x \rightarrow \infty} (1/x)} = \frac{0}{2+3(0)} = \frac{0}{2} = 0$$

$$10. \lim_{x \rightarrow \infty} \frac{3x+5}{x-4} = \lim_{x \rightarrow \infty} \frac{(3x+5)/x}{(x-4)/x} = \lim_{x \rightarrow \infty} \frac{3+5/x}{1-4/x} = \frac{\lim_{x \rightarrow \infty} 3+5 \lim_{x \rightarrow \infty} \frac{1}{x}}{\lim_{x \rightarrow \infty} 1-4 \lim_{x \rightarrow \infty} \frac{1}{x}} = \frac{3+5(0)}{1-4(0)} = 3$$

$$\begin{aligned}
11. \lim_{x \rightarrow -\infty} \frac{1-x-x^2}{2x^2-7} &= \lim_{x \rightarrow -\infty} \frac{(1-x-x^2)/x^2}{(2x^2-7)/x^2} = \frac{\lim_{x \rightarrow -\infty} (1/x^2 - 1/x - 1)}{\lim_{x \rightarrow -\infty} (2 - 7/x^2)} \\
&= \frac{\lim_{x \rightarrow -\infty} (1/x^2) - \lim_{x \rightarrow -\infty} (1/x) - \lim_{x \rightarrow -\infty} 1}{\lim_{x \rightarrow -\infty} 2 - 7 \lim_{x \rightarrow -\infty} (1/x^2)} = \frac{0 - 0 - 1}{2 - 7(0)} = -\frac{1}{2}
\end{aligned}$$

$$12. \lim_{y \rightarrow \infty} \frac{2-3y^2}{5y^2+4y} = \lim_{y \rightarrow \infty} \frac{(2-3y^2)/y^2}{(5y^2+4y)/y^2} = \frac{\lim_{y \rightarrow \infty} (2/y^2 - 3)}{\lim_{y \rightarrow \infty} (5+4/y)} = \frac{2 \lim_{y \rightarrow \infty} (1/y^2) - \lim_{y \rightarrow \infty} 3}{\lim_{y \rightarrow \infty} 5+4 \lim_{y \rightarrow \infty} (1/y)} = \frac{2(0)-3}{5+4(0)} = -\frac{3}{5}$$

13. Divide both the numerator and denominator by x^3 (the highest power of x that occurs in the denominator).

$$\begin{aligned}
\lim_{x \rightarrow \infty} \frac{x^3+5x}{2x^3-x^2+4} &= \lim_{x \rightarrow \infty} \frac{\frac{x^3+5x}{x^3}}{\frac{2x^3-x^2+4}{x^3}} = \lim_{x \rightarrow \infty} \frac{1+\frac{5}{x^2}}{2-\frac{1}{x}+\frac{4}{x^3}} = \frac{\lim_{x \rightarrow \infty} \left(1+\frac{5}{x^2}\right)}{\lim_{x \rightarrow \infty} \left(2-\frac{1}{x}+\frac{4}{x^3}\right)} \\
&= \frac{\lim_{x \rightarrow \infty} 1+5 \lim_{x \rightarrow \infty} \frac{1}{x^2}}{\lim_{x \rightarrow \infty} 2-\lim_{x \rightarrow \infty} \frac{1}{x}+4 \lim_{x \rightarrow \infty} \frac{1}{x^3}} = \frac{1+5(0)}{2-0+4(0)} = \frac{1}{2}
\end{aligned}$$

$$14. \lim_{t \rightarrow -\infty} \frac{t^2+2}{t^3+t^2-1} = \lim_{t \rightarrow -\infty} \frac{(t^2+2)/t^3}{(t^3+t^2-1)/t^3} = \lim_{t \rightarrow -\infty} \frac{1/t+2/t^3}{1+1/t-1/t^3} = \frac{0+0}{1+0-0} = 0$$

15. First, multiply the factors in the denominator. Then divide both the numerator and denominator by u^4 .

$$\begin{aligned}\lim_{u \rightarrow \infty} \frac{4u^4 + 5}{(u^2 - 2)(2u^2 - 1)} &= \lim_{u \rightarrow \infty} \frac{4u^4 + 5}{2u^4 - 5u^2 + 2} = \lim_{u \rightarrow \infty} \frac{\frac{4u^4 + 5}{u^4}}{\frac{2u^4 - 5u^2 + 2}{u^4}} = \lim_{u \rightarrow \infty} \frac{4 + \frac{5}{u^4}}{2 - \frac{5}{u^2} + \frac{2}{u^4}} \\&= \frac{\lim_{u \rightarrow \infty} \left(4 + \frac{5}{u^4}\right)}{\lim_{u \rightarrow \infty} \left(2 - \frac{5}{u^2} + \frac{2}{u^4}\right)} = \frac{\lim_{u \rightarrow \infty} 4 + 5 \lim_{u \rightarrow \infty} \frac{1}{u^4}}{\lim_{u \rightarrow \infty} 2 - 5 \lim_{u \rightarrow \infty} \frac{1}{u^2} + 2 \lim_{u \rightarrow \infty} \frac{1}{u^4}} = \frac{4 + 5(0)}{2 - 5(0) + 2(0)} \\&= \frac{4}{2} = 2\end{aligned}$$

$$16. \lim_{x \rightarrow \infty} \frac{x+2}{\sqrt{9x^2+1}} = \lim_{x \rightarrow \infty} \frac{(x+2)/x}{\sqrt{9x^2+1}/\sqrt{x^2}} = \lim_{x \rightarrow \infty} \frac{1+2/x}{\sqrt{9+1/x^2}} = \frac{1+0}{\sqrt{9+0}} = \frac{1}{3}$$

$$\begin{aligned}17. \lim_{x \rightarrow \infty} \frac{\sqrt{9x^6-x}}{x^3+1} &= \lim_{x \rightarrow \infty} \frac{\sqrt{9x^6-x}/x^3}{(x^3+1)/x^3} = \frac{\lim_{x \rightarrow \infty} \sqrt{(9x^6-x)/x^6}}{\lim_{x \rightarrow \infty} (1+1/x^3)} \quad [\text{since } x^3 = \sqrt{x^6} \text{ for } x > 0] \\&= \frac{\lim_{x \rightarrow \infty} \sqrt{9-1/x^5}}{\lim_{x \rightarrow \infty} 1 + \lim_{x \rightarrow \infty} (1/x^3)} = \frac{\sqrt{\lim_{x \rightarrow \infty} 9 - \lim_{x \rightarrow \infty} (1/x^5)}}{1+0} \\&= \sqrt{9-0} = 3\end{aligned}$$

$$\begin{aligned}18. \lim_{x \rightarrow -\infty} \frac{\sqrt{9x^6-x}}{x^3+1} &= \lim_{x \rightarrow -\infty} \frac{\sqrt{9x^6-x}/x^3}{(x^3+1)/x^3} = \frac{\lim_{x \rightarrow -\infty} -\sqrt{(9x^6-x)/x^6}}{\lim_{x \rightarrow -\infty} (1+1/x^3)} \quad [\text{since } x^3 = -\sqrt{x^6} \text{ for } x < 0] \\&= \frac{\lim_{x \rightarrow -\infty} -\sqrt{9-1/x^5}}{\lim_{x \rightarrow -\infty} 1 + \lim_{x \rightarrow -\infty} (1/x^3)} = \frac{-\sqrt{\lim_{x \rightarrow -\infty} 9 - \lim_{x \rightarrow -\infty} (1/x^5)}}{1+0} \\&= -\sqrt{9-0} = -3\end{aligned}$$

$$19. \lim_{x \rightarrow -\infty} \frac{x}{\sqrt{x^2+4}} = \lim_{x \rightarrow -\infty} \frac{x/\sqrt{x^2}}{\sqrt{x^2+4}/\sqrt{x^2}} = \lim_{x \rightarrow -\infty} \frac{-1}{\sqrt{1+4/x^2}} \quad [\text{since } -x = |x| = \sqrt{x^2} \text{ for } x < 0] = -1$$

$$\begin{aligned}20. \lim_{x \rightarrow \infty} (\sqrt{x^4+6x^2} - x^2) &= \lim_{x \rightarrow \infty} \frac{\sqrt{x^4+6x^2} - x^2}{1} \cdot \frac{\sqrt{x^4+6x^2} + x^2}{\sqrt{x^4+6x^2} + x^2} = \lim_{x \rightarrow \infty} \frac{(x^4+6x^2) - x^4}{\sqrt{x^4+6x^2} + x^2} \\&= \lim_{x \rightarrow \infty} \frac{6x^2}{\sqrt{x^4+6x^2} + x^2} = \lim_{x \rightarrow \infty} \frac{6x^2/x^2}{(\sqrt{x^4+6x^2} + x^2)/\sqrt{x^4}} \\&= \lim_{x \rightarrow \infty} \frac{6}{\sqrt{1+6/x^2} + 1} = \frac{6}{1+1} = 3\end{aligned}$$

$$\begin{aligned}21. \lim_{x \rightarrow \infty} (\sqrt{9x^2+x} - 3x) &= \lim_{x \rightarrow \infty} \frac{(\sqrt{9x^2+x} - 3x)(\sqrt{9x^2+x} + 3x)}{\sqrt{9x^2+x} + 3x} = \lim_{x \rightarrow \infty} \frac{(\sqrt{9x^2+x})^2 - (3x)^2}{\sqrt{9x^2+x} + 3x} \\&= \lim_{x \rightarrow \infty} \frac{(9x^2+x) - 9x^2}{\sqrt{9x^2+x} + 3x} = \lim_{x \rightarrow \infty} \frac{x}{\sqrt{9x^2+x} + 3x} \cdot \frac{1/x}{1/x} \\&= \lim_{x \rightarrow \infty} \frac{x/x}{\sqrt{9x^2/x^2 + x/x^2} + 3x/x} = \lim_{x \rightarrow \infty} \frac{1}{\sqrt{9+1/x} + 3} = \frac{1}{\sqrt{9+0} + 3} = \frac{1}{3+3} = \frac{1}{6}\end{aligned}$$

$$\begin{aligned}
 22. \lim_{x \rightarrow -\infty} (x + \sqrt{x^2 + 2x}) &= \lim_{x \rightarrow -\infty} (x + \sqrt{x^2 + 2x}) \left[\frac{x - \sqrt{x^2 + 2x}}{x - \sqrt{x^2 + 2x}} \right] = \lim_{x \rightarrow -\infty} \frac{x^2 - (x^2 + 2x)}{x - \sqrt{x^2 + 2x}} \\
 &= \lim_{x \rightarrow -\infty} \frac{-2x}{x - \sqrt{x^2 + 2x}} = \lim_{x \rightarrow -\infty} \frac{-2}{1 + \sqrt{1 + 2/x}} = \frac{-2}{1 + \sqrt{1 + 2(0)}} = -1
 \end{aligned}$$

Note: In dividing numerator and denominator by x , we used the fact that for $x < 0$, $x = -\sqrt{x^2}$.

$$\begin{aligned}
 23. \lim_{x \rightarrow \infty} (\sqrt{x^2 + ax} - \sqrt{x^2 + bx}) &= \lim_{x \rightarrow \infty} \frac{(\sqrt{x^2 + ax} - \sqrt{x^2 + bx})(\sqrt{x^2 + ax} + \sqrt{x^2 + bx})}{\sqrt{x^2 + ax} + \sqrt{x^2 + bx}} \\
 &= \lim_{x \rightarrow \infty} \frac{(x^2 + ax) - (x^2 + bx)}{\sqrt{x^2 + ax} + \sqrt{x^2 + bx}} = \lim_{x \rightarrow \infty} \frac{[(a - b)x]/x}{(\sqrt{x^2 + ax} + \sqrt{x^2 + bx})/\sqrt{x^2}} \\
 &= \lim_{x \rightarrow \infty} \frac{a - b}{\sqrt{1 + a/x} + \sqrt{1 + b/x}} = \frac{a - b}{\sqrt{1 + 0} + \sqrt{1 + 0}} = \frac{a - b}{2}
 \end{aligned}$$

24. $\lim_{x \rightarrow \infty} \cos x$ does not exist because as x increases $\cos x$ does not approach any one value, but oscillates between 1 and -1 .

25. $\sqrt{x}$ is large when x is large, so $\lim_{x \rightarrow \infty} \sqrt{x} = \infty$.

26. $\sqrt[3]{x}$ is large negative when x is large negative, so $\lim_{x \rightarrow -\infty} \sqrt[3]{x} = -\infty$.

27. $\lim_{x \rightarrow \infty} (x - \sqrt{x}) = \lim_{x \rightarrow \infty} \sqrt{x}(\sqrt{x} - 1) = \infty$ since $\sqrt{x} \rightarrow \infty$ and $\sqrt{x} - 1 \rightarrow \infty$ as $x \rightarrow \infty$.

$$\begin{aligned}
 28. \lim_{x \rightarrow \infty} \frac{x^3 - 2x + 3}{5 - 2x^2} &= \lim_{x \rightarrow \infty} \frac{(x^3 - 2x + 3)/x^2}{(5 - 2x^2)/x^2} \quad [\text{divide by the highest power of } x \text{ in the denominator}] \\
 &= \lim_{x \rightarrow \infty} \frac{x - 2/x + 3/x^2}{5/x^2 - 2} = -\infty \text{ because } x - 2/x + 3/x^2 \rightarrow \infty \text{ and } 5/x^2 - 2 \rightarrow -2 \text{ as } x \rightarrow \infty.
 \end{aligned}$$

29. $\lim_{x \rightarrow -\infty} (x^4 + x^5) = \lim_{x \rightarrow -\infty} x^5(\frac{1}{x} + 1)$ [factor out the largest power of x] $= -\infty$ because $x^5 \rightarrow -\infty$ and $1/x + 1 \rightarrow 1$ as $x \rightarrow -\infty$.

30. $\lim_{x \rightarrow \infty} (x^2 - x^4) = \lim_{x \rightarrow \infty} x^2(1 - x^2) = -\infty$ since $x^2 \rightarrow \infty$ and $1 - x^2 \rightarrow -\infty$.

$$\begin{aligned}
 31. \lim_{x \rightarrow \infty} \frac{x + x^3 + x^5}{1 - x^2 + x^4} &= \lim_{x \rightarrow \infty} \frac{(x + x^3 + x^5)/x^4}{(1 - x^2 + x^4)/x^4} \quad [\text{divide by the highest power of } x \text{ in the denominator}] \\
 &= \lim_{x \rightarrow \infty} \frac{1/x^3 + 1/x + x}{1/x^4 - 1/x^2 + 1} = \infty
 \end{aligned}$$

because $(1/x^3 + 1/x + x) \rightarrow \infty$ and $(1/x^4 - 1/x^2 + 1) \rightarrow 1$ as $x \rightarrow \infty$.

32. If $t = \frac{1}{x}$, then $\lim_{x \rightarrow \infty} x \sin \frac{1}{x} = \lim_{t \rightarrow 0^+} \frac{1}{t} \sin t = \lim_{t \rightarrow 0^+} \frac{\sin t}{t} = 1$.

33. (a)

From the graph of $f(x) = \sqrt{x^2 + x + 1} + x$, we estimate the value of $\lim_{x \rightarrow -\infty} f(x)$ to be -0.5 .

(b)

x	$f(x)$
-10,000	-0.4999625
-100,000	-0.4999962
-1,000,000	-0.4999996

From the table, we estimate the limit to be -0.5 .

$$\begin{aligned}
 \text{(c)} \quad \lim_{x \rightarrow -\infty} (\sqrt{x^2 + x + 1} + x) &= \lim_{x \rightarrow -\infty} (\sqrt{x^2 + x + 1} + x) \left[\frac{\sqrt{x^2 + x + 1} - x}{\sqrt{x^2 + x + 1} - x} \right] = \lim_{x \rightarrow -\infty} \frac{(x^2 + x + 1) - x^2}{\sqrt{x^2 + x + 1} - x} \\
 &= \lim_{x \rightarrow -\infty} \frac{(x+1)(1/x)}{(\sqrt{x^2 + x + 1} - x)(1/x)} = \lim_{x \rightarrow -\infty} \frac{1 + (1/x)}{-\sqrt{1 + (1/x) + (1/x^2)} - 1} \\
 &= \frac{1 + 0}{-\sqrt{1 + 0 + 0} - 1} = -\frac{1}{2}
 \end{aligned}$$

Note that for $x < 0$, we have $\sqrt{x^2} = |x| = -x$, so when we divide the radical by x , with $x < 0$, we get

$$\frac{1}{x} \sqrt{x^2 + x + 1} = -\frac{1}{\sqrt{x^2}} \sqrt{x^2 + x + 1} = -\sqrt{1 + (1/x) + (1/x^2)}.$$

34. (a)

From the graph of

$$f(x) = \sqrt{3x^2 + 8x + 6} - \sqrt{3x^2 + 3x + 1}, \text{ we estimate}$$

(to one decimal place) the value of $\lim_{x \rightarrow \infty} f(x)$ to be 1.4.

(b)

x	$f(x)$
10,000	1.44339
100,000	1.44338
1,000,000	1.44338

From the table, we estimate (to four decimal places) the limit to be 1.4434.

$$\begin{aligned}
 \text{(c)} \quad \lim_{x \rightarrow \infty} f(x) &= \lim_{x \rightarrow \infty} \frac{(\sqrt{3x^2 + 8x + 6} - \sqrt{3x^2 + 3x + 1})(\sqrt{3x^2 + 8x + 6} + \sqrt{3x^2 + 3x + 1})}{\sqrt{3x^2 + 8x + 6} + \sqrt{3x^2 + 3x + 1}} \\
 &= \lim_{x \rightarrow \infty} \frac{(3x^2 + 8x + 6) - (3x^2 + 3x + 1)}{\sqrt{3x^2 + 8x + 6} + \sqrt{3x^2 + 3x + 1}} \\
 &= \lim_{x \rightarrow \infty} \frac{(5x + 5)(1/x)}{(\sqrt{3x^2 + 8x + 6} + \sqrt{3x^2 + 3x + 1})(1/x)} \\
 &= \lim_{x \rightarrow \infty} \frac{5 + 5/x}{\sqrt{3 + 8/x + 6/x^2} + \sqrt{3 + 3/x + 1/x^2}} = \frac{5}{\sqrt{3} + \sqrt{3}} = \frac{5}{2\sqrt{3}} = \frac{5\sqrt{3}}{6} \approx 1.443376
 \end{aligned}$$

35. $\lim_{x \rightarrow \pm\infty} \frac{x}{x+4} = \lim_{x \rightarrow \pm\infty} \frac{1}{1+4/x} = \frac{1}{1+0} = 1$, so $y = 1$ is a horizontal asymptote. $\lim_{x \rightarrow -4^-} \frac{x}{x+4} = \infty$ and $\lim_{x \rightarrow -4^+} \frac{x}{x+4} = -\infty$, so $x = -4$ is a vertical asymptote. The graph confirms these calculations.

36. Since $x^2 - 1 \rightarrow 0$ as $x \rightarrow \pm 1$ and $y < 0$ for $-1 < x < 1$ and $y > 0$ for $x < -1$ and $x > 1$, we have $\lim_{x \rightarrow 1^-} \frac{x^2 + 4}{x^2 - 1} = -\infty$, $\lim_{x \rightarrow 1^+} \frac{x^2 + 4}{x^2 - 1} = \infty$, $\lim_{x \rightarrow -1^-} \frac{x^2 + 4}{x^2 - 1} = \infty$, and $\lim_{x \rightarrow -1^+} \frac{x^2 + 4}{x^2 - 1} = -\infty$, so $x = 1$ and $x = -1$ are vertical asymptotes. Also $\lim_{x \rightarrow \pm\infty} \frac{x^2 + 4}{x^2 - 1} = \lim_{x \rightarrow \pm\infty} \frac{1 + 4/x^2}{1 - 1/x^2} = \frac{1+0}{1-0} = 1$, so $y = 1$ is a horizontal asymptote. The graph confirms these calculations.

37. $\lim_{x \rightarrow \pm\infty} \frac{x^3}{x^2 + 3x - 10} = \lim_{x \rightarrow \pm\infty} \frac{x}{1 + (3/x) - (10/x^2)} = \pm\infty$, so there is no horizontal asymptote.

$$\lim_{x \rightarrow 2^+} \frac{x^3}{x^2 + 3x - 10} = \lim_{x \rightarrow 2^+} \frac{x^3}{(x+5)(x-2)} = \infty, \text{ since}$$

$$\frac{x^3}{(x+5)(x-2)} > 0 \text{ for } x > 2. \text{ Similarly, } \lim_{x \rightarrow 2^-} \frac{x^3}{x^2 + 3x - 10} = -\infty,$$

$$\lim_{x \rightarrow -5^-} \frac{x^3}{x^2 + 3x - 10} = -\infty, \text{ and } \lim_{x \rightarrow -5^+} \frac{x^3}{x^2 + 3x - 10} = \infty, \text{ so}$$

$x = 2$ and $x = -5$ are vertical asymptotes. The graph confirms these calculations.

38. $\lim_{x \rightarrow \pm\infty} \frac{x^3 + 1}{x^3 + x} = \lim_{x \rightarrow \pm\infty} \frac{1 + 1/x^3}{1 + 1/x^2} = 1$, so $y = 1$ is a horizontal asymptote. Since $y = \frac{x^3 + 1}{x^3 + x} = \frac{x^3 + 1}{x(x^2 + 1)}$ > 0 for $x > 0$ and $y < 0$ for $-1 < x < 0$, $\lim_{x \rightarrow 0^+} \frac{x^3 + 1}{x^3 + x} = \infty$ and $\lim_{x \rightarrow 0^-} \frac{x^3 + 1}{x^3 + x} = -\infty$, so $x = 0$ is a vertical asymptote.

39. $\lim_{x \rightarrow \infty} \frac{x}{\sqrt[4]{x^4 + 1}} \cdot \frac{1/x}{1/\sqrt[4]{x^4}} = \lim_{x \rightarrow \infty} \frac{1}{\sqrt[4]{1 + \frac{1}{x^4}}} = \frac{1}{\sqrt[4]{1+0}} = 1$ and $\lim_{x \rightarrow -\infty} \frac{x}{\sqrt[4]{x^4 + 1}} \cdot \frac{1/x}{-1/\sqrt[4]{x^4}} = \lim_{x \rightarrow -\infty} \frac{1}{-\sqrt[4]{1 + \frac{1}{x^4}}} = \frac{1}{-\sqrt[4]{1+0}} = -1$, so $y = \pm 1$ are horizontal asymptotes. There is no vertical asymptote.

$$40. \lim_{x \rightarrow \infty} \frac{x-9}{\sqrt{4x^2+3x+2}} = \lim_{x \rightarrow \infty} \frac{1-9/x}{\sqrt{4+(3/x)+(2/x^2)}} = \frac{1-0}{\sqrt{4+0+0}} = \frac{1}{2}.$$

Using the fact that $\sqrt{x^2} = |x| = -x$ for $x < 0$, we divide the numerator by $-x$ and the denominator by $\sqrt{x^2}$.

$$\text{Thus, } \lim_{x \rightarrow -\infty} \frac{x-9}{\sqrt{4x^2+3x+2}} = \lim_{x \rightarrow -\infty} \frac{-1+9/x}{\sqrt{4+(3/x)+(2/x^2)}} = \frac{-1+0}{\sqrt{4+0+0}} = -\frac{1}{2}.$$

The horizontal asymptotes are $y = \pm \frac{1}{2}$. The

polynomial $4x^2 + 3x + 2$ is positive for all x ,

so the denominator never approaches zero,

and thus there is no vertical asymptote.

41. Let's look for a rational function.

$$(1) \lim_{x \rightarrow \pm\infty} f(x) = 0 \Rightarrow \text{degree of numerator} < \text{degree of denominator}$$

$$(2) \lim_{x \rightarrow 0} f(x) = -\infty \Rightarrow \text{there is a factor of } x^2 \text{ in the denominator (not just } x, \text{ since that would produce a sign change at } x = 0), \text{ and the function is negative near } x = 0.$$

$$(3) \lim_{x \rightarrow 3} f(x) = \infty \text{ and } \lim_{x \rightarrow 3^+} f(x) = -\infty \Rightarrow \text{vertical asymptote at } x = 3; \text{ there is a factor of } (x-3) \text{ in the denominator.}$$

$$(4) f(2) = 0 \Rightarrow 2 \text{ is an } x\text{-intercept; there is at least one factor of } (x-2) \text{ in the numerator.}$$

Combining all of this information and putting in a negative sign to give us the desired left- and right-hand limits

$$\text{gives us } f(x) = \frac{2-x}{x^2(x-3)} \text{ as one possibility.}$$

42. Since the function has vertical asymptotes $x = 1$ and $x = 3$, the denominator of the rational function we are looking for must have factors $(x-1)$ and $(x-3)$. Because the horizontal asymptote is $y = 1$, the degree of the numerator must equal the degree of the denominator, and the ratio of the leading coefficients must be 1. One possibility

$$\text{is } f(x) = \frac{x^2}{(x-1)(x-3)}.$$

43. $y = \frac{1-x}{1+x}$ has domain $(-\infty, -1) \cup (-1, \infty)$.

$$\lim_{x \rightarrow \pm\infty} \frac{1-x}{1+x} = \lim_{x \rightarrow \pm\infty} \frac{1/x-1}{1/x+1} = \frac{0-1}{0+1} = -1, \text{ so } y = -1 \text{ is a HA.}$$

The line $x = -1$ is a VA.

$$y' = \frac{(1+x)(-1) - (1-x)(1)}{(1+x)^2} = \frac{-2}{(1+x)^2} < 0 \text{ for } x \neq -1. \text{ Thus,}$$

$(-\infty, -1)$ and $(-1, \infty)$ are intervals of decrease.

$$y'' = -2 \cdot \frac{-2(1+x)}{[(1+x)^2]^2} = \frac{4}{(1+x)^3} < 0 \text{ for } x < -1 \text{ and } y'' > 0 \text{ for } x > -1, \text{ so the curve is CD on } (-\infty, -1)$$

and CU on $(-1, \infty)$. Since $x = -1$ is not in the domain, there is no IP.

44. $y = \frac{1+2x^2}{1+x^2}$ has domain $\mathbb{R}$.

$$\lim_{x \rightarrow \pm\infty} \frac{1+2x^2}{1+x^2} = \lim_{x \rightarrow \pm\infty} \frac{1/x^2 + 2}{1/x^2 + 1} = \frac{0+2}{0+1} = 2, \text{ so } y = 2 \text{ is a HA.}$$

$$\text{There is no VA. } y' = \frac{(1+x^2)(4x) - (1+2x^2)(2x)}{(1+x^2)^2} = \frac{2x}{(1+x^2)^2} > 0$$

$$\Leftrightarrow x > 0,$$

and $y' < 0 \Leftrightarrow x < 0$. Thus, y is increasing on $(0, \infty)$ and y is decreasing on $(-\infty, 0)$. There is a local (and

$$\text{absolute) minimum at } (0, 1). \quad y'' = \frac{(1+x^2)^2(2) - (2x) \cdot 2(1+x^2)(2x)}{[(1+x^2)^2]^2} = \frac{2-6x^2}{(1+x^2)^3} = 0 \Leftrightarrow x = \pm \frac{1}{\sqrt{3}}.$$

$$y'' > 0 \Leftrightarrow -\frac{1}{\sqrt{3}} < x < \frac{1}{\sqrt{3}}, \text{ so the curve is CU on } \left(-\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right) \text{ and CD on } \left(-\infty, -\frac{1}{\sqrt{3}}\right) \text{ and } \left(\frac{1}{\sqrt{3}}, \infty\right).$$

$$\text{There are IP at } \left(\pm \frac{1}{\sqrt{3}}, \frac{5}{4}\right).$$

45. $\lim_{x \rightarrow \pm\infty} \frac{x}{x^2+1} = \lim_{x \rightarrow \pm\infty} \frac{1/x}{1+1/x^2} = \frac{0}{1+0} = 0$, so $y = 0$ is a

horizontal asymptote.

$$y' = \frac{x^2+1-x(2x)}{(x^2+1)^2} = \frac{1-x^2}{(x^2+1)^2} = 0 \text{ when } x = \pm 1 \text{ and } y' > 0 \Leftrightarrow$$

$$x^2 < 1 \Leftrightarrow -1 < x < 1, \text{ so } y \text{ is increasing on } (-1, 1) \text{ and decreasing on } (-\infty, -1) \text{ and } (1, \infty).$$

$$y'' = \frac{(1+x^2)^2(-2x) - (1-x^2)2(x^2+1)2x}{(1+x^2)^4} = \frac{2x(x^2-3)}{(1+x^2)^3} > 0 \Leftrightarrow x > \sqrt{3} \text{ or } -\sqrt{3} < x < 0, \text{ so } y \text{ is}$$

$$\text{CU on } (\sqrt{3}, \infty) \text{ and } (-\sqrt{3}, 0) \text{ and CD on } (-\infty, -\sqrt{3}) \text{ and } (0, \sqrt{3}).$$

46. $y = \frac{x}{\sqrt{x^2+1}} = \frac{x/|x|}{\sqrt{1+1/x^2}}$ has domain $\mathbb{R}$. As $x \rightarrow \pm\infty$, $y \rightarrow \pm 1$, so

$$y = \pm 1 \text{ are HA. There is no VA. } y = x(x^2+1)^{-1/2} \Rightarrow$$

$$y' = x(-\frac{1}{2})(x^2+1)^{-3/2}(2x) + (x^2+1)^{-1/2}(1)$$

$$= (x^2+1)^{-3/2}[-x^2 + (x^2+1)]$$

$$= (x^2+1)^{-3/2} > 0 \text{ for all } x$$

$$\text{Thus, } y \text{ is increasing for all } x. \quad y'' = (-\frac{3}{2})(x^2+1)^{-5/2}(2x) = \frac{-3x}{(x^2+1)^{5/2}} > 0 \text{ for } x < 0. \text{ So the curve is CU}$$

$$\text{on } (-\infty, 0) \text{ and CD on } (0, \infty). \text{ There is an inflection point at } (0, 0).$$

47. $y = f(x) = x^2(x - 2)(1 - x)$. The y -intercept is $f(0) = 0$, and the x -intercepts occur when $y = 0 \Rightarrow x = 0, 1$, and 2 . Notice that, since x^2 is always positive, the graph does not cross the x -axis at 0 , but does cross the x -axis at 1 and 2 .

$\lim_{x \rightarrow \infty} x^2(x - 2)(1 - x) = -\infty$, since the first two factors are large positive and the third large negative when x is large positive. $\lim_{x \rightarrow -\infty} x^2(x - 2)(1 - x) = -\infty$ because the first and third factors are large positive and the second large negative as $x \rightarrow -\infty$.

48. $y = (2 + x)^3(1 - x)(3 - x)$. As $x \rightarrow \infty$, the first factor is large positive, and the second and third factors are large negative. Therefore, $\lim_{x \rightarrow \infty} f(x) = \infty$. As $x \rightarrow -\infty$, the first factor is large negative, and the second and third factors are large positive. Therefore, $\lim_{x \rightarrow -\infty} f(x) = -\infty$. Now the y -intercept is

$f(0) = (2)^3(1)(3) = 24$ and the x -intercepts are the solutions to $f(x) = 0$
 $\Rightarrow x = -2, 1$ and 3 , and the graph crosses the x -axis at all of these points.

49. $y = f(x) = (x + 4)^5(x - 3)^4$. The y -intercept is $f(0) = 4^5(-3)^4 = 82,944$. The x -intercepts occur when $y = 0 \Rightarrow x = -4, 3$. Notice that the graph does not cross the x -axis at 3 because $(x - 3)^4$ is always positive, but does cross the x -axis at -4 . $\lim_{x \rightarrow \infty} (x + 4)^5(x - 3)^4 = \infty$ since both factors are large positive when x is large positive. $\lim_{x \rightarrow -\infty} (x + 4)^5(x - 3)^4 = -\infty$ since the first factor is large negative and the second factor is large positive when x is large negative.

50. $y = (1 - x)(x - 3)^2(x - 5)^2$. As $x \rightarrow \infty$, the first factor approaches $-\infty$ while the second and third factors approach ∞ . Therefore, $\lim_{x \rightarrow \infty} f(x) = -\infty$. As $x \rightarrow -\infty$, the factors all approach ∞ . Therefore, $\lim_{x \rightarrow -\infty} f(x) = \infty$. Now the y -intercept is $f(0) = (1)(-3)^2(-5)^2 = 225$ and the x -intercepts are the solutions to $f(x) = 0 \Rightarrow x = 1, 3$, and 5 . Notice that $f(x)$ does not change sign at $x = 3$ or $x = 5$ because the factors $(x - 3)^2$ and $(x - 5)^2$ are always positive, so the graph does not cross the x -axis at $x = 3$ or $x = 5$, but does cross the x -axis at $x = 1$.

51. First we plot the points which are known to be on the graph: $(2, -1)$ and $(0, 0)$. We can also draw a short line segment of slope 0 at $x = 2$, since we are given that $f'(2) = 0$. Now we know that $f'(x) < 0$ (that is, the function is decreasing) on $(0, 2)$, and that $f''(x) < 0$ on $(0, 1)$ and $f''(x) > 0$ on $(1, 2)$. So we must join the points $(0, 0)$ and $(2, -1)$ in

such a way that the curve is concave down on $(0, 1)$ and concave up on $(1, 2)$. The curve must be concave up and increasing on $(2, 4)$ and concave down and increasing toward $y = 1$ on $(4, \infty)$. Now we just need to reflect the curve in the y -axis, since we are given that f is an even function [the condition that $f(-x) = f(x)$ for all x].

52. The diagram shows one possible function satisfying all of the given conditions.

53. We are given that $f(1) = f'(1) = 0$. So we can draw a short horizontal line at the point $(1, 0)$ to represent this situation. We are given that $x = 0$ and $x = 2$ are vertical asymptotes, with $\lim_{x \rightarrow 0^-} f(x) = -\infty$, $\lim_{x \rightarrow 2^+} f(x) = \infty$ and $\lim_{x \rightarrow 2^-} f(x) = -\infty$, so we can draw the parts of the curve which approach these asymptotes.

On the interval $(-\infty, 0)$, the graph is concave down, and $f(x) \rightarrow \infty$ as $x \rightarrow -\infty$. Between the asymptotes the graph is concave down. On the interval $(2, \infty)$ the graph is concave up, and $f(x) \rightarrow 0$ as $x \rightarrow \infty$, so $y = 0$ is a horizontal asymptote. The diagram shows one possible function satisfying all of the given conditions.

54. The diagram shows one possible function satisfying all of the given conditions.

55. (a) Since $-1 \leq \sin x \leq 1$ for all x , $-\frac{1}{x} \leq \frac{\sin x}{x} \leq \frac{1}{x}$ for $x > 0$. As $x \rightarrow \infty$, $-1/x \rightarrow 0$ and $1/x \rightarrow 0$, so by the Squeeze Theorem, $(\sin x)/x \rightarrow 0$. Thus, $\lim_{x \rightarrow \infty} \frac{\sin x}{x} = 0$.

- (b) From part (a), the horizontal asymptote is $y = 0$. The function $y = (\sin x)/x$ crosses the horizontal asymptote whenever $\sin x = 0$; that is, at $x = \pi n$ for every integer n . Thus, the graph crosses the asymptote an infinite number of times.

56. (a) In both viewing rectangles, $\lim_{x \rightarrow \infty} P(x) = \lim_{x \rightarrow \infty} Q(x) = \infty$ and $\lim_{x \rightarrow -\infty} P(x) = \lim_{x \rightarrow -\infty} Q(x) = -\infty$. In the larger viewing rectangle, P and Q become less distinguishable.

$$(b) \lim_{x \rightarrow \infty} \frac{P(x)}{Q(x)} = \lim_{x \rightarrow \infty} \frac{3x^5 - 5x^3 + 2x}{3x^5} = \lim_{x \rightarrow \infty} \left(1 - \frac{5}{3} \cdot \frac{1}{x^2} + \frac{2}{3} \cdot \frac{1}{x^4} \right) = 1 - \frac{5}{3}(0) + \frac{2}{3}(0) = 1 \Rightarrow$$

P and Q have the same end behavior.

57. Divide the numerator and the denominator by the highest power of x in $Q(x)$.

- (a) If $\deg P < \deg Q$, then the numerator $\rightarrow 0$ but the denominator doesn't. So $\lim_{x \rightarrow \infty} [P(x)/Q(x)] = 0$.
- (b) If $\deg P > \deg Q$, then the numerator $\rightarrow \pm\infty$ but the denominator doesn't, so $\lim_{x \rightarrow \infty} [P(x)/Q(x)] = \pm\infty$ (depending on the ratio of the leading coefficients of P and Q).

58.

(i) $n = 0$

(ii) $n > 0$ (n odd)

(iii) $n > 0$ (n even)

(iv) $n < 0$ (n odd)

(v) $n < 0$ (n even)

From these sketches we see that

$$(a) \lim_{x \rightarrow 0^+} x^n = \begin{cases} 1 & \text{if } n = 0 \\ 0 & \text{if } n > 0 \\ \infty & \text{if } n < 0 \end{cases}$$

$$(b) \lim_{x \rightarrow 0^-} x^n = \begin{cases} 1 & \text{if } n = 0 \\ 0 & \text{if } n > 0 \\ -\infty & \text{if } n < 0, n \text{ odd} \\ \infty & \text{if } n < 0, n \text{ even} \end{cases}$$

$$(c) \lim_{x \rightarrow \infty} x^n = \begin{cases} 1 & \text{if } n = 0 \\ \infty & \text{if } n > 0 \\ 0 & \text{if } n < 0 \end{cases}$$

$$(d) \lim_{x \rightarrow -\infty} x^n = \begin{cases} 1 & \text{if } n = 0 \\ -\infty & \text{if } n > 0, n \text{ odd} \\ \infty & \text{if } n > 0, n \text{ even} \\ 0 & \text{if } n < 0 \end{cases}$$

59. $\lim_{x \rightarrow \infty} \frac{4x-1}{x} = \lim_{x \rightarrow \infty} \left(4 - \frac{1}{x} \right) = 4$, and $\lim_{x \rightarrow \infty} \frac{4x^2+3x}{x^2} = \lim_{x \rightarrow \infty} \left(4 + \frac{3}{x} \right) = 4$. Therefore, by the Squeeze

Theorem, $\lim_{x \rightarrow \infty} f(x) = 4$.

60. (a) After t minutes, $25t$ liters of brine with 30 g of salt per liter has been pumped into the tank, so it contains $(5000 + 25t)$ liters of water and $25t \cdot 30 = 750t$ grams of salt. Therefore, the salt concentration at time t will

$$\text{be } C(t) = \frac{750t}{5000 + 25t} = \frac{30t}{200 + t} \frac{\text{g}}{\text{L}}.$$

- (b) $\lim_{t \rightarrow \infty} C(t) = \lim_{t \rightarrow \infty} \frac{30t}{200 + t} = \lim_{t \rightarrow \infty} \frac{30t/t}{200/t + t/t} = \frac{30}{0 + 1} = 30$. So the salt concentration approaches that of the brine being pumped into the tank.

61. $\left| \frac{6x^2 + 5x - 3}{2x^2 - 1} - 3 \right| < 0.2 \Leftrightarrow 2.8 < \frac{6x^2 + 5x - 3}{2x^2 - 1} < 3.2$. So

we graph the three parts of this inequality on the same screen, and

find that the curve $y = \frac{6x^2 + 5x - 3}{2x^2 - 1}$ seems to lie between the lines

$y = 2.8$ and $y = 3.2$ whenever $x > 12.8$. So we can choose $N = 13$ (or any larger number) so that the inequality holds whenever $x \geq N$.

62. For $\varepsilon = 0.5$, we must find N such that whenever $x \geq N$, we have

$$\left| \frac{\sqrt{4x^2 + 1}}{x + 1} - 2 \right| < 0.5 \Leftrightarrow 1.5 < \frac{\sqrt{4x^2 + 1}}{x + 1} < 2.5.$$

We graph the three parts of this inequality on the same screen, and find that it holds whenever $x \geq 3$. So we choose $N = 3$ (or any larger

number). For $\varepsilon = 0.1$, we must have $1.9 < \frac{\sqrt{4x^2 + 1}}{x + 1} < 2.1$, and

the graphs show that this holds whenever $x \geq 19$. So we choose $N = 19$ (or any larger number).

63. For $\varepsilon = 0.5$, we need to find N such that $\left| \frac{\sqrt{4x^2 + 1}}{x + 1} - (-2) \right| < 0.5$

$$\Leftrightarrow -2.5 < \frac{\sqrt{4x^2 + 1}}{x + 1} < -1.5 \text{ whenever } x \leq N.$$

We graph the three parts of this inequality on the same screen, and see that the inequality holds for $x \leq -6$. So we choose $N = -6$ (or any smaller number).

For $\varepsilon = 0.1$, we need $-2.1 < \frac{\sqrt{4x^2 + 1}}{x + 1} < -1.9$ whenever

$x \leq N$. From the graph, it seems that this inequality holds for $x \leq -22$. So we choose $N = -22$ (or any smaller number).

64. We need N such that $\frac{2x+1}{\sqrt{x+1}} > 100$ whenever $x \geq N$. From the

graph, we see that this inequality holds for $x \geq 2500$. So we choose

$N = 2500$ (or any larger number).

65. (a) $1/x^2 < 0.0001 \Leftrightarrow x^2 > 1/0.0001 = 10,000 \Leftrightarrow x > 100 \quad (x > 0)$

(b) If $\varepsilon > 0$ is given, then $1/x^2 < \varepsilon \Leftrightarrow x^2 > 1/\varepsilon \Leftrightarrow x > 1/\sqrt{\varepsilon}$. Let $N = 1/\sqrt{\varepsilon}$.

$$\text{Then } x > N \Rightarrow x > \frac{1}{\sqrt{\varepsilon}} \Rightarrow \left| \frac{1}{x^2} - 0 \right| = \frac{1}{x^2} < \varepsilon, \text{ so } \lim_{x \rightarrow \infty} \frac{1}{x^2} = 0.$$

66. (a) $1/\sqrt{x} < 0.0001 \Leftrightarrow \sqrt{x} > 1/0.0001 = 10^4 \Leftrightarrow x > 10^8$

(b) If $\varepsilon > 0$ is given, then $1/\sqrt{x} < \varepsilon \Leftrightarrow \sqrt{x} > 1/\varepsilon \Leftrightarrow x > 1/\varepsilon^2$. Let $N = 1/\varepsilon^2$.

$$\text{Then } x > N \Rightarrow x > \frac{1}{\varepsilon^2} \Rightarrow \left| \frac{1}{\sqrt{x}} - 0 \right| = \frac{1}{\sqrt{x}} < \varepsilon, \text{ so } \lim_{x \rightarrow \infty} \frac{1}{\sqrt{x}} = 0.$$

67. For $x < 0$, $|1/x - 0| = -1/x$. If $\varepsilon > 0$ is given, then $-1/x < \varepsilon \Leftrightarrow x < -1/\varepsilon$.

Take $N = -1/\varepsilon$. Then $x < N \Rightarrow x < -1/\varepsilon \Rightarrow |(1/x) - 0| = -1/x < \varepsilon$, so $\lim_{x \rightarrow -\infty} (1/x) = 0$.

68. Given $M > 0$, we need $N > 0$ such that $x > N \Rightarrow x^3 > M$. Now $x^3 > M \Leftrightarrow x > \sqrt[3]{M}$, so take $N = \sqrt[3]{M}$. Then $x > N = \sqrt[3]{M} \Rightarrow x^3 > M$, so $\lim_{x \rightarrow \infty} x^3 = \infty$.

69. Suppose that $\lim_{x \rightarrow \infty} f(x) = L$. Then for every $\varepsilon > 0$ there is a corresponding positive number N such that

$$|f(x) - L| < \varepsilon \text{ whenever } x > N. \text{ If } t = 1/x, \text{ then } x > N \Leftrightarrow 0 < 1/x < 1/N \Leftrightarrow 0 < t < 1/N. \text{ Thus,}$$

for every $\varepsilon > 0$ there is a corresponding $\delta > 0$ (namely $1/N$) such that $|f(1/t) - L| < \varepsilon$ whenever $0 < t < \delta$.

This proves that $\lim_{t \rightarrow 0^+} f(1/t) = L = \lim_{x \rightarrow \infty} f(x)$.

Now suppose that $\lim_{x \rightarrow -\infty} f(x) = L$. Then for every $\varepsilon > 0$ there is a corresponding negative number N such that

$$|f(x) - L| < \varepsilon \text{ whenever } x < N. \text{ If } t = 1/x, \text{ then } x < N \Leftrightarrow 1/N < 1/x < 0 \Leftrightarrow 1/N < t < 0. \text{ Thus, for}$$

every $\varepsilon > 0$ there is a corresponding $\delta > 0$ (namely $-1/N$) such that $|f(1/t) - L| < \varepsilon$ whenever $-\delta < t < 0$.

This proves that $\lim_{t \rightarrow 0^-} f(1/t) = L = \lim_{x \rightarrow -\infty} f(x)$.

70. **Definition** Let f be a function defined on some interval $(-\infty, a)$. Then $\lim_{x \rightarrow -\infty} f(x) = -\infty$ means that for every

negative number M there is a corresponding negative number N such that $f(x) < M$ whenever $x < N$. Now we use the definition to prove that $\lim_{x \rightarrow -\infty} (1 + x^3) = -\infty$. Given a negative number M , we need a negative number

N such that $x < N \Rightarrow 1 + x^3 < M$. Now $1 + x^3 < M \Leftrightarrow x^3 < M - 1 \Leftrightarrow x < \sqrt[3]{M - 1}$. Thus, we

take $N = \sqrt[3]{M - 1}$ and find that $x < N \Rightarrow 1 + x^3 < M$. This proves that $\lim_{x \rightarrow -\infty} (1 + x^3) = -\infty$.

4.5 Summary of Curve Sketching

1. $y = f(x) = x^3 + x = x(x^2 + 1)$ A. f is a polynomial, so $D = \mathbb{R}$.

B. x -intercept = 0, y -intercept = $f(0) = 0$ C. $f(-x) = -f(x)$, so f is odd; the curve is symmetric about the origin. D. f is a polynomial, so there is no asymptote. E. $f'(x) = 3x^2 + 1 > 0$, so f is increasing on $(-\infty, \infty)$. F. There is no critical number and hence, no local maximum or minimum value. G. $f''(x) = 6x > 0$ on $(0, \infty)$ and $f''(x) < 0$ on $(-\infty, 0)$, so f is CU on $(0, \infty)$ and CD on $(-\infty, 0)$. Since the concavity changes at $x = 0$, there is an inflection point at $(0, 0)$.

H.

2. $y = f(x) = x^3 + 6x^2 + 9x = x(x+3)^2$ A. $D = \mathbb{R}$ B. x -intercepts are -3 and 0 , y -intercept = 0 C. No symmetry D. No asymptote

E. $f'(x) = 3x^2 + 12x + 9 = 3(x+1)(x+3) < 0 \Leftrightarrow -3 < x < -1$, so f is decreasing on $(-3, -1)$ and increasing on $(-\infty, -3)$ and $(-1, \infty)$. F. Local maximum value $f(-3) = 0$, local minimum value $f(-1) = -4$ G. $f''(x) = 6x + 12 = 6(x+2) > 0 \Leftrightarrow x > -2$, so f is CU on $(-2, \infty)$ and CD on $(-\infty, -2)$. IP at $(-2, -2)$

H.

3. $y = f(x) = 2 - 15x + 9x^2 - x^3 = -(x-2)(x^2 - 7x + 1)$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 2$; x -intercepts: $f(x) = 0 \Rightarrow x = 2$ or (by the quadratic formula) $x = \frac{7 \pm \sqrt{45}}{2} \approx 0.15, 6.85$

C. No symmetry D. No asymptote

$$\begin{aligned} \text{E. } f'(x) &= -15 + 18x - 3x^2 = -3(x^2 - 6x + 5) \\ &= -3(x-1)(x-5) > 0 \Leftrightarrow 1 < x < 5 \end{aligned}$$

so f is increasing on $(1, 5)$ and decreasing on $(-\infty, 1)$ and $(5, \infty)$.

F. Local maximum value $f(5) = 27$, local minimum value $f(1) = -5$

G. $f''(x) = 18 - 6x = -6(x-3) > 0 \Leftrightarrow x < 3$, so f is CU on $(-\infty, 3)$ and CD on $(3, \infty)$. IP at $(3, 11)$

H.

4. $y = f(x) = 8x^2 - x^4 = x^2(8 - x^2)$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$; x -intercepts: $f(x) = 0 \Rightarrow$

$x = 0, \pm 2\sqrt{2} (\approx \pm 2.83)$ C. $f(-x) = f(x)$, so f is even and symmetric about the y -axis. D. No asymptote

$$\text{E. } f'(x) = 16x - 4x^3 = 4x(4 - x^2) = 4x(2+x)(2-x) > 0 \Leftrightarrow$$

$x < -2$ or $0 < x < 2$, so f is increasing on $(-\infty, -2)$ and $(0, 2)$ and decreasing on $(-2, 0)$ and $(2, \infty)$. F. Local maximum value

$f(\pm 2) = 16$, local minimum value $f(0) = 0$

$$\text{G. } f''(x) = 16 - 12x^2 = 4(4 - 3x^2) = 0 \Leftrightarrow x = \pm \frac{2}{\sqrt{3}}.$$

$f''(x) > 0 \Leftrightarrow -\frac{2}{\sqrt{3}} < x < \frac{2}{\sqrt{3}}$, so f is CU on $(-\frac{2}{\sqrt{3}}, \frac{2}{\sqrt{3}})$ and

CD on $(-\infty, -\frac{2}{\sqrt{3}})$ and $(\frac{2}{\sqrt{3}}, \infty)$. IP at $(\pm \frac{2}{\sqrt{3}}, \frac{80}{9})$

H.

5. $y = f(x) = x^4 + 4x^3 = x^3(x + 4)$ A. $D = \mathbb{R}$ B. y -intercept:

$f(0) = 0$; x -intercepts: $f(x) = 0 \Leftrightarrow x = -4, 0$ C. No symmetry

D. No asymptote E. $f'(x) = 4x^3 + 12x^2 = 4x^2(x + 3) > 0 \Leftrightarrow$

$x > -3$, so f is increasing on $(-3, \infty)$ and decreasing on $(-\infty, -3)$.

F. Local minimum value $f(-3) = -27$, no local maximum

G. $f''(x) = 12x^2 + 24x = 12x(x + 2) < 0 \Leftrightarrow -2 < x < 0$,

so f is CD on $(-2, 0)$ and CU on $(-\infty, -2)$ and $(0, \infty)$.

IP at $(0, 0)$ and $(-2, -16)$

H.

6. $y = f(x) = x(x + 2)^3$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$;

x -intercepts: $f(x) = 0 \Leftrightarrow x = -2, 0$ C. No symmetry D. No asymptote

E. $f'(x) = 3x(x + 2)^2 + (x + 2)^3 = (x + 2)^2 [3x + (x + 2)] = (x + 2)^2 (4x + 2)$. $f'(x) > 0 \Leftrightarrow x > -\frac{1}{2}$,

and $f'(x) < 0 \Leftrightarrow x < -2$ or $-2 < x < -\frac{1}{2}$, so f is increasing on $(-\frac{1}{2}, \infty)$ and decreasing on $(-\infty, -2)$

and $(-2, -\frac{1}{2})$. [Hence f is decreasing on $(-\infty, -\frac{1}{2})$ by the analogue of Exercise 4.3.53 for decreasing functions.]

F. Local minimum value $f(-\frac{1}{2}) = -\frac{27}{16}$, no local maximum

G. $f''(x) = (x + 2)^2(4) + (4x + 2)(2)(x + 2)$

$$= 2(x + 2)[(x + 2)(2) + 4x + 2]$$

$$= 2(x + 2)(6x + 6) = 12(x + 1)(x + 2)$$

$f''(x) < 0 \Leftrightarrow -2 < x < -1$, so f is CD on $(-2, -1)$ and CU on

$(-\infty, -2)$ and $(-1, \infty)$. IP at $(-2, 0)$ and $(-1, -1)$

H.

7. $y = f(x) = 2x^5 - 5x^2 + 1$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 1$ C. No symmetry D. No asymptote

E. $f'(x) = 10x^4 - 10x = 10x(x^3 - 1) = 10x(x - 1)(x^2 + x + 1)$, so $f'(x) < 0 \Leftrightarrow 0 < x < 1$ and

$f'(x) > 0 \Leftrightarrow x < 0$ or $x > 1$. Thus, f is increasing on $(-\infty, 0)$ and $(1, \infty)$ and decreasing on $(0, 1)$.

F. Local maximum value $f(0) = 1$, local minimum value $f(1) = -2$

G. $f''(x) = 40x^3 - 10 = 10(4x^3 - 1)$ so $f''(x) = 0 \Leftrightarrow x = 1/\sqrt[3]{4}$.

$f''(x) > 0 \Leftrightarrow x > 1/\sqrt[3]{4}$ and $f''(x) < 0 \Leftrightarrow x < 1/\sqrt[3]{4}$,

so f is CD on $(-\infty, 1/\sqrt[3]{4})$ and CU on $(1/\sqrt[3]{4}, \infty)$.

IP at $\left(\frac{1}{\sqrt[3]{4}}, 1 - \frac{9}{2(\sqrt[3]{4})^2}\right) \approx (0.630, -0.786)$

H.

8. $y = f(x) = 20x^3 - 3x^5$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$; x -intercepts: $f(x) = 0 \Leftrightarrow$

$$-3x^3(x^2 - \frac{20}{3}) = 0 \Leftrightarrow x = 0 \text{ or } \pm\sqrt{20/3} \approx \pm 2.582 \quad \text{C. } f(-x) = -f(x), \text{ so } f \text{ is odd;}$$

the curve is symmetric about the origin. D. No asymptote

E. $f'(x) = 60x^2 - 15x^4 = -15x^2(x^2 - 4) = -15x^2(x+2)(x-2)$, so $f'(x) > 0 \Leftrightarrow -2 < x < 0$ or

$0 < x < 2$ and $f'(x) < 0 \Leftrightarrow x < -2$ or $x > 2$. Thus, f is increasing on $(-2, 0)$ and $(0, 2)$ [hence on $(-2, 2)$ by Exercise 4.3.53] and f is decreasing on $(-\infty, -2)$ and $(2, \infty)$.

F. Local minimum value $f(-2) = -64$, local maximum

value $f(2) = 64$ G. $f''(x) = 120x - 60x^3 = -60x(x^2 - 2)$.

$$f''(x) > 0 \Leftrightarrow x < -\sqrt{2} \text{ or } 0 < x < \sqrt{2}; f''(x) < 0 \Leftrightarrow$$

$$-\sqrt{2} < x < 0 \text{ or } x > \sqrt{2}. \text{ Thus, } f \text{ is CU on } (-\infty, -\sqrt{2})$$

and $(0, \sqrt{2})$, and f is CD on $(-\sqrt{2}, 0)$ and $(\sqrt{2}, \infty)$. IP at

$$(-\sqrt{2}, -28\sqrt{2}) \approx (-1.414, -39.598), (0, 0), \text{ and } (\sqrt{2}, 28\sqrt{2})$$

9. $y = f(x) = x/(x-1)$ A. $D = \{x \mid x \neq 1\} = (-\infty, 1) \cup (1, \infty)$ B. x -intercept = 0,

y -intercept = $f(0) = 0$ C. No symmetry D. $\lim_{x \rightarrow \pm\infty} \frac{x}{x-1} = 1$, so $y = 1$ is a HA.

$$\lim_{x \rightarrow 1^-} \frac{x}{x-1} = -\infty, \lim_{x \rightarrow 1^+} \frac{x}{x-1} = \infty, \text{ so } x = 1 \text{ is a VA.}$$

E. $f'(x) = \frac{(x-1) - x}{(x-1)^2} = \frac{-1}{(x-1)^2} < 0$ for $x \neq 1$, so f is decreasing

on $(-\infty, 1)$ and $(1, \infty)$. F. No extreme values

G. $f''(x) = \frac{2}{(x-1)^3} > 0 \Leftrightarrow x > 1$, so f is CU on $(1, \infty)$ and CD

on $(-\infty, 1)$. No IP

10. $y = x/(x-1)^2$ A. $D = \{x \mid x \neq 1\} = (-\infty, 1) \cup (1, \infty)$ B. x -intercept = 0, y -intercept = $f(0) = 0$

C. No symmetry D. $\lim_{x \rightarrow \pm\infty} \frac{x}{(x-1)^2} = 0$, so $y = 0$ is a HA. $\lim_{x \rightarrow 1} \frac{x}{(x-1)^2} = \infty$, so $x = 1$ is a VA.

E. $f'(x) = \frac{(x-1)^2(1) - x(2)(x-1)}{(x-1)^4} = \frac{-x-1}{(x-1)^3}$. This is negative on $(-\infty, -1)$ and $(1, \infty)$ and positive on

$(-1, 1)$, so $f(x)$ is decreasing on $(-\infty, -1)$ and $(1, \infty)$ and increasing on $(-1, 1)$.

F. Local minimum value $f(-1) = -\frac{1}{4}$, no local maximum.

G. $f''(x) = \frac{(x-1)^3(-1) + (x+1)(3)(x-1)^2}{(x-1)^6} = \frac{2(x+2)}{(x-1)^4}$. This is

negative on $(-\infty, -2)$, and positive on $(-2, 1)$ and $(1, \infty)$. So f is CD

on $(-\infty, -2)$ and CU on $(-2, 1)$ and $(1, \infty)$. IP at $(-2, -\frac{2}{9})$

11. $y = f(x) = 1/(x^2 - 9)$ A. $D = \{x \mid x \neq \pm 3\} = (-\infty, -3) \cup (-3, 3) \cup (3, \infty)$

B. y -intercept $= f(0) = -\frac{1}{9}$, no x -intercept C. $f(-x) = f(x) \Rightarrow f$ is even; the curve is symmetric about

the y -axis. D. $\lim_{x \rightarrow \pm\infty} \frac{1}{x^2 - 9} = 0$, so $y = 0$ is a HA. $\lim_{x \rightarrow 3^-} \frac{1}{x^2 - 9} = -\infty$, $\lim_{x \rightarrow 3^+} \frac{1}{x^2 - 9} = \infty$,

$\lim_{x \rightarrow -3^-} \frac{1}{x^2 - 9} = \infty$, $\lim_{x \rightarrow -3^+} \frac{1}{x^2 - 9} = -\infty$, so $x = 3$ and $x = -3$ are VA.

E. $f'(x) = -\frac{2x}{(x^2 - 9)^2} > 0 \Leftrightarrow x < 0$ ($x \neq -3$) so f is increasing

on $(-\infty, -3)$ and $(-3, 0)$ and decreasing on $(0, 3)$ and $(3, \infty)$.

F. Local maximum value $f(0) = -\frac{1}{9}$.

G. $y'' = \frac{-2(x^2 - 9)^2 + (2x)2(x^2 - 9)(2x)}{(x^2 - 9)^4} = \frac{6(x^2 + 3)}{(x^2 - 9)^3} > 0 \Leftrightarrow$

$x^2 > 9 \Leftrightarrow x > 3$ or $x < -3$, so f is CU on $(-\infty, -3)$ and $(3, \infty)$

and CD on $(-3, 3)$. No IP

12. $y = f(x) = x/(x^2 - 9)$ A. $D = \{x \mid x \neq \pm 3\} = (-\infty, -3) \cup (-3, 3) \cup (3, \infty)$ B. x -intercept $= 0$,

y -intercept $= f(0) = 0$. C. $f(-x) = -f(x)$, so f is odd; the curve is symmetric about the origin.

D. $\lim_{x \rightarrow \pm\infty} \frac{x}{x^2 - 9} = 0$, so $y = 0$ is a HA. $\lim_{x \rightarrow 3^+} \frac{x}{x^2 - 9} = \infty$, $\lim_{x \rightarrow 3^-} \frac{x}{x^2 - 9} = -\infty$,

$\lim_{x \rightarrow -3^+} \frac{x}{x^2 - 9} = \infty$, $\lim_{x \rightarrow -3^-} \frac{x}{x^2 - 9} = -\infty$, so $x = 3$ and $x = -3$ are VA.

E. $f'(x) = \frac{(x^2 - 9) - x(2x)}{(x^2 - 9)^2} = -\frac{x^2 + 9}{(x^2 - 9)^2} < 0$ ($x \neq \pm 3$) so f is decreasing on $(-\infty, -3)$, $(-3, 3)$,

and $(3, \infty)$. F. No extreme values

G. $f''(x) = -\frac{2x(x^2 - 9)^2 - (x^2 + 9) \cdot 2(x^2 - 9)(2x)}{(x^2 - 9)^4}$

$= \frac{2x(x^2 + 27)}{(x^2 - 9)^3} > 0$ when $-3 < x < 0$ or $x > 3$,

so f is CU on $(-3, 0)$ and $(3, \infty)$; CD on $(-\infty, -3)$ and $(0, 3)$.

IP at $(0, 0)$

13. $y = f(x) = x/(x^2 + 9)$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$; x -intercept: $f(x) = 0 \Leftrightarrow x = 0$

C. $f(-x) = -f(x)$, so f is odd and the curve is symmetric about the origin. D. $\lim_{x \rightarrow \pm\infty} [x/(x^2 + 9)] = 0$, so

$y = 0$ is a HA; no VA E. $f'(x) = \frac{(x^2 + 9)(1) - x(2x)}{(x^2 + 9)^2} = \frac{9 - x^2}{(x^2 + 9)^2} = \frac{(3 + x)(3 - x)}{(x^2 + 9)^2} > 0 \Leftrightarrow$

$-3 < x < 3$, so f is increasing on $(-3, 3)$ and decreasing on $(-\infty, -3)$ and $(3, \infty)$.

F. Local minimum value $f(-3) = -\frac{1}{6}$, local maximum value $f(3) = \frac{1}{6}$

$$\begin{aligned} \text{G. } f''(x) &= \frac{(x^2 + 9)^2(-2x) - (9 - x^2) \cdot 2(x^2 + 9)(2x)}{[(x^2 + 9)^2]^2} \\ &= \frac{(2x)(x^2 + 9)[-(x^2 + 9) - 2(9 - x^2)]}{(x^2 + 9)^4} \\ &= \frac{2x(x^2 - 27)}{(x^2 + 9)^3} = 0 \Leftrightarrow x = 0, \pm\sqrt{27} = \pm 3\sqrt{3} \end{aligned}$$

$f''(x) > 0 \Leftrightarrow -3\sqrt{3} < x < 0$ or $x > 3\sqrt{3}$, so f is CU on

$(-3\sqrt{3}, 0)$ and $(3\sqrt{3}, \infty)$, and CD on $(-\infty, -3\sqrt{3})$ and $(0, 3\sqrt{3})$.

There are three inflection points: $(0, 0)$ and $(\pm 3\sqrt{3}, \pm \frac{1}{12}\sqrt{3})$.

14. $y = f(x) = x^2/(x^2 + 9)$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$; x -intercept: $f(x) = 0 \Leftrightarrow x = 0$

C. $f(-x) = f(x)$, so f is even and symmetric about the y -axis. D. $\lim_{x \rightarrow \pm\infty} [x^2/(x^2 + 9)] = 1$, so $y = 1$

is a HA; no VA E. $f'(x) = \frac{(x^2 + 9)(2x) - x^2(2x)}{(x^2 + 9)^2} = \frac{18x}{(x^2 + 9)^2} > 0 \Leftrightarrow x > 0$, so f is increasing on

$(0, \infty)$ and decreasing on $(-\infty, 0)$. F. Local minimum value $f(0) = 0$; no local maximum

$$\begin{aligned} \text{G. } f''(x) &= \frac{(x^2 + 9)^2(18) - 18x \cdot 2(x^2 + 9) \cdot 2x}{[(x^2 + 9)^2]^2} = \frac{18(x^2 + 9)[(x^2 + 9) - 4x^2]}{(x^2 + 9)^4} = \frac{18(9 - 3x^2)}{(x^2 + 9)^3} \\ &= \frac{-54(x + \sqrt{3})(x - \sqrt{3})}{(x^2 + 9)^3} > 0 \Leftrightarrow -\sqrt{3} < x < \sqrt{3} \end{aligned}$$

so f is CU on $(-\sqrt{3}, \sqrt{3})$ and CD on $(-\infty, -\sqrt{3})$ and $(\sqrt{3}, \infty)$.

There are two inflection points: $(\pm\sqrt{3}, \frac{1}{4})$.

H.

H.

15. $y = f(x) = \frac{x-1}{x^2}$ A. $D = \{x \mid x \neq 0\} = (-\infty, 0) \cup (0, \infty)$ B. No y -intercept; x -intercept: $f(x) = 0 \Leftrightarrow$

$x = 1$ C. No symmetry D. $\lim_{x \rightarrow \pm\infty} \frac{x-1}{x^2} = 0$, so $y = 0$ is a HA. $\lim_{x \rightarrow 0} \frac{x-1}{x^2} = -\infty$, so $x = 0$ is a VA.

$$\text{E. } f'(x) = \frac{x^2 \cdot 1 - (x-1) \cdot 2x}{(x^2)^2} = \frac{-x^2 + 2x}{x^4} = \frac{-(x-2)}{x^3}, \text{ so } f'(x) > 0 \Leftrightarrow 0 < x < 2 \text{ and}$$

$f'(x) < 0 \Leftrightarrow x < 0$ or $x > 2$. Thus, f is increasing on $(0, 2)$ and decreasing on $(-\infty, 0)$ and $(2, \infty)$.

F. No local minimum, local maximum value $f(2) = \frac{1}{4}$.

$$\text{G. } f''(x) = \frac{x^3 \cdot (-1) - [-(x-2)] \cdot 3x^2}{(x^3)^2} = \frac{2x^3 - 6x^2}{x^6} = \frac{2(x-3)}{x^4}.$$

$f''(x)$ is negative on $(-\infty, 0)$ and $(0, 3)$ and positive on $(3, \infty)$, so f is

CD on $(-\infty, 0)$ and $(0, 3)$ and CU on $(3, \infty)$. IP at $(3, \frac{2}{9})$

H.

16. $y = f(x) = \frac{x^2 - 2}{x^4}$ A. $D = \{x \mid x \neq 0\} = (-\infty, 0) \cup (0, \infty)$ B. No y -intercept; x -intercepts: $f(x) = 0$

$\Leftrightarrow x = \pm\sqrt{2}$ C. $f(-x) = f(x)$, so f is even; the curve is symmetric about the y -axis.

D. $\lim_{x \rightarrow \pm\infty} \frac{x^2 - 2}{x^4} = 0$, so $y = 0$ is a HA. $\lim_{x \rightarrow 0} \frac{x^2 - 2}{x^4} = -\infty$, so $x = 0$ is a VA.

E. $f'(x) = \frac{x^4 \cdot 2x - (x^2 - 2)(4x^3)}{(x^4)^2} = \frac{-2x^5 + 8x^3}{x^8} = \frac{-2(x^2 - 4)}{x^5} = \frac{-2(x+2)(x-2)}{x^5}$.

$f'(x)$ is negative on $(-2, 0)$ and $(2, \infty)$ and positive on $(-\infty, -2)$ and $(0, 2)$, so f is decreasing on $(-2, 0)$ and $(2, \infty)$ and increasing on $(-\infty, -2)$ and $(0, 2)$. F. Local maximum value $f(\pm 2) = \frac{1}{8}$, no local minimum.

G. $f''(x) = \frac{x^5 \cdot (-4x) + 2(x^2 - 4) \cdot 5x^4}{(x^5)^2} = \frac{2x^4[-2x^2 + 5(x^2 - 4)]}{x^{10}} = \frac{2(3x^2 - 20)}{x^6}$

$f''(x)$ is positive on $(-\infty, -\sqrt{\frac{20}{3}})$ and $(\sqrt{\frac{20}{3}}, \infty)$ and negative on

$(-\sqrt{\frac{20}{3}}, 0)$ and $(0, \sqrt{\frac{20}{3}})$, so f is CU on $(-\infty, -\sqrt{\frac{20}{3}})$ and

$(\sqrt{\frac{20}{3}}, \infty)$ and CD on $(-\sqrt{\frac{20}{3}}, 0)$ and $(0, \sqrt{\frac{20}{3}})$.

IP at $(\pm\sqrt{\frac{20}{3}}, \frac{21}{200}) \approx (\pm 2.5820, 0.105)$

17. $y = f(x) = \frac{x^2}{x^2 + 3} = \frac{(x^2 + 3) - 3}{x^2 + 3} = 1 - \frac{3}{x^2 + 3}$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$; x -intercepts:

$f(x) = 0 \Leftrightarrow x = 0$ C. $f(-x) = f(x)$, so f is even; the graph is symmetric about the y -axis.

D. $\lim_{x \rightarrow \pm\infty} \frac{x^2}{x^2 + 3} = 1$, so $y = 1$ is a HA. No VA. E. Using the Reciprocal Rule,

$f'(x) = -3 \cdot \frac{-2x}{(x^2 + 3)^2} = \frac{6x}{(x^2 + 3)^2}$. $f'(x) > 0 \Leftrightarrow x > 0$ and $f'(x) < 0 \Leftrightarrow x < 0$, so f is decreasing

on $(-\infty, 0)$ and increasing on $(0, \infty)$. F. Local minimum value $f(0) = 0$, no local maximum.

G. $f''(x) = \frac{(x^2 + 3)^2 \cdot 6 - 6x \cdot 2(x^2 + 3) \cdot 2x}{[(x^2 + 3)^2]^2}$
 $= \frac{6(x^2 + 3)[(x^2 + 3) - 4x^2]}{(x^2 + 3)^4}$
 $= \frac{6(3 - 3x^2)}{(x^2 + 3)^3} = \frac{-18(x+1)(x-1)}{(x^2 + 3)^3}$

$f''(x)$ is negative on $(-\infty, -1)$ and $(1, \infty)$ and positive on $(-1, 1)$, so f is CD on $(-\infty, -1)$ and $(1, \infty)$ and CU on $(-1, 1)$. IP at $(\pm 1, \frac{1}{4})$

18. $y = f(x) = \frac{x^3 - 1}{x^3 + 1}$ A. $D = \{x \mid x \neq -1\} = (-\infty, -1) \cup (-1, \infty)$ B. x -intercept = 1,

y -intercept = $f(0) = -1$ C. No symmetry D. $\lim_{x \rightarrow \pm\infty} \frac{x^3 - 1}{x^3 + 1} = \lim_{x \rightarrow \pm\infty} \frac{1 - 1/x^3}{1 + 1/x^3} = 1$, so $y = 1$ is a HA.

$\lim_{x \rightarrow -1^-} \frac{x^3 - 1}{x^3 + 1} = \infty$ and $\lim_{x \rightarrow -1^+} \frac{x^3 - 1}{x^3 + 1} = -\infty$, so $x = -1$ is a VA.

E. $f'(x) = \frac{(x^3 + 1)(3x^2) - (x^3 - 1)(3x^2)}{(x^3 + 1)^2} = \frac{6x^2}{(x^3 + 1)^2} > 0$ ($x \neq -1$) so f is increasing on $(-\infty, -1)$

and $(-1, \infty)$. F. No extreme values

G. $y'' = \frac{12x(x^3 + 1)^2 - 6x^2 \cdot 2(x^3 + 1) \cdot 3x^2}{(x^3 + 1)^4}$
 $= \frac{12x(1 - 2x^3)}{(x^3 + 1)^3} > 0 \Leftrightarrow x < -1$ or $0 < x < \frac{1}{\sqrt[3]{2}}$,

so f is CU on $(-\infty, -1)$ and $(0, \frac{1}{\sqrt[3]{2}})$ and CD on $(-1, 0)$ and $(\frac{1}{\sqrt[3]{2}}, \infty)$.

IP at $(0, -1)$, $(\frac{1}{\sqrt[3]{2}}, -\frac{1}{3})$

19. $y = f(x) = x\sqrt{5-x}$ A. The domain is $\{x \mid 5 - x \geq 0\} = (-\infty, 5]$ B. y -intercept: $f(0) = 0$;

x -intercepts: $f(x) = 0 \Leftrightarrow x = 0, 5$ C. No symmetry D. No asymptote

E. $f'(x) = x \cdot \frac{1}{2}(5-x)^{-1/2}(-1) + (5-x)^{1/2} \cdot 1 = \frac{1}{2}(5-x)^{-1/2}[-x + 2(5-x)] = \frac{10-3x}{2\sqrt{5-x}} > 0 \Leftrightarrow$

$x < \frac{10}{3}$, so f is increasing on $(-\infty, \frac{10}{3})$ and decreasing on $(\frac{10}{3}, 5)$.

F. Local maximum value $f(\frac{10}{3}) = \frac{10}{9}\sqrt{15} \approx 4.3$; no local minimum

G. $f''(x) = \frac{2(5-x)^{1/2}(-3) - (10-3x) \cdot 2(\frac{1}{2})(5-x)^{-1/2}(-1)}{(2\sqrt{5-x})^2}$
 $= \frac{(5-x)^{-1/2}[-6(5-x) + (10-3x)]}{4(5-x)} = \frac{3x-20}{4(5-x)^{3/2}}$

$f''(x) < 0$ for $x < 5$, so f is CD on $(-\infty, 5)$. No IP

20. $y = f(x) = 2\sqrt{x} - x$ A. $D = [0, \infty)$ B. y -intercept: $f(0) = 0$; x -intercepts: $f(x) = 0 \Rightarrow$

$2\sqrt{x} = x \Rightarrow 4x = x^2 \Rightarrow 4x - x^2 = 0 \Rightarrow x(4-x) = 0 \Rightarrow x = 0, 4$ C. No symmetry

D. No asymptote E. $f'(x) = \frac{1}{\sqrt{x}} - 1 = \frac{1}{\sqrt{x}}(1 - \sqrt{x})$. This is positive for $x < 1$ and

negative for $x > 1$, so f is increasing on $(0, 1)$ and decreasing on $(1, \infty)$.

F. Local maximum value $f(1) = 1$, no local minimum.

G. $f''(x) = (x^{-1/2} - 1)' = -\frac{1}{2}x^{-3/2} = \frac{-1}{2x^{3/2}} < 0$ for $x > 0$,

so f is CD on $(0, \infty)$. No IP

21. $y = f(x) = \sqrt{x^2 + 1} - x$ A. $D = \mathbb{R}$ B. No x -intercept, y -intercept = 1 C. No symmetry

D. $\lim_{x \rightarrow -\infty} (\sqrt{x^2 + 1} - x) = \infty$ and

$$\lim_{x \rightarrow \infty} (\sqrt{x^2 + 1} - x) = \lim_{x \rightarrow \infty} (\sqrt{x^2 + 1} - x) \frac{\sqrt{x^2 + 1} + x}{\sqrt{x^2 + 1} + x} = \lim_{x \rightarrow \infty} \frac{1}{\sqrt{x^2 + 1} + x} = 0,$$

so $y = 0$ is a HA. E. $f'(x) = \frac{x}{\sqrt{x^2 + 1}} - 1 = \frac{x - \sqrt{x^2 + 1}}{\sqrt{x^2 + 1}} \Rightarrow$

$f'(x) < 0$, so f is decreasing on $\mathbb{R}$. F. No extreme values

G. $f''(x) = \frac{1}{(x^2 + 1)^{3/2}} > 0$, so f is CU on $\mathbb{R}$. No IP

22. $y = f(x) = \sqrt{x/(x-5)}$ A. $D = \{x \mid x/(x-5) \geq 0\} = (-\infty, 0] \cup (5, \infty)$. B. Intercepts are 0.

C. No symmetry D. $\lim_{x \rightarrow \pm\infty} \sqrt{\frac{x}{x-5}} = \lim_{x \rightarrow \pm\infty} \sqrt{\frac{1}{1-5/x}} = 1$, so $y = 1$ is a HA. $\lim_{x \rightarrow 5^+} \sqrt{\frac{x}{x-5}} = \infty$,

so $x = 5$ is a VA. E. $f'(x) = \frac{1}{2} \left(\frac{x}{x-5} \right)^{-1/2} \cdot \frac{(-5)}{(x-5)^2} = -\frac{5}{2} [x(x-5)^3]^{-1/2} < 0$, so f is decreasing on

$(-\infty, 0)$ and $(5, \infty)$. F. No extreme values

G. $f''(x) = \frac{5}{4} [x(x-5)^3]^{-3/2} (x-5)^2 (4x-5) > 0$ for $x > 5$, and

$f''(x) < 0$ for $x < 0$, so f is CU on $(5, \infty)$ and CD on $(-\infty, 0)$. No IP

23. $y = f(x) = x/\sqrt{x^2 + 1}$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$; x -intercepts: $f(x) = 0 \Rightarrow x = 0$

C. $f(-x) = -f(x)$, so f is odd; the graph is symmetric about the origin.

$$\begin{aligned} \text{D. } \lim_{x \rightarrow \infty} f(x) &= \lim_{x \rightarrow \infty} \frac{x}{\sqrt{x^2 + 1}} = \lim_{x \rightarrow \infty} \frac{x/x}{\sqrt{x^2 + 1}/x} = \lim_{x \rightarrow \infty} \frac{x/x}{\sqrt{x^2 + 1}/\sqrt{x^2}} = \lim_{x \rightarrow \infty} \frac{1}{\sqrt{1 + 1/x^2}} \\ &= \frac{1}{\sqrt{1 + 0}} = 1 \end{aligned}$$

and

$$\begin{aligned} \lim_{x \rightarrow -\infty} f(x) &= \lim_{x \rightarrow -\infty} \frac{x}{\sqrt{x^2 + 1}} = \lim_{x \rightarrow -\infty} \frac{x/x}{\sqrt{x^2 + 1}/x} = \lim_{x \rightarrow -\infty} \frac{x/x}{\sqrt{x^2 + 1}/(-\sqrt{x^2})} \\ &= \lim_{x \rightarrow -\infty} \frac{1}{-\sqrt{1 + 1/x^2}} = \frac{1}{-\sqrt{1 + 0}} = -1 \end{aligned}$$

so $y = \pm 1$ are HA. No VA.

E. $f'(x) = \frac{\sqrt{x^2 + 1} - x \cdot \frac{2x}{2\sqrt{x^2 + 1}}}{[(x^2 + 1)^{1/2}]^2} = \frac{x^2 + 1 - x^2}{(x^2 + 1)^{3/2}} = \frac{1}{(x^2 + 1)^{3/2}} > 0$ for all x , so f is increasing on $\mathbb{R}$.

F. No extreme values

$$G. f''(x) = -\frac{3}{2}(x^2 + 1)^{-5/2} \cdot 2x = \frac{-3x}{(x^2 + 1)^{5/2}}, \text{ so } f''(x) > 0 \text{ for}$$

 $x < 0 \text{ and } f''(x) < 0 \text{ for } x > 0. \text{ Thus, } f \text{ is CU on } (-\infty, 0) \text{ and}$
CD on $(0, \infty)$. IP at $(0, 0)$

$$24. y = f(x) = x\sqrt{2-x^2} \quad A. D = [-\sqrt{2}, \sqrt{2}] \quad B. y\text{-intercept: } f(0) = 0; x\text{-intercepts: } f(x) = 0 \Rightarrow$$

 $x = 0, \pm\sqrt{2}. \quad C. f(-x) = -f(x), \text{ so } f \text{ is odd; the graph is symmetric about the origin.} \quad D. \text{ No asymptote}$

$$E. f'(x) = x \cdot \frac{-x}{\sqrt{2-x^2}} + \sqrt{2-x^2} = \frac{-x^2 + 2 - x^2}{\sqrt{2-x^2}} = \frac{2(1+x)(1-x)}{\sqrt{2-x^2}}. f'(x) \text{ is negative for}$$

 $-\sqrt{2} < x < -1 \text{ and } 1 < x < \sqrt{2}, \text{ and positive for } -1 < x < 1, \text{ so } f \text{ is decreasing on } (-\sqrt{2}, -1) \text{ and } (1, \sqrt{2})$
and increasing on $(-1, 1)$. F. Local minimum value $f(-1) = -1$, local maximum value $f(1) = 1$.

$$G. f''(x) = \frac{\sqrt{2-x^2}(-4x) - (2-2x^2)\frac{-x}{\sqrt{2-x^2}}}{[(2-x^2)^{1/2}]^2}$$

$$= \frac{(2-x^2)(-4x) + (2-2x^2)x}{(2-x^2)^{3/2}}$$

$$= \frac{2x^3 - 6x}{(2-x^2)^{3/2}} = \frac{2x(x^2 - 3)}{(2-x^2)^{3/2}}$$

Since $x^2 - 3 < 0$ for x in $[-\sqrt{2}, \sqrt{2}]$, $f''(x) > 0$ for $-\sqrt{2} < x < 0$ and $f''(x) < 0$ for $0 < x < \sqrt{2}$. Thus, f is CU on $(-\sqrt{2}, 0)$ and CD on $(0, \sqrt{2})$. The only IP is $(0, 0)$.

$$25. y = f(x) = \sqrt{1-x^2}/x \quad A. D = \left\{ x \mid |x| \leq 1, x \neq 0 \right\} = [-1, 0) \cup (0, 1] \quad B. x\text{-intercepts } \pm 1, \text{ no } y\text{-intercept}$$

$$C. f(-x) = -f(x), \text{ so the curve is symmetric about } (0, 0). \quad D. \lim_{x \rightarrow 0^+} \frac{\sqrt{1-x^2}}{x} = \infty, \lim_{x \rightarrow 0^-} \frac{\sqrt{1-x^2}}{x} = -\infty,$$

$$\text{so } x = 0 \text{ is a VA.} \quad E. f'(x) = \frac{(-x^2/\sqrt{1-x^2}) - \sqrt{1-x^2}}{x^2} = -\frac{1}{x^2\sqrt{1-x^2}} < 0, \text{ so } f \text{ is decreasing on } (-1, 0)$$

and $(0, 1)$. F. No extreme values

$$G. f''(x) = \frac{2-3x^2}{x^3(1-x^2)^{3/2}} > 0 \Leftrightarrow -1 < x < -\sqrt{\frac{2}{3}} \text{ or}$$

 $0 < x < \sqrt{\frac{2}{3}}, \text{ so } f \text{ is CU on } (-1, -\sqrt{\frac{2}{3}}) \text{ and } (0, \sqrt{\frac{2}{3}}) \text{ and CD on}$
 $(-\sqrt{\frac{2}{3}}, 0) \text{ and } (\sqrt{\frac{2}{3}}, 1). \text{ IP at } (\pm\sqrt{\frac{2}{3}}, \pm\frac{1}{\sqrt{2}})$

26. $y = f(x) = x/\sqrt{x^2 - 1}$ A. $D = (-\infty, -1) \cup (1, \infty)$ B. No intercepts C. $f(-x) = -f(x)$, so f is odd; the graph is symmetric about the origin. D. $\lim_{x \rightarrow \infty} \frac{x}{\sqrt{x^2 - 1}} = 1$ and $\lim_{x \rightarrow -\infty} \frac{x}{\sqrt{x^2 - 1}} = -1$, so $y = \pm 1$ are HA.

$\lim_{x \rightarrow 1^+} f(x) = +\infty$ and $\lim_{x \rightarrow -1^-} f(x) = -\infty$, so $x = \pm 1$ are VA.

E. $f'(x) = \frac{\sqrt{x^2 - 1} - x \cdot \frac{x}{\sqrt{x^2 - 1}}}{[(x^2 - 1)^{1/2}]^2} = \frac{x^2 - 1 - x^2}{(x^2 - 1)^{3/2}} = \frac{-1}{(x^2 - 1)^{3/2}} < 0$, so f is decreasing

on $(-\infty, -1)$ and $(1, \infty)$. F. No extreme values

G. $f''(x) = (-1)(-\frac{3}{2})(x^2 - 1)^{-5/2} \cdot 2x = \frac{3x}{(x^2 - 1)^{5/2}}$.

$f''(x) < 0$ on $(-\infty, -1)$ and $f''(x) > 0$ on $(1, \infty)$, so f is CD on $(-\infty, -1)$ and CU on $(1, \infty)$. No IP

27. $y = f(x) = x - 3x^{1/3}$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$; x -intercepts: $f(x) = 0 \Rightarrow x = 3x^{1/3} \Rightarrow x^3 = 27x \Rightarrow x^3 - 27x = 0 \Rightarrow x(x^2 - 27) = 0 \Rightarrow x = 0, \pm 3\sqrt{3}$ C. $f(-x) = -f(x)$, so f is odd;

the graph is symmetric about the origin. D. No asymptote E. $f'(x) = 1 - x^{-2/3} = 1 - \frac{1}{x^{2/3}} = \frac{x^{2/3} - 1}{x^{2/3}}$.

$f'(x) > 0$ when $|x| > 1$ and $f'(x) < 0$ when $0 < |x| < 1$, so f is increasing on $(-\infty, -1)$ and $(1, \infty)$, and decreasing on $(-1, 0)$ and $(0, 1)$ [hence decreasing on $(-1, 1)$ since f is

continuous on $(-1, 1)$]. F. Local maximum value $f(-1) = 2$, local

minimum value $f(1) = -2$ G. $f''(x) = \frac{2}{3}x^{-5/3} < 0$ when $x < 0$

and $f''(x) > 0$ when $x > 0$, so f is CD on $(-\infty, 0)$ and CU on $(0, \infty)$.

IP at $(0, 0)$

28. $y = f(x) = x^{5/3} - 5x^{2/3} = x^{2/3}(x - 5)$ A. $D = \mathbb{R}$ B. x -intercepts 0, 5; y -intercept 0 C. No symmetry

D. $\lim_{x \rightarrow \pm\infty} x^{2/3}(x - 5) = \pm\infty$, so there is no asymptote

E. $f'(x) = \frac{5}{3}x^{2/3} - \frac{10}{3}x^{-1/3} = \frac{5}{3}x^{-1/3}(x - 2) > 0 \Leftrightarrow x < 0$ or $x > 2$, so f is increasing on $(-\infty, 0)$, $(2, \infty)$ and decreasing on $(0, 2)$.

F. Local maximum value $f(0) = 0$, local minimum value $f(2) = -3\sqrt[3]{4}$

G. $f''(x) = \frac{10}{9}x^{-1/3} + \frac{10}{9}x^{-4/3} = \frac{10}{9}x^{-4/3}(x + 1) > 0 \Leftrightarrow$

$x > -1$, so f is CU on $(-1, 0)$ and $(0, \infty)$, CD on $(-\infty, -1)$.

IP at $(-1, -6)$

29. $y = f(x) = x + \sqrt{|x|}$ A. $D = \mathbb{R}$ B. x -intercepts 0, -1; y -intercept 0 C. No symmetry

D. $\lim_{x \rightarrow \infty} (x + \sqrt{|x|}) = \infty$, $\lim_{x \rightarrow -\infty} (x + \sqrt{|x|}) = -\infty$. No asymptote E. For $x > 0$, $f(x) = x + \sqrt{x} \Rightarrow f'(x) = 1 + \frac{1}{2\sqrt{x}} > 0$, so f increases on $(0, \infty)$. For $x < 0$, $f(x) = x + \sqrt{-x} \Rightarrow f'(x) = 1 - \frac{1}{2\sqrt{-x}} > 0$

$\Leftrightarrow 2\sqrt{-x} > 1 \Leftrightarrow -x > \frac{1}{4} \Leftrightarrow x < -\frac{1}{4}$, so f increases on $(-\infty, -\frac{1}{4})$ and decreases on $(-\frac{1}{4}, 0)$.

F. Local maximum value $f(-\frac{1}{4}) = \frac{1}{4}$, local minimum value $f(0) = 0$

H.

G. For $x > 0$, $f''(x) = -\frac{1}{4}x^{-3/2} \Rightarrow f''(x) < 0$, so f is CD on

$(0, \infty)$. For $x < 0$, $f''(x) = -\frac{1}{4}(-x)^{-3/2} \Rightarrow f''(x) < 0$, so f is

CD on $(-\infty, 0)$. No IP

30. $y = f(x) = \sqrt[3]{(x^2 - 1)^2} = (x^2 - 1)^{2/3}$ A. $D = \mathbb{R}$ B. x -intercepts ± 1 , y -intercept 1 C. $f(-x) = f(x)$, so

the curve is symmetric about the y -axis. D. $\lim_{x \rightarrow \pm\infty} (x^2 - 1)^{2/3} = \infty$, no asymptote

E. $f'(x) = \frac{4}{3}x(x^2 - 1)^{-1/3} \Rightarrow f'(x) > 0 \Leftrightarrow x > 1$ or $-1 < x < 0$, $f'(x) < 0 \Leftrightarrow x < -1$ or

$0 < x < 1$. So f is increasing on $(-1, 0)$, $(1, \infty)$ and decreasing on $(-\infty, -1)$, $(0, 1)$. F. Local minimum

values $f(-1) = f(1) = 0$, local maximum value $f(0) = 1$

H.

G. $f''(x) = \frac{4}{3}(x^2 - 1)^{-1/3} + \frac{4}{3}x(-\frac{1}{3})(x^2 - 1)^{-4/3}(2x)$
 $= \frac{4}{9}(x^2 - 3)(x^2 - 1)^{-4/3} > 0 \Leftrightarrow |x| > \sqrt{3}$

so f is CU on $(-\infty, -\sqrt{3})$, $(\sqrt{3}, \infty)$ and CD on $(-\sqrt{3}, -1)$,

$(-1, 1)$, $(1, \sqrt{3})$. IPs at $(\pm\sqrt{3}, \sqrt[3]{4})$

31. $y = f(x) = 3 \sin x - \sin^3 x$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$; x -intercepts: $f(x) = 0 \Rightarrow$

$\sin x (3 - \sin^2 x) = 0 \Rightarrow \sin x = 0$ [since $\sin^2 x \leq 1 < 3$] $\Rightarrow x = n\pi$, n an integer.

C. $f(-x) = -f(x)$, so f is odd; the graph (shown for $-2\pi \leq x \leq 2\pi$) is symmetric about the origin and periodic with period 2π . D. No asymptote E. $f'(x) = 3 \cos x - 3 \sin^2 x \cos x = 3 \cos x (1 - \sin^2 x) = 3 \cos^3 x$.

$f'(x) > 0 \Leftrightarrow \cos x > 0 \Leftrightarrow x \in (2n\pi - \frac{\pi}{2}, 2n\pi + \frac{\pi}{2})$ for each integer n , and $f'(x) < 0 \Leftrightarrow$

$\cos x < 0 \Leftrightarrow x \in (2n\pi + \frac{\pi}{2}, 2n\pi + \frac{3\pi}{2})$ for each integer n . Thus, f is increasing on $(2n\pi - \frac{\pi}{2}, 2n\pi + \frac{\pi}{2})$

for each integer n , and f is decreasing on $(2n\pi + \frac{\pi}{2}, 2n\pi + \frac{3\pi}{2})$ for each integer n .

F. f has local maximum values $f(2n\pi + \frac{\pi}{2}) = 2$ and local minimum values $f(2n\pi + \frac{3\pi}{2}) = -2$.

G. $f''(x) = -9 \sin x \cos^2 x = -9 \sin x (1 - \sin^2 x) = -9 \sin x (1 - \sin x)(1 + \sin x)$. $f''(x) < 0 \Leftrightarrow$

$\sin x > 0$ and $\sin x \neq \pm 1 \Leftrightarrow x \in (2n\pi, 2n\pi + \frac{\pi}{2}) \cup (2n\pi + \frac{\pi}{2}, 2n\pi + \pi)$ for some integer n .

$f''(x) > 0 \Leftrightarrow \sin x < 0$ and $\sin x \neq \pm 1 \Leftrightarrow x \in ((2n-1)\pi, (2n-1)\pi + \frac{\pi}{2}) \cup ((2n-1)\pi + \frac{\pi}{2}, 2n\pi)$

for some integer n . Thus, f is CD on the intervals $(2n\pi, (2n + \frac{1}{2})\pi)$ and

$((2n + \frac{1}{2})\pi, (2n + 1)\pi)$ [hence CD on the intervals $(2n\pi, (2n + 1)\pi)$]

for each integer n , and f is CU on the intervals $((2n-1)\pi, (2n - \frac{1}{2})\pi)$

and $((2n - \frac{1}{2})\pi, 2n\pi)$ [hence CU on the intervals $((2n-1)\pi, 2n\pi)$] for

each integer n . f has inflection points at $(n\pi, 0)$ for each integer n .

H.

32. $y = f(x) = \sin x - \tan x$ A. $D = \{x \mid x \neq (2n + 1)\frac{\pi}{2}\}$ B. $y = 0 \Leftrightarrow \sin x = \tan x = \frac{\sin x}{\cos x} \Leftrightarrow$

$\sin x = 0$ or $\cos x = 1 \Leftrightarrow x = n\pi$ (x -intercepts), y -intercept $= f(0) = 0$ C. $f(-x) = -f(x)$, so the curve is symmetric about $(0, 0)$. Also periodic with period 2π D. $\lim_{x \rightarrow (\pi/2)^-} (\sin x - \tan x) = -\infty$ and

$\lim_{x \rightarrow (\pi/2)^+} (\sin x - \tan x) = \infty$, so $x = n\pi + \frac{\pi}{2}$ are VA.

E. $f'(x) = \cos x - \sec^2 x \leq 0$, so f decreases on each interval in its domain, that is, on $((2n-1)\frac{\pi}{2}, (2n+1)\frac{\pi}{2})$. F. No extreme values

G. $f''(x) = -\sin x - 2\sec^2 x \tan x = -\sin x (1 + 2\sec^3 x)$. Note that $1 + 2\sec^3 x \neq 0$ since $\sec^3 x \neq -\frac{1}{2}$. $f''(x) > 0$ for $-\frac{\pi}{2} < x < 0$ and $\frac{3\pi}{2} < x < 2\pi$, so f is CU on $((n - \frac{1}{2})\pi, n\pi)$ and CD on $(n\pi, (n + \frac{1}{2})\pi)$. f has IPs at $(n\pi, 0)$. Note also that $f'(0) = 0$, but $f'(\pi) = -2$.

H.

33. $y = f(x) = x \tan x, -\frac{\pi}{2} < x < \frac{\pi}{2}$ A. $D = (-\frac{\pi}{2}, \frac{\pi}{2})$ B. Intercepts are 0 C. $f(-x) = f(x)$, so the curve is symmetric about the y -axis. D. $\lim_{x \rightarrow (\pi/2)^-} x \tan x = \infty$ and $\lim_{x \rightarrow -(\pi/2)^+} x \tan x = \infty$, so $x = \frac{\pi}{2}$ and

$x = -\frac{\pi}{2}$ are VA. E. $f'(x) = \tan x + x \sec^2 x > 0 \Leftrightarrow 0 < x < \frac{\pi}{2}$, H.

so f increases on $(0, \frac{\pi}{2})$ and decreases on $(-\frac{\pi}{2}, 0)$.

F. Absolute and local minimum value $f(0) = 0$.

G. $y'' = 2\sec^2 x + 2x \tan x \sec^2 x > 0$ for $-\frac{\pi}{2} < x < \frac{\pi}{2}$, so f is CU on $(-\frac{\pi}{2}, \frac{\pi}{2})$. No IP

34. $y = f(x) = 2x - \tan x, -\frac{\pi}{2} < x < \frac{\pi}{2}$ A. $D = (-\frac{\pi}{2}, \frac{\pi}{2})$ B. y -intercept: $f(0) = 0$; x -intercepts: $f(0) = 0$

$\Leftrightarrow 2x = \tan x \Leftrightarrow x = 0$ or $x \approx \pm 1.17$ C. $f(-x) = -f(x)$, so f is odd; the graph is symmetric about the

origin. D. $\lim_{x \rightarrow (-\pi/2)^+} (2x - \tan x) = \infty$ and $\lim_{x \rightarrow (\pi/2)^-} (2x - \tan x) = -\infty$, so $x = \pm \frac{\pi}{2}$ are VA. No HA.

E. $f'(x) = 2 - \sec^2 x < 0 \Leftrightarrow |\sec x| > \sqrt{2}$ and $f'(x) > 0 \Leftrightarrow |\sec x| < \sqrt{2}$, so f is decreasing on $(-\frac{\pi}{2}, -\frac{\pi}{4})$, increasing on $(-\frac{\pi}{4}, \frac{\pi}{4})$, and decreasing again on $(\frac{\pi}{4}, \frac{\pi}{2})$ **F.** Local maximum

value $f(\frac{\pi}{4}) = \frac{\pi}{2} - 1$, local minimum value $f(-\frac{\pi}{4}) = -\frac{\pi}{2} + 1$

G. $f''(x) = -2 \sec x \cdot \sec x \tan x = -2 \tan x \sec^2 x$
 $= -2 \tan x (\tan^2 x + 1)$

so $f''(x) > 0 \Leftrightarrow \tan x < 0 \Leftrightarrow -\frac{\pi}{2} < x < 0$, and $f''(x) < 0 \Leftrightarrow$

$\tan x > 0 \Leftrightarrow 0 < x < \frac{\pi}{2}$. Thus, f is CU on $(-\frac{\pi}{2}, 0)$ and CD

on $(0, \frac{\pi}{2})$. f has an IP at $(0, 0)$.

35. $y = f(x) = \frac{1}{2}x - \sin x$, $0 < x < 3\pi$ **A.** $D = (0, 3\pi)$ **B.** No y -intercept. The x -intercept, approximately 1.9, can be found using Newton's Method. **C.** No symmetry **D.** No asymptote **E.** $f'(x) = \frac{1}{2} - \cos x > 0 \Leftrightarrow$

$\cos x < \frac{1}{2} \Leftrightarrow \frac{\pi}{3} < x < \frac{5\pi}{3}$ or $\frac{7\pi}{3} < x < 3\pi$, so f is increasing on $(\frac{\pi}{3}, \frac{5\pi}{3})$ and $(\frac{7\pi}{3}, 3\pi)$ and decreasing

on $(0, \frac{\pi}{3})$ and $(\frac{5\pi}{3}, \frac{7\pi}{3})$. **F.** Local minimum value $f(\frac{\pi}{3}) = \frac{\pi}{6} - \frac{\sqrt{3}}{2}$,

local maximum value $f(\frac{5\pi}{3}) = \frac{5\pi}{6} + \frac{\sqrt{3}}{2}$, local minimum value

$f(\frac{7\pi}{3}) = \frac{7\pi}{6} - \frac{\sqrt{3}}{2}$ **G.** $f''(x) = \sin x > 0 \Leftrightarrow 0 < x < \pi$ or

$2\pi < x < 3\pi$, so f is CU on $(0, \pi)$ and $(2\pi, 3\pi)$ and CD on $(\pi, 2\pi)$.

IPs at $(\pi, \frac{\pi}{2})$ and $(2\pi, \pi)$.

36. $y = f(x) = \cos^2 x - 2 \sin x$ **A.** $D = \mathbb{R}$ **B.** y -intercept: $f(0) = 1$ **C.** No symmetry, but f has period 2π .

D. No asymptote **E.** $y' = 2 \cos x (-\sin x) - 2 \cos x = -2 \cos x (\sin x + 1)$. $y' = 0 \Leftrightarrow \cos x = 0$ or $\sin x = -1 \Leftrightarrow x = (2n+1)\frac{\pi}{2}$. $y' > 0$ when $\cos x < 0$ since $\sin x + 1 \geq 0$ for all x . So $y' > 0$ and f is increasing on $((4n+1)\frac{\pi}{2}, (4n+3)\frac{\pi}{2})$; $y' < 0$ and f is decreasing on $((4n-1)\frac{\pi}{2}, (4n+1)\frac{\pi}{2})$. **F.** Local

maximum values $f((4n+3)\frac{\pi}{2}) = 2$, local minimum values $f((4n+1)\frac{\pi}{2}) = -2$

G. $y' = -2 \cos x (\sin x + 1) = -\sin 2x - 2 \cos x \Rightarrow$

$y'' = -2 \cos 2x + 2 \sin x = -2(1 - 2 \sin^2 x) + 2 \sin x$

$= 4 \sin^2 x + 2 \sin x - 2 = 2(2 \sin x - 1)(\sin x + 1)$

$y'' = 0 \Leftrightarrow \sin x = \frac{1}{2}$ or $-1 \Rightarrow x = \frac{\pi}{6} + 2n\pi, \frac{5\pi}{6} + 2n\pi$, or

$\frac{3\pi}{2} + 2n\pi$. $y'' > 0$ and f is CU on $(\frac{\pi}{6} + 2n\pi, \frac{5\pi}{6} + 2n\pi)$;

$y'' \leq 0$ and f is CD on $(\frac{5\pi}{6} + 2n\pi, \frac{\pi}{6} + 2(n+1)\pi)$.

IPs at $(\frac{\pi}{6} + 2n\pi, -\frac{1}{4})$ and $(\frac{5\pi}{6} + 2n\pi, -\frac{1}{4})$.

37. $y = f(x) = \sin 2x - 2 \sin x$ A. $D = \mathbb{R}$ B. y -intercept $= f(0) = 0$. $y = 0 \Leftrightarrow$

$$2 \sin x = \sin 2x = 2 \sin x \cos x \Leftrightarrow \sin x = 0 \text{ or } \cos x = 1 \Leftrightarrow x = n\pi \text{ (x-intercepts)}$$

C. $f(-x) = -f(x)$, so the curve is symmetric about $(0, 0)$.

Note: f is periodic with period 2π , so we determine E–G for $-\pi \leq x \leq \pi$. D. No asymptotes

$$\begin{aligned} \text{E. } f'(x) &= 2 \cos 2x - 2 \cos x = 2(2 \cos^2 x - 1 - \cos x) = 2(2 \cos x + 1)(\cos x - 1) > 0 \Leftrightarrow \cos x < -\frac{1}{2} \\ &\Leftrightarrow -\pi < x < -\frac{2\pi}{3} \text{ or } \frac{2\pi}{3} < x < \pi, \text{ so } f \text{ is increasing on } (-\pi, -\frac{2\pi}{3}), (\frac{2\pi}{3}, \pi) \text{ and decreasing on } (-\frac{2\pi}{3}, \frac{2\pi}{3}). \end{aligned}$$

$$\text{F. Local maximum value } f(-\frac{2\pi}{3}) = \frac{3\sqrt{3}}{2},$$

$$\text{local minimum value } f(\frac{2\pi}{3}) = -\frac{3\sqrt{3}}{2}$$

G. $f''(x) = -4 \sin 2x + 2 \sin x = 2 \sin x (1 - 4 \cos x) = 0$ when $x = 0, \pm\pi$ or $\cos x = \frac{1}{4}$. If $\alpha = \cos^{-1} \frac{1}{4}$, then f is CU on $(-\alpha, 0)$ and (α, π) and CD on $(-\pi, -\alpha)$ and $(0, \alpha)$.

IPs at $(0, 0), (\pm\pi, 0), (\alpha, -\frac{3\sqrt{15}}{8}), (-\alpha, \frac{3\sqrt{15}}{8})$.

38. $f(x) = \sin x - x$ A. $D = \mathbb{R}$ B. x -intercept $= 0 = y$ -intercept

C. $f(-x) = \sin(-x) - (-x) = -(\sin x - x) = -f(x)$, so f is odd.

D. No asymptote E. $f'(x) = \cos x - 1 \leq 0$ for all x , so f is decreasing on $(-\infty, \infty)$. F. No extreme values G. $f''(x) = -\sin x \Rightarrow$

$f''(x) > 0 \Leftrightarrow \sin x < 0 \Leftrightarrow (2n-1)\pi < x < 2n\pi$, so f is CU on $((2n-1)\pi, 2n\pi)$ and CD on $(2n\pi, (2n+1)\pi)$, n an integer. Points of inflection occur when $x = n\pi$.

$$39. y = f(x) = \frac{\sin x}{1 + \cos x} \left[\begin{array}{l} \text{when} \\ \cos x \neq -1 \end{array} \frac{\sin x}{1 + \cos x} \cdot \frac{1 - \cos x}{1 - \cos x} = \frac{\sin x (1 - \cos x)}{\sin^2 x} = \frac{1 - \cos x}{\sin x} = \csc x - \cot x \right]$$

A. The domain of f is the set of all real numbers except odd integer multiples of π . B. y -intercept: $f(0) = 0$; x -intercepts: $x = n\pi$, n an even integer. C. $f(-x) = -f(x)$, so f is an odd function; the graph is symmetric about the origin and has period 2π .

D. When n is an odd integer, $\lim_{x \rightarrow (n\pi)^-} f(x) = \infty$ and $\lim_{x \rightarrow (n\pi)^+} f(x) = -\infty$, so $x = n\pi$ is a VA for each odd integer n . No HA.

$$\text{E. } f'(x) = \frac{(1 + \cos x) \cdot \cos x - \sin x(-\sin x)}{(1 + \cos x)^2} = \frac{1 + \cos x}{(1 + \cos x)^2} = \frac{1}{1 + \cos x}. f'(x) > 0 \text{ for all } x \text{ except odd}$$

multiples of π , so f is increasing on $((2k-1)\pi, (2k+1)\pi)$ for each integer k . F. No extreme values

$$G. f''(x) = \frac{\sin x}{(1 + \cos x)^2} > 0 \Rightarrow \sin x > 0 \Rightarrow$$

$x \in (2k\pi, (2k+1)\pi)$ and $f''(x) < 0$ on $((2k-1)\pi, 2k\pi)$

for each integer k . f is CU on $(2k\pi, (2k+1)\pi)$ and CD on

$((2k-1)\pi, 2k\pi)$ for each integer k . f has IPs at $(2k\pi, 0)$

for each integer k .

40. $y = f(x) = \cos x / (2 + \sin x)$ A. $D = \mathbb{R}$ Note: f is periodic with period 2π , so we determine B–G on $[0, 2\pi]$.

B. x -intercepts $\frac{\pi}{2}, \frac{3\pi}{2}$, y -intercept $= f(0) = \frac{1}{2}$ C. No symmetry other than periodicity D. No asymptote

$$E. f'(x) = \frac{(2 + \sin x)(-\sin x) - \cos x (\cos x)}{(2 + \sin x)^2} = -\frac{2 \sin x + 1}{(2 + \sin x)^2}. f'(x) > 0 \Leftrightarrow 2 \sin x + 1 < 0 \Leftrightarrow$$

$\sin x < -\frac{1}{2} \Leftrightarrow \frac{7\pi}{6} < x < \frac{11\pi}{6}$, so f is increasing on $(\frac{7\pi}{6}, \frac{11\pi}{6})$ and decreasing on $(0, \frac{7\pi}{6})$, $(\frac{11\pi}{6}, 2\pi)$.

F. Local minimum value $f(\frac{7\pi}{6}) = -\frac{1}{\sqrt{3}}$, local maximum value $f(\frac{11\pi}{6}) = \frac{1}{\sqrt{3}}$

$$G. f''(x) = -\frac{(2 + \sin x)^2 (2 \cos x) - (2 \sin x + 1) 2(2 + \sin x) \cos x}{(2 + \sin x)^4} = -\frac{2 \cos x (1 - \sin x)}{(2 + \sin x)^3} > 0 \Leftrightarrow$$

$\cos x < 0 \Leftrightarrow \frac{\pi}{2} < x < \frac{3\pi}{2}$, so f is CU on $(\frac{\pi}{2}, \frac{3\pi}{2})$ and CD on $(0, \frac{\pi}{2})$ and $(\frac{3\pi}{2}, 2\pi)$. IP at $(\frac{\pi}{2}, 0)$, $(\frac{3\pi}{2}, 0)$

$$41. y = -\frac{W}{24EI}x^4 + \frac{WL}{12EI}x^3 - \frac{WL^2}{24EI}x^2 = -\frac{W}{24EI}x^2(x^2 - 2Lx + L^2) \\ = -\frac{W}{24EI}x^2(x - L)^2 = cx^2(x - L)^2$$

where $c = -\frac{W}{24EI}$ is a negative constant and $0 \leq x \leq L$. We sketch

$f(x) = cx^2(x - L)^2$ for $c = -1$. $f(0) = f(L) = 0$.

$f'(x) = cx^2[2(x - L)] + (x - L)^2(2cx) = 2cx(x - L)[x + (x - L)] = 2cx(x - L)(2x - L)$. So for

$0 < x < L$, $f'(x) > 0 \Leftrightarrow x(x - L)(2x - L) < 0$ (since $c < 0$) $\Leftrightarrow L/2 < x < L$ and $f'(x) < 0 \Leftrightarrow$

$0 < x < L/2$. So f is increasing on $(L/2, L)$ and decreasing on $(0, L/2)$, and there is a local and absolute minimum at $(L/2, f(L/2)) = (L/2, cL^4/16)$.

$$f'(x) = 2c[x(x - L)(2x - L)] \Rightarrow$$

$$f''(x) = 2c[1(x - L)(2x - L) + x(1)(2x - L) + x(x - L)(2)] = 2c(6x^2 - 6Lx + L^2) = 0 \Leftrightarrow$$

$$x = \frac{6L \pm \sqrt{12L^2}}{12} = \frac{1}{2}L \pm \frac{\sqrt{3}}{6}L, \text{ and these are the } x\text{-coordinates of the two inflection points.}$$

42. $F(x) = -\frac{k}{x^2} + \frac{k}{(x-2)^2}$, where $k > 0$ and $0 < x < 2$. For $0 < x < 2$,

$$x - 2 < 0, \text{ so } F'(x) = \frac{2k}{x^3} - \frac{2k}{(x-2)^3} > 0 \text{ and } F \text{ is increasing.}$$

$$\lim_{x \rightarrow 0^+} F(x) = -\infty \text{ and } \lim_{x \rightarrow 2^-} F(x) = \infty, \text{ so } x = 0 \text{ and } x = 2 \text{ are vertical}$$

asymptotes. Notice that when the middle particle is at $x = 1$, the net force acting on it is 0. When $x > 1$, the net force is positive, meaning that it acts to the right. And if the particle approaches $x = 2$, the force on it rapidly becomes very large. When $x < 1$, the net force is negative, so it acts to the left. If the particle approaches 0, the force becomes very large to the left.

43. $y = \frac{x^2 + 1}{x + 1}$. Long division gives us:

$$\begin{array}{r} x-1 \\ x+1 \overline{) x^2 + 1} \\ \underline{x^2 + x} \\ -x + 1 \\ \underline{-x - 1} \\ 2 \end{array}$$

$$\text{Thus, } y = f(x) = \frac{x^2 + 1}{x + 1} = x - 1 + \frac{2}{x + 1} \text{ and } f(x) - (x - 1) = \frac{2}{x + 1} = \frac{\frac{2}{x}}{1 + \frac{1}{x}} \quad [\text{for } x \neq 0] \rightarrow 0$$

as $x \rightarrow \pm\infty$. So the line $y = x - 1$ is a slant asymptote (SA).

44. $y = \frac{2x^3 + x^2 + x + 3}{x^2 + 2x}$. Long division gives us:

$$\begin{array}{r} 2x-3 \\ x^2+2x \overline{) 2x^3 + x^2 + x + 3} \\ \underline{2x^3 + 4x^2} \\ -3x^2 + x \\ \underline{-3x^2 - 6x} \\ 7x + 3 \end{array}$$

$$\text{Thus, } y = f(x) = \frac{2x^3 + x^2 + x + 3}{x^2 + 2x} = 2x - 3 + \frac{7x + 3}{x^2 + 2x} \text{ and } f(x) - (2x - 3) = \frac{7x + 3}{x^2 + 2x} = \frac{\frac{7}{x} + \frac{3}{x^2}}{1 + \frac{2}{x}}$$

[for $x \neq 0$] $\rightarrow 0$ as $x \rightarrow \pm\infty$. So the line $y = 2x - 3$ is a SA.

45. $y = \frac{4x^3 - 2x^2 + 5}{2x^2 + x - 3}$. Long division gives us:

$$\begin{array}{r} 2x - 2 \\ 2x^2 + x - 3 \overline{) 4x^3 - 2x^2 + 5} \\ \underline{4x^3 + 2x^2 - 6x} \\ -4x^2 + 6x + 5 \\ \underline{-4x^2 - 2x + 6} \\ 8x - 1 \end{array}$$

Thus, $y = f(x) = \frac{4x^3 - 2x^2 + 5}{2x^2 + x - 3} = 2x - 2 + \frac{8x - 1}{2x^2 + x - 3}$ and

$$f(x) - (2x - 2) = \frac{8x - 1}{2x^2 + x - 3} = \frac{\frac{8}{x} - \frac{1}{x^2}}{2 + \frac{1}{x} - \frac{3}{x^2}} \quad [\text{for } x \neq 0] \rightarrow 0 \text{ as } x \rightarrow \pm\infty. \text{ So the line } y = 2x - 2 \text{ is}$$

a SA.

46. $y = \frac{5x^4 + x^2 + x}{x^3 - x^2 + 2}$. Long division gives us:

$$\begin{array}{r} 5x + 5 \\ x^3 - x^2 + 2 \overline{) 5x^4 + x^2 + x} \\ \underline{5x^4 - 5x^3 + 10x} \\ 5x^3 + x^2 - 9x \\ \underline{5x^3 - 5x^2 + 10} \\ 6x^2 - 9x - 10 \end{array}$$

Thus, $y = f(x) = \frac{5x^4 + x^2 + x}{x^3 - x^2 + 2} = 5x + 5 + \frac{6x^2 - 9x - 10}{x^3 - x^2 + 2}$ and

$$f(x) - (5x + 5) = \frac{6x^2 - 9x - 10}{x^3 - x^2 + 2} = \frac{\frac{6}{x} - \frac{9}{x^2} - \frac{10}{x^3}}{1 - \frac{1}{x} + \frac{2}{x^3}} \quad [\text{for } x \neq 0] \rightarrow 0 \text{ as } x \rightarrow \pm\infty. \text{ So the line } y = 5x + 5$$

is a SA.

47. $y = f(x) = \frac{-2x^2 + 5x - 1}{2x - 1} = -x + 2 + \frac{1}{2x - 1}$ A. $D = \{x \in \mathbb{R} \mid x \neq \frac{1}{2}\} = (-\infty, \frac{1}{2}) \cup (\frac{1}{2}, \infty)$

B. y -intercept: $f(0) = 1$; x -intercepts: $f(x) = 0 \Rightarrow -2x^2 + 5x - 1 = 0 \Rightarrow x = \frac{-5 \pm \sqrt{17}}{-4} \Rightarrow$

$x \approx 0.22, 2.28$. C. No symmetry

D. $\lim_{x \rightarrow (1/2)^-} f(x) = -\infty$ and $\lim_{x \rightarrow (1/2)^+} f(x) = \infty$, so $x = \frac{1}{2}$ is a VA.

$\lim_{x \rightarrow \pm\infty} [f(x) - (-x + 2)] = \lim_{x \rightarrow \pm\infty} \frac{1}{2x - 1} = 0$, so the line $y = -x + 2$ is a SA.

E. $f'(x) = -1 - \frac{2}{(2x-1)^2} < 0$ for $x \neq \frac{1}{2}$, so f is decreasing

on $(-\infty, \frac{1}{2})$ and $(\frac{1}{2}, \infty)$. F. No extreme values

G. $f'(x) = -1 - 2(2x-1)^{-2} \Rightarrow$

$f''(x) = -2(-2)(2x-1)^{-3}(2) = \frac{8}{(2x-1)^3}$, so $f''(x) > 0$ when

$x > \frac{1}{2}$ and $f''(x) < 0$ when $x < \frac{1}{2}$. Thus, f is CU on $(\frac{1}{2}, \infty)$ and CD

on $(-\infty, \frac{1}{2})$. No IP

48. $y = f(x) = \frac{x^2 + 12}{x - 2} = x + 2 + \frac{16}{x - 2}$ A. $D = \{x \in \mathbb{R} \mid x \neq 2\} = (-\infty, 2) \cup (2, \infty)$

B. y -intercept: $f(0) = -6$; no x -intercepts. C. No symmetry D. $\lim_{x \rightarrow 2^-} f(x) = -\infty$ and $\lim_{x \rightarrow 2^+} f(x) = \infty$,

so $x = 2$ is a VA. $\lim_{x \rightarrow \pm\infty} [f(x) - (x + 2)] = \lim_{x \rightarrow \pm\infty} \frac{16}{x - 2} = 0$, so the line $y = x + 2$ is a slant asymptote.

E. $f'(x) = 1 - \frac{16}{(x-2)^2} = \frac{x^2 - 4x - 12}{(x-2)^2} = \frac{(x-6)(x+2)}{(x-2)^2}$, so $f'(x) > 0$ when $x < -2$ or $x > 6$ and

$f'(x) < 0$ when $-2 < x < 2$ or $2 < x < 6$. Thus, f is increasing on $(-\infty, -2)$ and $(6, \infty)$ and decreasing on $(-2, 2)$ and $(2, 6)$.

F. Local maximum value $f(-2) = -4$,

local minimum value $f(6) = 12$

G. $f''(x) = 16(-2)(x-2)^{-3} = \frac{32}{(x-2)^3}$, so $f''(x) > 0$ for

$x > 2$ and $f''(x) < 0$ for $x < 2$. f is CU on $(2, \infty)$ and CD

on $(-\infty, 2)$. No IP

49. $y = f(x) = (x^2 + 4)/x = x + 4/x$ A. $D = \{x \mid x \neq 0\} = (-\infty, 0) \cup (0, \infty)$ B. No intercept

C. $f(-x) = -f(x) \Rightarrow$ symmetry about the origin D. $\lim_{x \rightarrow \infty} (x + 4/x) = \infty$ but $f(x) - x = 4/x \rightarrow 0$ as

$x \rightarrow \pm\infty$, so $y = x$ is a slant asymptote. $\lim_{x \rightarrow 0^+} (x + 4/x) = \infty$ and

$\lim_{x \rightarrow 0^-} (x + 4/x) = -\infty$, so $x = 0$ is a VA. E. $f'(x) = 1 - 4/x^2 > 0$

$\Leftrightarrow x^2 > 4 \Leftrightarrow x > 2$ or $x < -2$, so f is increasing on $(-\infty, -2)$

and $(2, \infty)$ and decreasing on $(-2, 0)$ and $(0, 2)$.

F. Local maximum value $f(-2) = -4$, local minimum value $f(2) = 4$

G. $f''(x) = 8/x^3 > 0 \Leftrightarrow x > 0$ so f is CU on $(0, \infty)$ and CD

on $(-\infty, 0)$. No IP

50. $y = f(x) = \frac{x^2 + x + 1}{x} = x + 1 + \frac{1}{x}$ A. $D = \{x \mid x \neq 0\} = (-\infty, 0) \cup (0, \infty)$ B. No intercept

(x -intercepts would occur when $x^2 + x + 1 = 0$ but this equation has no real roots since $b^2 - 4ac = -3 < 0$.)

C. No symmetry D. $\lim_{x \rightarrow \infty} (x + 1 + 1/x) = \pm\infty$, so no HA. But $(x + 1 + 1/x) - (x + 1) = 1/x \rightarrow 0$ as

$x \rightarrow \pm\infty$, so $y = x + 1$ is a slant asymptote. Also $\lim_{x \rightarrow 0^+} (x + 1 + 1/x) = \infty$, $\lim_{x \rightarrow 0^-} (x + 1 + 1/x) = -\infty$, so

$x = 0$ is a VA. E. $f'(x) = 1 - 1/x^2 > 0$ when $x^2 > 1 \Leftrightarrow x > 1$ or

$x < -1$; $f'(x) < 0 \Leftrightarrow -1 < x < 1$. So f is increasing on $(-\infty, -1)$,

$(1, \infty)$ and decreasing on $(-1, 0)$, $(0, 1)$. F. $f(1) = 3$ is a local

minimum, $f(-1) = -1$ is a local maximum. G. $f''(x) = 2/x^3 > 0$

$\Leftrightarrow x > 0$, so f is CU on $(0, \infty)$ and CD on $(-\infty, 0)$. No IP

51. $y = f(x) = \frac{2x^3 + x^2 + 1}{x^2 + 1} = 2x + 1 + \frac{-2x}{x^2 + 1}$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 1$; x -intercept: $f(x) = 0$

$\Rightarrow 0 = 2x^3 + x^2 + 1 = (x + 1)(2x^2 - x + 1) \Rightarrow x = -1$ C. No symmetry D. No VA

$\lim_{x \rightarrow \pm\infty} [f(x) - (2x + 1)] = \lim_{x \rightarrow \pm\infty} \frac{-2x}{x^2 + 1} = \lim_{x \rightarrow \pm\infty} \frac{-2/x}{1 + 1/x^2} = 0$, so the line $y = 2x + 1$ is a slant asymptote.

$$\begin{aligned} \text{E. } f'(x) &= 2 + \frac{(x^2 + 1)(-2) - (-2x)(2x)}{(x^2 + 1)^2} = \frac{2(x^4 + 2x^2 + 1) - 2x^2 - 2 + 4x^2}{(x^2 + 1)^2} \\ &= \frac{2x^4 + 6x^2}{(x^2 + 1)^2} = \frac{2x^2(x^2 + 3)}{(x^2 + 1)^2} \end{aligned}$$

so $f'(x) > 0$ if $x \neq 0$. Thus, f is increasing on $(-\infty, 0)$ and $(0, \infty)$. Since f is continuous at 0, f is increasing on $\mathbb{R}$. F. No extreme values

$$\begin{aligned} \text{G. } f''(x) &= \frac{(x^2 + 1)^2 \cdot (8x^3 + 12x) - (2x^4 + 6x^2) \cdot 2(x^2 + 1)(2x)}{[(x^2 + 1)^2]^2} \quad \text{H.} \\ &= \frac{4x(x^2 + 1)[(x^2 + 1)(2x^2 + 3) - 2x^4 - 6x^2]}{(x^2 + 1)^4} \\ &= \frac{4x(-x^2 + 3)}{(x^2 + 1)^3} \end{aligned}$$

so $f''(x) > 0$ for $x < -\sqrt{3}$ and $0 < x < \sqrt{3}$, and $f''(x) < 0$ for

$-\sqrt{3} < x < 0$ and $x > \sqrt{3}$. f is CU on $(-\infty, -\sqrt{3})$ and $(0, \sqrt{3})$,

and CD on $(-\sqrt{3}, 0)$ and $(\sqrt{3}, \infty)$. There are three IPs: $(0, 1)$, $(-\sqrt{3}, -\frac{3}{2}\sqrt{3} + 1) \approx (-1.73, -1.60)$, and

$(\sqrt{3}, \frac{3}{2}\sqrt{3} + 1) \approx (1.73, 3.60)$.

52. $y = f(x) = \frac{(x + 1)^3}{(x - 1)^2} = \frac{x^3 + 3x^2 + 3x + 1}{x^2 - 2x + 1} = x + 5 + \frac{12x - 4}{(x - 1)^2}$

A. $D = \{x \in \mathbb{R} \mid x \neq 1\} = (-\infty, 1) \cup (1, \infty)$ B. y -intercept: $f(0) = 1$;

x -intercept: $f(x) = 0 \Rightarrow x = -1$ C. No symmetry D. $\lim_{x \rightarrow 1} f(x) = \infty$, so $x = 1$ is a VA.

$$\lim_{x \rightarrow \pm\infty} [f(x) - (x + 5)] = \lim_{x \rightarrow \pm\infty} \frac{12x - 4}{x^2 - 2x + 1} = \lim_{x \rightarrow \pm\infty} \frac{\frac{12}{x} - \frac{4}{x^2}}{1 - \frac{2}{x} + \frac{1}{x^2}} = 0, \text{ so the line } y = x + 5 \text{ is a SA.}$$

$$\begin{aligned} \text{E. } f'(x) &= \frac{(x-1)^2 \cdot 3(x+1)^2 - (x+1)^3 \cdot 2(x-1)}{[(x-1)^2]^2} \\ &= \frac{(x-1)(x+1)^2[3(x-1) - 2(x+1)]}{(x-1)^4} = \frac{(x+1)^2(x-5)}{(x-1)^3} \end{aligned}$$

so $f'(x) > 0$ when $x < -1$, $-1 < x < 1$, or $x > 5$, and $f'(x) < 0$ when $1 < x < 5$. f is increasing on $(-\infty, 1)$ and $(5, \infty)$ and decreasing on $(1, 5)$.

F. Local minimum value $f(5) = \frac{216}{16} = \frac{27}{2}$, no local maximum

$$\begin{aligned} \text{G. } f''(x) &= \frac{(x-1)^3[(x-1)^2 + (x-5) \cdot 2(x+1)] - (x+1)^2(x-5) \cdot 3(x-1)^2}{[(x-1)^3]^2} \\ &= \frac{(x-1)^2(x+1)\{(x-1)[(x+1) + 2(x-5)] - 3(x+1)(x-5)\}}{(x-1)^6} \\ &= \frac{(x+1)\{(x-1)[3x-9] - 3(x^2-4x-5)\}}{(x-1)^4} = \frac{(x+1)(24)}{(x-1)^4} \end{aligned}$$

so $f''(x) > 0$ if $-1 < x < 1$ or $x > 1$, and $f''(x) < 0$ if $x < -1$. Thus, f is CU on $(-1, 1)$ and $(1, \infty)$ and CD on $(-\infty, -1)$. IP at $(-1, 0)$

$$53. y = f(x) = \sqrt{4x^2 + 9} \Rightarrow f'(x) = \frac{4x}{\sqrt{4x^2 + 9}} \Rightarrow$$

$$f''(x) = \frac{\sqrt{4x^2 + 9} \cdot 4 - 4x \cdot 4x/\sqrt{4x^2 + 9}}{4x^2 + 9} = \frac{4(4x^2 + 9) - 16x^2}{(4x^2 + 9)^{3/2}} = \frac{36}{(4x^2 + 9)^{3/2}}. \text{ } f \text{ is defined on}$$

$(-\infty, \infty)$. $f(-x) = f(x)$, so f is even, which means its graph is symmetric about the y -axis. The y -intercept is $f(0) = 3$. There are no x -intercepts since $f(x) > 0$ for all x .

$$\begin{aligned} \lim_{x \rightarrow \infty} (\sqrt{4x^2 + 9} - 2x) &= \lim_{x \rightarrow \infty} \frac{(\sqrt{4x^2 + 9} - 2x)(\sqrt{4x^2 + 9} + 2x)}{\sqrt{4x^2 + 9} + 2x} \\ &= \lim_{x \rightarrow \infty} \frac{(4x^2 + 9) - 4x^2}{\sqrt{4x^2 + 9} + 2x} = \lim_{x \rightarrow \infty} \frac{9}{\sqrt{4x^2 + 9} + 2x} = 0 \end{aligned}$$

$$\text{and, similarly, } \lim_{x \rightarrow -\infty} (\sqrt{4x^2 + 9} + 2x) = \lim_{x \rightarrow -\infty} \frac{9}{\sqrt{4x^2 + 9} - 2x} = 0,$$

so $y = \pm 2x$ are slant asymptotes. f is decreasing on $(-\infty, 0)$ and increasing on $(0, \infty)$ with local minimum $f(0) = 3$. $f''(x) > 0$ for all x , so f is CU on $\mathbb{R}$.

$$54. y = f(x) = \sqrt{x^2 + 4x} = \sqrt{x(x+4)}. \quad x(x+4) \geq 0 \Leftrightarrow x \leq -4 \text{ or } x \geq 0, \text{ so } D = (-\infty, -4] \cup [0, \infty).$$

y -intercept: $f(0) = 0$; x -intercepts: $f(x) = 0 \Rightarrow x = -4, 0$.

$$\begin{aligned}\sqrt{x^2+4x} \mp (x+2) &= \frac{\sqrt{x^2+4x} \mp (x+2)}{1} \cdot \frac{\sqrt{x^2+4x} \pm (x+2)}{\sqrt{x^2+4x} \pm (x+2)} = \frac{(x^2+4x) - (x^2+4x+4)}{\sqrt{x^2+4x} \pm (x+2)} \\ &= \frac{-4}{\sqrt{x^2+4x} \pm (x+2)}\end{aligned}$$

so $\lim_{x \rightarrow \pm\infty} [f(x) \mp (x+2)] = 0$. Thus, the graph of f approaches the slant asymptote $y = x + 2$ as $x \rightarrow \infty$ and it

approaches the slant asymptote $y = -(x + 2)$ as $x \rightarrow -\infty$. $f'(x) = \frac{x+2}{\sqrt{x^2+4x}}$, so $f'(x) < 0$ for $x < -4$

and $f'(x) > 0$ for $x > 0$; that is, f is decreasing on $(-\infty, -4)$ and increasing on $(0, \infty)$. There are no local extreme values.

$$\begin{aligned} f'(x) &= (x+2)(x^2+4x)^{-1/2} \Rightarrow \\ f''(x) &= (x+2) \cdot \left(-\frac{1}{2}\right)(x^2+4x)^{-3/2} \cdot (2x+4) + (x^2+4x)^{-1/2} \\ &= (x^2+4x)^{-3/2} [-(x+2)^2 + (x^2+4x)] \\ &= -4(x^2+4x)^{-3/2} < 0 \text{ on } D \end{aligned}$$

so f is CD on $(-\infty, -4)$ and $(0, \infty)$. No IP

55. $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1 \Rightarrow y = \pm \frac{b}{a} \sqrt{x^2 - a^2}$. Now

$$\lim_{x \rightarrow \infty} \left[\frac{b}{a} \sqrt{x^2 - a^2} - \frac{b}{a} x \right] = \frac{b}{a} \cdot \lim_{x \rightarrow \infty} (\sqrt{x^2 - a^2} - x) \frac{\sqrt{x^2 - a^2} + x}{\sqrt{x^2 - a^2} + x} = \frac{b}{a} \cdot \lim_{x \rightarrow \infty} \frac{-a^2}{\sqrt{x^2 - a^2} + x} = 0,$$

which shows that $y = \frac{b}{a}x$ is a slant asymptote. Similarly,

$$\lim_{x \rightarrow \infty} \left[-\frac{b}{a} \sqrt{x^2 - a^2} - \left(-\frac{b}{a} x \right) \right] = -\frac{b}{a} \cdot \lim_{x \rightarrow \infty} \frac{-a^2}{\sqrt{x^2 - a^2} + x} = 0, \text{ so } y = -\frac{b}{a}x \text{ is a slant asymptote.}$$

56. $f(x) - x^2 = \frac{x^3 + 1}{x} - x^2 = \frac{x^3 + 1 - x^3}{x} = \frac{1}{x}$, and $\lim_{x \rightarrow \pm\infty} \frac{1}{x} = 0$. Therefore, $\lim_{x \rightarrow \pm\infty} [f(x) - x^2] = 0$, and so

the graph of f is asymptotic to that of $y = x^2$. For purposes of differentiation, we will use $f(x) = x^2 + 1/x$.

A. $D = \{x \mid x \neq 0\}$ **B.** No y -intercept; to find the x -intercept, we set $y = 0 \Leftrightarrow x = -1$.

C. No symmetry D. $\lim_{x \rightarrow 0^+} \frac{x^3 + 1}{x} = \infty$ and $\lim_{x \rightarrow 0^-} \frac{x^3 + 1}{x} = -\infty$,

so $x = 0$ is a vertical asymptote. Also, the graph is asymptotic to the

parabola $y = x^2$, as shown above. E. $f'(x) = 2x - 1/x^2 > 0 \Leftrightarrow$

$x > \frac{1}{\sqrt[3]{2}}$, so f is increasing on $(\frac{1}{\sqrt[3]{2}}, \infty)$ and decreasing on $(-\infty, 0)$ and

$\left(0, \frac{1}{\sqrt[3]{2}}\right)$. **F.** Local minimum value $f\left(\frac{1}{\sqrt[3]{2}}\right) = \frac{3\sqrt[3]{3}}{2}$, no local maximum

G. $f''(x) = 2 + 2/x^3 > 0 \Leftrightarrow x < -1$ or $x > 0$, so f is CU on $(-\infty, -1)$ and $(0, \infty)$, and CD on $(-1, 0)$. IP at $(-1, 0)$

57. $\lim_{x \rightarrow \pm\infty} [f(x) - x^3] = \lim_{x \rightarrow \pm\infty} \frac{x^4 + 1}{x} - \frac{x^4}{x} = \lim_{x \rightarrow \pm\infty} \frac{1}{x} = 0$, so the graph of f is asymptotic to that of $y = x^3$.

A. $D = \{x \mid x \neq 0\}$ B. No intercept C. f is symmetric about the origin. D. $\lim_{x \rightarrow 0^-} \left(x^3 + \frac{1}{x}\right) = -\infty$ and

$\lim_{x \rightarrow 0^+} \left(x^3 + \frac{1}{x}\right) = \infty$, so $x = 0$ is a vertical asymptote, and as shown above, the graph of f is asymptotic to

that of $y = x^3$. E. $f'(x) = 3x^2 - 1/x^2 > 0 \Leftrightarrow x^4 > \frac{1}{3} \Leftrightarrow$

$|x| > \frac{1}{\sqrt[4]{3}}$, so f is increasing on $(-\infty, -\frac{1}{\sqrt[4]{3}})$ and $(\frac{1}{\sqrt[4]{3}}, \infty)$ and

decreasing on $(-\frac{1}{\sqrt[4]{3}}, 0)$ and $(0, \frac{1}{\sqrt[4]{3}})$. F. Local maximum value

$f(-\frac{1}{\sqrt[4]{3}}) = -4 \cdot 3^{-5/4}$, local minimum value $f(\frac{1}{\sqrt[4]{3}}) = 4 \cdot 3^{-5/4}$

G. $f''(x) = 6x + 2/x^3 > 0 \Leftrightarrow x > 0$, so f is CU on $(0, \infty)$ and

CD on $(-\infty, 0)$. No IP

H.

58. $\lim_{x \rightarrow \pm\infty} [f(x) - \cos x] = \lim_{x \rightarrow \pm\infty} 1/x^2 = 0$, so the graph of f is

asymptotic to that of $\cos x$. The intercepts can only be found

approximately. $f(x) = f(-x)$, so f is even. $\lim_{x \rightarrow 0} \left(\cos x + \frac{1}{x^2}\right) = \infty$, so

$x = 0$ is a vertical asymptote. We don't need to calculate the derivatives,

since we know the asymptotic behavior of the curve.

4.6 Graphing with Calculus and Calculators

$$1. f(x) = 4x^4 - 32x^3 + 89x^2 - 95x + 29 \Rightarrow f'(x) = 16x^3 - 96x^2 + 178x - 95 \Rightarrow$$

$$f''(x) = 48x^2 - 192x + 178. f(x) = 0 \Leftrightarrow x \approx 0.5, 1.60; f'(x) = 0 \Leftrightarrow x \approx 0.92, 2.5, 2.58 \text{ and}$$

$$f''(x) = 0 \Leftrightarrow x \approx 1.46, 2.54.$$

From the graphs of f' , we estimate that $f' < 0$ and that f is decreasing on $(-\infty, 0.92)$ and $(2.5, 2.58)$, and that

$f' > 0$ and f is increasing on $(0.92, 2.5)$ and $(2.58, \infty)$ with local minimum values $f(0.92) \approx -5.12$ and

$f(2.58) \approx 3.998$ and local maximum value $f(2.5) = 4$. The graphs of f' make it clear that f has a maximum and a minimum near $x = 2.5$, shown more clearly in the fourth graph.

From the graph of f'' , we estimate that $f'' > 0$ and that f is CU on $(-\infty, 1.46)$ and $(2.54, \infty)$, and that $f'' < 0$ and f is CD on $(1.46, 2.54)$. There are inflection points at about $(1.46, -1.40)$ and $(2.54, 3.999)$.

$$2. f(x) = x^6 - 15x^5 + 75x^4 - 125x^3 - x \Rightarrow$$

$$f'(x) = 6x^5 - 75x^4 + 300x^3 - 375x^2 - 1 \Rightarrow f''(x) = 30x^4 - 300x^3 + 900x^2 - 750x.$$

$$f(x) = 0 \Leftrightarrow x = 0 \text{ or } x \approx 5.33; f'(x) = 0 \Leftrightarrow x \approx 2.50, 4.95, \text{ or } 5.05;$$

$$f''(x) = 0 \Leftrightarrow x = 0, 5 \text{ or } x \approx 1.38, 3.62.$$

From the graphs of f' , we estimate that f is decreasing on $(-\infty, 2.50)$, increasing on $(2.50, 4.95)$, decreasing on $(4.95, 5.05)$, and increasing on $(5.05, \infty)$, with local minimum values $f(2.50) \approx -246.6$ and $f(5.05) \approx -5.03$, and local maximum value $f(4.95) \approx -4.965$ (notice the second graph of f). From the graph of f'' , we estimate that f is CU on $(-\infty, 0)$, CD on $(0, 1.38)$, CU on $(1.38, 3.62)$, CD on $(3.62, 5)$, and CU on $(5, \infty)$. There are inflection points at $(0, 0)$ and $(5, -5)$, and at about $(1.38, -126.38)$ and $(3.62, -128.62)$.

$$3. f(x) = \sqrt[3]{x^2 - 3x - 5} \Rightarrow f'(x) = \frac{1}{3} \frac{2x - 3}{(x^2 - 3x - 5)^{2/3}} \Rightarrow f''(x) = -\frac{2}{9} \frac{x^2 - 3x + 24}{(x^2 - 3x - 5)^{5/3}}$$

Note: With some CAS's, including Maple, it is necessary to define $f(x) = \frac{x^2 - 3x - 5}{|x^2 - 3x - 5|^{1/3}}$,

since the CAS does not compute real cube roots of negative numbers. We estimate from the graph of f' that f is

increasing on $(1.5, \infty)$, and decreasing on $(-\infty, 1.5)$. f has no maximum. Minimum value: $f(1.5) \approx -1.9$. From the graph of f'' , we estimate that f is CU on $(-1.2, 4.2)$ and CD on $(-\infty, -1.2)$ and $(4.2, \infty)$. IP at $(-1.2, 0)$ and $(4.2, 0)$.

$$4. f(x) = \frac{x^4 + x^3 - 2x^2 + 2}{x^2 + x - 2} \Rightarrow f'(x) = 2 \frac{x^5 + 2x^4 - 3x^3 - 4x^2 + 2x - 1}{(x^2 + x - 2)^2} \Rightarrow$$

$$f''(x) = 2 \frac{x^6 + 3x^5 - 3x^4 - 11x^3 + 12x^2 + 18x - 2}{(x^2 + x - 2)^3}$$

We estimate from the graph of f' that f is increasing on $(-2.4, -2)$, $(-2, -1.5)$ and $(1.5, \infty)$ and decreasing on $(-\infty, -2.4)$, $(-1.5, 1)$ and $(1, 1.5)$. Local maximum value: $f(-1.5) \approx 0.7$.

Local minimum values: $f(-2.4) \approx 7.2$, $f(1.5) \approx 3.4$. From the graph of f'' , we estimate that f is CU on $(-\infty, -2)$, $(-1.1, 0.1)$ and $(1, \infty)$ and CD on $(-2, -1.1)$ and $(0.1, 1)$. f has IP at $(-1.1, 0.2)$ and $(0.1, -1.1)$.

$$5. f(x) = \frac{x}{x^3 - x^2 - 4x + 1} \Rightarrow f'(x) = \frac{-2x^3 + x^2 + 1}{(x^3 - x^2 - 4x + 1)^2} \Rightarrow$$

$$f''(x) = \frac{2(3x^5 - 3x^4 + 5x^3 - 6x^2 + 3x + 4)}{(x^3 - x^2 - 4x + 1)^3}$$

We estimate from the graph of f that $y = 0$ is a horizontal asymptote, and that there are vertical asymptotes at $x = -1.7$, $x = 0.24$, and $x = 2.46$. From the graph of f' , we estimate that f is increasing on $(-\infty, -1.7)$, $(-1.7, 0.24)$, and $(0.24, 1)$, and that f is decreasing on $(1, 2.46)$ and $(2.46, \infty)$. There is a local maximum value at $f(1) = -\frac{1}{3}$. From the graph of f'' , we estimate that f is CU on $(-\infty, -1.7)$, $(-0.506, 0.24)$, and $(2.46, \infty)$, and that f is CD on $(-1.7, -0.506)$ and $(0.24, 2.46)$. There is an inflection point at $(-0.506, -0.192)$.

6. $f(x) = \tan x + 5 \cos x \Rightarrow f'(x) = \sec^2 x - 5 \sin x \Rightarrow f''(x) = 2 \sec^2 x \tan x - 5 \cos x$. Since f is periodic with period 2π , and defined for all x except odd multiples of $\frac{\pi}{2}$, we graph f and its derivatives on $[-\frac{\pi}{2}, \frac{3\pi}{2}]$.

We estimate from the graph of f' that f is increasing on $(-\frac{\pi}{2}, 0.21)$, $(1.07, \frac{\pi}{2})$, $(\frac{\pi}{2}, 2.07)$, and $(2.93, \frac{3\pi}{2})$, and decreasing on $(0.21, 1.07)$ and $(2.07, 2.93)$. Local minimum values: $f(1.07) \approx 4.23$, $f(2.93) \approx -5.10$. Local maximum values: $f(0.21) \approx 5.10$, $f(2.07) \approx -4.23$.

From the graph of f'' , we estimate that f is CU on $(0.76, \frac{\pi}{2})$ and $(2.38, \frac{3\pi}{2})$, and CD on $(-\frac{\pi}{2}, 0.76)$ and $(\frac{\pi}{2}, 2.38)$. f has IP at $(0.76, 4.57)$ and $(2.38, -4.57)$.

7. $f(x) = x^2 - 4x + 7 \cos x$, $-4 \leq x \leq 4$. $f'(x) = 2x - 4 - 7 \sin x \Rightarrow f''(x) = 2 - 7 \cos x$.
 $f(x) = 0 \Leftrightarrow x \approx 1.10$; $f'(x) = 0 \Leftrightarrow x \approx -1.49, -1.07$, or 2.89 ; $f''(x) = 0 \Leftrightarrow x = \pm \cos^{-1}(\frac{2}{7}) \approx \pm 1.28$.

From the graphs of f' , we estimate that f is decreasing ($f' < 0$) on $(-4, -1.49)$, increasing on $(-1.49, -1.07)$, decreasing on $(-1.07, 2.89)$, and increasing on $(2.89, 4)$, with local minimum values $f(-1.49) \approx 8.75$ and $f(2.89) \approx -9.99$ and local maximum value $f(-1.07) \approx 8.79$ (notice the second graph of f). From the graph of f'' , we estimate that f is CU ($f'' > 0$) on $(-4, -1.28)$, CD on $(-1.28, 1.28)$, and CU on $(1.28, 4)$. There are inflection points at about $(-1.28, 8.77)$ and $(1.28, -1.48)$.

$$8. f(x) = \frac{\sin x}{x}, -2\pi \leq x \leq 2\pi. f'(x) = \frac{x \cos x - \sin x}{x^2} \Rightarrow$$

$$f''(x) = \frac{x^2(\cos x - x \sin x - \cos x) - (x \cos x - \sin x)(2x)}{(x^2)^2} = \frac{-x^2 \sin x - 2x \cos x + 2 \sin x}{x^3}$$

f is an even function with domain $(-\infty, 0) \cup (0, \infty)$. There is no y -intercept, but $\lim_{x \rightarrow 0} f(x) = 1$. The x -intercepts are $-2\pi, -\pi, 0, \pi$, and 2π . From the graph of f' , we estimate that f is decreasing on $(-2\pi, -4.49)$, increasing on $(-4.49, 0)$, decreasing on $(0, 4.49)$, and increasing on $(4.49, 2\pi)$. Thus, f has local minima of $f(\pm 4.49) \approx -0.22$. From the graph of f'' , we estimate that f is CD on $(-2\pi, -5.94)$, CU on $(-5.94, -2.08)$, CD on $(-2.08, 0)$ and $(0, 2.08)$, CU on $(2.08, 5.94)$, and CD on $(5.94, 2\pi)$. f has IPs at approximately $(\pm 5.94, -0.06)$ and $(\pm 2.08, 0.42)$.

$$9. f(x) = 8x^3 - 3x^2 - 10 \Rightarrow f'(x) = 24x^2 - 6x \Rightarrow f''(x) = 48x - 6$$

From the graphs, it appears that $f(x) = 8x^3 - 3x^2 - 10$ increases on $(-\infty, 0)$ and $(0.25, \infty)$ and decreases on $(0, 0.25)$; that f has a local maximum value of $f(0) = -10.0$ and a local minimum value of $f(0.25) \approx -10.1$; that f is CU on $(0.1, \infty)$ and CD on $(-\infty, 0.1)$; and that f has an IP at $(0.1, -10)$. To find the exact values, note that $f'(x) = 24x^2 - 6x = 6x(4x - 1)$, which is positive (f is increasing) for $(-\infty, 0)$ and $(\frac{1}{4}, \infty)$, and negative (f is decreasing) on $(0, \frac{1}{4})$. By the FDT, f has a local maximum at $x = 0$: $f(0) = -10$; and f has a local minimum at $\frac{1}{4}$: $f(\frac{1}{4}) = \frac{1}{8} - \frac{3}{16} - 10 = -\frac{161}{16}$. $f''(x) = 48x - 6 = 6(8x - 1)$, which is positive (f is CU) on $(\frac{1}{8}, \infty)$ and negative (f is CD) on $(-\infty, \frac{1}{8})$. f has an IP at $(\frac{1}{8}, f(\frac{1}{8})) = (\frac{1}{8}, -\frac{321}{32})$.

10.

From the graphs, it appears that f increases on $(0, 3.6)$ and decreases on $(-\infty, 0)$ and $(3.6, \infty)$; that f has a local

maximum of $f(3.6) \approx 2.5$ and no local minima; that f is CU on $(5.5, \infty)$ and CD on $(-\infty, 0)$ and $(0, 5.5)$; and

that f has an IP at $(5.5, 2.3)$. $f(x) = \frac{x^2 + 11x - 20}{x^2} = 1 + \frac{11}{x} - \frac{20}{x^2} \Rightarrow$

$f'(x) = -11x^{-2} + 40x^{-3} = -x^{-3}(11x - 40)$, which is positive (f is increasing) on $(0, \frac{40}{11})$, and negative (f is decreasing) on $(-\infty, 0)$ and on $(\frac{40}{11}, \infty)$. By the FDT, f has a local maximum at $x = \frac{40}{11}$:

$f(\frac{40}{11}) = \frac{(\frac{40}{11})^2 + 11(\frac{40}{11}) - 20}{(\frac{40}{11})^2} = \frac{1600 + 11 \cdot 11 \cdot 40 - 20 \cdot 121}{1600} = \frac{201}{80}$; and f has no local minimum.

$f'(x) = -11x^{-2} + 40x^{-3} \Rightarrow f''(x) = 22x^{-3} - 120x^{-4} = 2x^{-4}(11x - 60)$, which is positive (f is CU) on $(\frac{60}{11}, \infty)$, and negative (f is CD) on $(-\infty, 0)$ and $(0, \frac{60}{11})$. f has an IP at $(\frac{60}{11}, f(\frac{60}{11})) = (\frac{60}{11}, \frac{211}{90})$.

11. From the graph, it appears that f increases on $(-2.1, 2.1)$ and decreases on $(-3, -2.1)$ and $(2.1, 3)$; that f has a local maximum of $f(2.1) \approx 4.5$ and a local minimum of $f(-2.1) \approx -4.5$; that f is CU on $(-3, 0)$ and CD on $(0, 3)$, and that f has an IP at $(0, 0)$. $f(x) = x\sqrt{9-x^2} \Rightarrow$

$f'(x) = \frac{-x^2}{\sqrt{9-x^2}} + \sqrt{9-x^2} = \frac{9-2x^2}{\sqrt{9-x^2}}$, which is positive

(f is increasing) on $(-\frac{3\sqrt{2}}{2}, \frac{3\sqrt{2}}{2})$ and negative (f is decreasing) on $(-3, -\frac{3\sqrt{2}}{2})$ and $(\frac{3\sqrt{2}}{2}, 3)$. By the FDT,

f has a local maximum value of $f(\frac{3\sqrt{2}}{2}) = \frac{3\sqrt{2}}{2} \sqrt{9 - (\frac{3\sqrt{2}}{2})^2} = \frac{9}{2}$; and f has a local minimum value of

$f(-\frac{3\sqrt{2}}{2}) = -\frac{9}{2}$ (since f is an odd function). $f'(x) = \frac{-x^2}{\sqrt{9-x^2}} + \sqrt{9-x^2} \Rightarrow$

$$f''(x) = \frac{\sqrt{9-x^2}(-2x) + x^2(\frac{1}{2})(9-x^2)^{-1/2}(-2x)}{9-x^2} - x(9-x^2)^{-1/2} = \frac{-2x - x^3(9-x^2)^{-1} - x}{\sqrt{9-x^2}}$$

$$= \frac{-3x}{\sqrt{9-x^2}} - \frac{x^3}{(9-x^2)^{3/2}} = \frac{x(2x^2-27)}{(9-x^2)^{3/2}}$$

which is positive (f is CU) on $(-3, 0)$ and negative (f is CD) on $(0, 3)$. f has an IP at $(0, 0)$.

12. From the graph, it appears that f increases on $(-5.2, -1.0)$ and $(1.0, 5.2)$ and decreases on $(-2\pi, -5.2)$, $(-1.0, 1.0)$, and $(5.2, 2\pi)$; that f has local maximum values of $f(-1.0) \approx 0.7$ and $f(5.2) \approx 7.0$ and local minimum values of $f(-5.2) \approx -7.0$ and $f(1.0) \approx -0.7$; that f is CU on $(-2\pi, -3.1)$ and $(0, 3.1)$ and CD on $(-3.1, 0)$ and $(3.1, 2\pi)$, and that f has IP at $(0, 0)$, $(-3.1, -3.1)$ and $(3.1, 3.1)$. $f(x) = x - 2\sin x \Rightarrow$

$f'(x) = 1 - 2\cos x$, which is positive (f is increasing) when $\cos x < \frac{1}{2}$, that is, on $(-\frac{5\pi}{3}, -\frac{\pi}{3})$ and $(\frac{\pi}{3}, \frac{5\pi}{3})$, and negative (f is decreasing) on $(-2\pi, -\frac{5\pi}{3})$, $(-\frac{\pi}{3}, \frac{\pi}{3})$, and $(\frac{5\pi}{3}, 2\pi)$. By the FDT, f has local maximum values

of $f(-\frac{\pi}{3}) = \frac{\pi}{3} + \sqrt{3}$ and $f(\frac{5\pi}{3}) = \frac{5\pi}{3} + \sqrt{3}$, and local minimum values of $f(-\frac{5\pi}{3}) = -\frac{5\pi}{3} - \sqrt{3}$ and

$f(\frac{\pi}{3}) = \frac{\pi}{3} - \sqrt{3}$. $f'(x) = 1 - 2\cos x \Rightarrow f''(x) = 2\sin x$, which is positive (f is CU) on $(-2\pi, -\pi)$ and $(0, \pi)$ and negative (f is CD) on $(-\pi, 0)$ and $(\pi, 2\pi)$. f has IP at $(0, 0)$, $(-\pi, -\pi)$ and (π, π) .

13.

$f(x) = \frac{(x+4)(x-3)^2}{x^4(x-1)}$ has VA at $x = 0$ and at $x = 1$ since

$$\lim_{x \rightarrow 0} f(x) = -\infty, \lim_{x \rightarrow 1^-} f(x) = -\infty \text{ and } \lim_{x \rightarrow 1^+} f(x) = \infty.$$

$$\begin{aligned} f(x) &= \frac{\frac{x+4}{x^4} \cdot \frac{(x-3)^2}{x^2}}{\frac{x-1}{x^3}} \quad \left[\text{dividing numerator and denominator by } x^3 \right] \\ &= \frac{(1+4/x)(1-3/x)^2}{x(x-1)} \rightarrow 0 \text{ as } x \rightarrow \pm\infty, \text{ so } f \text{ is asymptotic} \end{aligned}$$

to the x -axis. Since f is undefined at $x = 0$, it has no y -intercept. $f(x) = 0 \Rightarrow (x+4)(x-3)^2 = 0 \Rightarrow x = -4$ or $x = 3$, so f has x -intercepts -4 and 3 . Note, however, that the graph of f is only tangent to the x -axis and does not cross it at $x = 3$, since f is positive as $x \rightarrow 3^-$ and as $x \rightarrow 3^+$.

From these graphs, it appears that f has three maximum values and one minimum value. The maximum values are approximately $f(-5.6) = 0.0182$, $f(0.82) = -281.5$ and $f(5.2) = 0.0145$ and we know (since the graph is tangent to the x -axis at $x = 3$) that the minimum value is $f(3) = 0$.

14.

$f(x) = \frac{10x(x-1)^4}{(x-2)^3(x+1)^2}$ has VA at $x = -1$ and at $x = 2$ since

$$\lim_{x \rightarrow -1} f(x) = \infty, \lim_{x \rightarrow 2^-} f(x) = -\infty \text{ and } \lim_{x \rightarrow 2^+} f(x) = \infty.$$

$$f(x) = \frac{10(1-1/x)^4}{(1-2/x)^3(1+1/x)^2} \rightarrow 10 \text{ as } x \rightarrow \pm\infty, \text{ so } f \text{ is asymptotic to}$$

the line $y = 10$. $f(0) = 0$, so f has a y -intercept at 0 . $f(x) = 0 \Rightarrow$

$$10x(x-1)^4 = 0 \Rightarrow x = 0 \text{ or } x = 1. \text{ So } f \text{ has } x\text{-intercepts } 0 \text{ and } 1.$$

Note, however, that f does not change sign at $x = 1$, so the graph is tangent to the x -axis and does not cross it.

We know (since the graph is tangent to the x -axis at $x = 1$) that the maximum value is $f(1) = 0$. From the graphs it appears that the minimum value is about $f(0.2) = -0.1$.

15. $f(x) = \frac{x^2(x+1)^3}{(x-2)^3(x+4)^4} \Rightarrow f'(x) = -\frac{x(x+1)^2(x^3+18x^2-44x-16)}{(x-2)^3(x+4)^5}$ (from CAS).

From the graphs of f' , it seems that the critical points which indicate extrema occur at $x \approx -20, -0.3$, and 2.5 , as estimated in Example 3. (There is another critical point at $x = -1$, but the sign of f' does not change there.)

We differentiate again, obtaining $f''(x) = 2 \frac{(x+1)(x^6+36x^5+6x^4-628x^3+684x^2+672x+64)}{(x-2)^4(x+4)^6}$.

From the graphs of f'' , it appears that f is CU on $(-35.3, -5.0)$, $(-1, -0.5)$, $(-0.1, 2)$, $(2, 4)$ and $(4, \infty)$ and CD on $(-\infty, -35.3)$, $(-5.0, -1)$ and $(-0.5, -0.1)$. We check back on the graphs of f to find the y -coordinates of the inflection points, and find that these points are approximately $(-35.3, -0.015)$, $(-5.0, -0.005)$, $(-1, 0)$, $(-0.5, 0.00001)$, and $(-0.1, 0.000066)$.

16. $f(x) = \frac{10x(x-1)^4}{(x-2)^3(x+1)^2} \Rightarrow f'(x) = -20 \frac{(x-1)^3(5x-1)}{(x-2)^4(x+1)^3}$ (from CAS).

From the graphs of f' , we estimate that f is increasing on $(-\infty, -1)$ and $(0.2, 1)$ and decreasing on $(-1, 0.2)$, $(1, 2)$ and $(2, \infty)$. Differentiating $f'(x)$, we get $f''(x) = 60 \frac{(x-1)^2(5x^3-8x^2+17x-6)}{(x-2)^5(x+1)^4}$.

From the graphs of f'' , it seems that f is CU on $(-\infty, -1.0)$, $(-1.0, 0.4)$ and $(2.0, \infty)$, and CD on $(0.4, 2)$. There is an inflection point at about $(0.4, -0.06)$.

17. $y = f(x) = \frac{\sin^2 x}{\sqrt{x^2 + 1}}$ with $0 \leq x \leq 3\pi$. From a CAS, $y' = \frac{\sin x [2(x^2 + 1) \cos x - x \sin x]}{(x^2 + 1)^{3/2}}$ and

$$y'' = \frac{(4x^4 + 6x^2 + 5)\cos^2 x - 4x(x^2 + 1)\sin x \cos x - 2x^4 - 2x^2 - 3}{(x^2 + 1)^{5/2}}.$$

From the graph of f' and the formula for y' , we determine that $y' = 0$ when $x = \pi, 2\pi, 3\pi$, or $x \approx 1.3, 4.6$, or 7.8 . So f is increasing on $(0, 1.3)$, $(\pi, 4.6)$, and $(2\pi, 7.8)$. f is decreasing on $(1.3, \pi)$, $(4.6, 2\pi)$, and $(7.8, 3\pi)$. Local maximum values: $f(1.3) \approx 0.6$, $f(4.6) \approx 0.21$, and $f(7.8) \approx 0.13$. Local minimum values: $f(\pi) = f(2\pi) = 0$. From the graph of f'' , we see that $y'' = 0 \Leftrightarrow x \approx 0.6, 2.1, 3.8, 5.4, 7.0$, or 8.6 . So f is CU on $(0, 0.6)$, $(2.1, 3.8)$, $(5.4, 7.0)$, and $(8.6, 3\pi)$. f is CD on $(0.6, 2.1)$, $(3.8, 5.4)$, and $(7.0, 8.6)$. There are IP at $(0.6, 0.25)$, $(2.1, 0.31)$, $(3.8, 0.10)$, $(5.4, 0.11)$, $(7.0, 0.061)$, and $(8.6, 0.065)$.

18. $f(x) = \frac{2x - 1}{\sqrt[3]{x^4 + x + 1}} \Rightarrow$

$$f'(x) = \frac{4x^3 + 6x + 9}{4(x^4 + x + 1)^{5/4}} \Rightarrow$$

$$f''(x) = -\frac{32x^6 + 96x^4 + 152x^3 - 48x^2 + 6x + 21}{16(x^4 + x + 1)^{9/4}}$$

From the graph of f' , f appears to be decreasing on $(-\infty, -0.94)$ and increasing on $(-0.94, \infty)$. There is a local minimum value of $f(-0.94) \approx -3.01$. From the graph of f'' , f appears to be CU on $(-1.25, -0.44)$ and CD on $(-\infty, -1.25)$ and $(-0.44, \infty)$. There are inflection points at $(-1.25, -2.87)$ and $(-0.44, -2.14)$.

From the graph of $f(x) = \sin(x + \sin 3x)$ in the viewing rectangle $[0, \pi]$ by $[-1.2, 1.2]$, it looks like f has two maxima and two minima. If we calculate and graph $f'(x) = [\cos(x + \sin 3x)](1 + 3 \cos 3x)$ on $[0, 2\pi]$, we see that the graph of f' appears to be almost tangent to the x -axis at about $x = 0.7$. The graph of $f'' = -[\sin(x + \sin 3x)](1 + 3 \cos 3x)^2 + \cos(x + \sin 3x)(-9 \sin 3x)$ is even more interesting near this x -value: it seems to just touch the x -axis.

If we zoom in on this place on the graph of f'' , we see that f'' actually does cross the axis twice near $x = 0.65$, indicating a change in concavity for a very short interval. If we look at the graph of f' on the same interval, we see that it changes sign three times near $x = 0.65$, indicating that what we had thought was a broad extremum at about $x = 0.7$ actually consists of three extrema (two maxima and a minimum). These maximum values are roughly $f(0.59) = 1$ and $f(0.68) = 1$, and the minimum value is roughly $f(0.64) = 0.99996$. There are also a maximum value of about $f(1.96) = 1$ and minimum values of about $f(1.46) = 0.49$ and $f(2.73) = -0.51$. The points of inflection on $(0, \pi)$ are about $(0.61, 0.99998)$, $(0.66, 0.99998)$, $(1.17, 0.72)$, $(1.75, 0.77)$, and $(2.28, 0.34)$. On $(\pi, 2\pi)$, they are about $(4.01, -0.34)$, $(4.54, -0.77)$, $(5.11, -0.72)$, $(5.62, -0.99998)$, and $(5.67, -0.99998)$. There are also IP at $(0, 0)$ and $(\pi, 0)$. Note that the function is odd and periodic with period 2π , and it is also rotationally symmetric about all points of the form $((2n + 1)\pi, 0)$, n an integer.

20. $f(x) = x^3 + cx = x(x^2 + c) \Rightarrow f'(x) = 3x^2 + c \Rightarrow f''(x) = 6x$

x -intercepts: When $c \geq 0$, 0 is the only x -intercept. When $c < 0$, the x -intercepts are 0 and $\pm\sqrt{-c}$.

y -intercept = $f(0) = 0$. f is odd, so the graph is symmetric with respect to the origin. $f''(x) < 0$ for $x < 0$ and $f''(x) > 0$ for $x > 0$, so f is CD on $(-\infty, 0)$ and CU on $(0, \infty)$. The origin is the only inflection point.

If $c > 0$, then $f'(x) > 0$ for all x , so f is increasing and has no local maximum or minimum.

If $c = 0$, then $f'(x) \geq 0$ with equality at $x = 0$, so again f is increasing and has no local maximum or minimum.

If $c < 0$, then $f'(x) = 3[x^2 - (-c/3)] = 3(x + \sqrt{-c/3})(x - \sqrt{-c/3})$,

so $f'(x) > 0$ on $(-\infty, -\sqrt{-c/3})$ and $(\sqrt{-c/3}, \infty)$; $f'(x) < 0$ on

$(-\sqrt{-c/3}, \sqrt{-c/3})$. It follows that $f(-\sqrt{-c/3}) = -\frac{2}{3}c\sqrt{-c/3}$ is

a local maximum value and $f(\sqrt{-c/3}) = \frac{2}{3}c\sqrt{-c/3}$ is a local

minimum value. As c decreases (toward more negative values), the local maximum and minimum move further apart.

There is no absolute maximum or minimum value. The only transitional value of c corresponding to a change in character of the graph is $c = 0$.

21. $f(x) = x^4 + cx^2 = x^2(x^2 + c)$. Note that f is an even function. For $c \geq 0$, the only x -intercept is the point $(0, 0)$.

We calculate $f'(x) = 4x^3 + 2cx = 4x(x^2 + \frac{1}{2}c) \Rightarrow f''(x) = 12x^2 + 2c$. If $c \geq 0$, $x = 0$ is the only critical point and there is no inflection point. As we can see from the examples, there is no change in the basic shape of the graph for $c \geq 0$; it merely becomes steeper as c increases. For $c = 0$, the graph is the simple curve

$y = x^4$. For $c < 0$, there are x -intercepts at 0 and at $\pm\sqrt{-c}$. Also,

there is a maximum at $(0, 0)$, and there are minima at

$(\pm\sqrt{-\frac{1}{2}c}, -\frac{1}{4}c^2)$. As $c \rightarrow -\infty$, the x -coordinates of these minima

get larger in absolute value, and the minimum points move

downward. There are inflection points at $(\pm\sqrt{-\frac{1}{6}c}, -\frac{5}{36}c^2)$, which

also move away from the origin as $c \rightarrow -\infty$.

22. We need only consider the function $f(x) = x^2\sqrt{c^2 - x^2}$ for $c \geq 0$, because if c is replaced by $-c$, the function is unchanged. For $c = 0$, the graph consists of the single point $(0, 0)$. The domain of f is $[-c, c]$, and the graph of f is symmetric about the y -axis.

$$f'(x) = 2x\sqrt{c^2 - x^2} + x^2 \frac{-2x}{2\sqrt{c^2 - x^2}} = 2x\sqrt{c^2 - x^2} - \frac{x^3}{\sqrt{c^2 - x^2}} = \frac{2x(c^2 - x^2) - x^3}{\sqrt{c^2 - x^2}} = -\frac{3x(x^2 - \frac{2}{3}c^2)}{\sqrt{c^2 - x^2}}.$$

So we see that all members of the family of curves have horizontal tangents at $x = 0$, since $f'(0) = 0$ for all $c > 0$.

Also, the tangents to all the curves become very steep as $x \rightarrow \pm c$, since $\lim_{x \rightarrow -c^+} f'(x) = \infty$ and

$\lim_{x \rightarrow c^-} f'(x) = -\infty$. We set $f'(x) = 0 \Leftrightarrow x = 0$ or $x^2 - \frac{2}{3}c^2 = 0$, so the absolute maximum values

are $f(\pm\sqrt{\frac{2}{3}c}) = \frac{2}{3\sqrt{3}}c^3$.

$$f''(x) = \frac{(-9x^2 + 2c^2)\sqrt{c^2 - x^2} - (-3x^3 + 2c^2x)(-x/\sqrt{c^2 - x^2})}{c^2 - x^2} = \frac{6x^4 - 9c^2x^2 + 2c^4}{(c^2 - x^2)^{3/2}}.$$

Using the quadratic formula, we find that $f''(x) = 0 \Leftrightarrow x^2 = \frac{9c^2 \pm c^2\sqrt{33}}{12}$. Since $-c < x < c$, we take

$x^2 = \frac{9 - \sqrt{33}}{12}c^2$, so the inflection points are $(\pm\sqrt{\frac{9 - \sqrt{33}}{12}}c, \frac{(9 - \sqrt{33})(\sqrt{33} - 3)}{144}c^3)$.

From these calculations we can see that the maxima and the points of inflection get both horizontally and vertically further from the origin as c increases. Since all of the functions have two maxima and two inflection points, we see that the basic shape of the curve does not change as c changes.

23. Note that $c = 0$ is a transitional value at which the graph consists of the x -axis. Also, we can see that if we

substitute $-c$ for c , the function $f(x) = \frac{cx}{1 + c^2x^2}$ will be reflected in the x -axis, so we investigate only positive

values of c (except $c = -1$, as a demonstration of this reflective property). Also, f is an odd function. $\lim_{x \rightarrow \pm\infty} f(x) = 0$, so $y = 0$ is a horizontal asymptote for all c . We calculate

$$f'(x) = \frac{(1 + c^2 x^2)c - cx(2c^2 x)}{(1 + c^2 x^2)^2} = -\frac{c(c^2 x^2 - 1)}{(1 + c^2 x^2)^2}. \quad f'(x) = 0 \Leftrightarrow c^2 x^2 - 1 = 0 \Leftrightarrow x = \pm 1/c. \text{ So there}$$

is an absolute maximum value of $f(1/c) = \frac{1}{2}$ and an absolute minimum value of $f(-1/c) = -\frac{1}{2}$. These extrema have the same value regardless of c , but the maximum points move closer to the y -axis as c increases.

$$\begin{aligned} f''(x) &= \frac{(-2c^3 x)(1 + c^2 x^2)^2 - (-c^3 x^2 + c)[2(1 + c^2 x^2)(2c^2 x)]}{(1 + c^2 x^2)^4} \\ &= \frac{(-2c^3 x)(1 + c^2 x^2) + (c^3 x^2 - c)(4c^2 x)}{(1 + c^2 x^2)^3} = \frac{2c^3 x(c^2 x^2 - 3)}{(1 + c^2 x^2)^3} \end{aligned}$$

$f''(x) = 0 \Leftrightarrow x = 0$ or $\pm\sqrt{3}/c$, so there are inflection points at $(0, 0)$ and at $(\pm\sqrt{3}/c, \pm\sqrt{3}/4)$.

Again, the y -coordinate of the inflection points does not depend on c , but as c increases, both inflection points approach the y -axis.

24. Note that $f(x) = \frac{1}{(1-x^2)^2 + cx^2}$ is an even function, and also that $\lim_{x \rightarrow \pm\infty} f(x) = 0$ for any value of c , so $y = 0$

is a horizontal asymptote. We calculate the derivatives:

$$\begin{aligned} f'(x) &= \frac{-4(1-x^2)x + 2cx}{[(1-x^2)^2 + cx^2]^2} = \frac{4x[x^2 + (\frac{1}{2}c - 1)]}{[(1-x^2)^2 + cx^2]^2}, \text{ and} \\ f''(x) &= 2 \frac{10x^6 + (9c-18)x^4 + (3c^2-12c+6)x^2 + 2-c}{[x^4 + (c-2)x^2 + 1]^3}. \end{aligned}$$

We first consider the case $c > 0$. Then the denominator of f' is

positive, that is, $(1-x^2)^2 + cx^2 > 0$ for all x , so f has domain $\mathbb{R}$ and also $f > 0$. If $\frac{1}{2}c - 1 \geq 0$; that is, $c \geq 2$, then the only critical point is $f(0) = 1$, a maximum. Graphing a few examples for $c \geq 2$ shows that there are two IP which approach the y -axis as $c \rightarrow \infty$.

$c = 2$ and $c = 0$ are transitional values of c at which the shape of the curve changes. For $0 < c < 2$, there are three critical points: $f(0) = 1$, a minimum value, and $f(\pm\sqrt{1 - \frac{1}{2}c}) = \frac{1}{c(1 - c/4)}$, both maximum values. As c decreases from 2 to 0, the maximum values get larger and larger, and the x -values at which they occur go from 0 to ± 1 . Graphs show that there are four inflection points for $0 < c < 2$, and that they get farther away from the origin, both vertically and horizontally, as $c \rightarrow 0^+$. For $c = 0$, the function is simply asymptotic to the x -axis and to the lines $x = \pm 1$, approaching $+\infty$ from both sides of each. The y -intercept is 1, and $(0, 1)$ is a local minimum. There are no inflection points. Now if $c < 0$, we can write

$f(x) = \frac{1}{(1-x^2)^2 + cx^2} = \frac{1}{(1-x^2)^2 - (\sqrt{-c}x)^2} = \frac{1}{(x^2 - \sqrt{-c}x - 1)(x^2 + \sqrt{-c}x - 1)}$. So f has vertical asymptotes where $x^2 \pm \sqrt{-c}x - 1 = 0 \Leftrightarrow x = (-\sqrt{-c} \pm \sqrt{4-c})/2$ or $x = (\sqrt{-c} \pm \sqrt{4-c})/2$. As c

decreases, the two exterior asymptotes move away from the origin, while the two interior ones move toward it. We graph a few examples to see the behavior of the graph near the asymptotes, and the nature of the critical points

$$x = 0 \text{ and } x = \pm\sqrt{1 - \frac{1}{2}c}:$$

We see that there is one local minimum value, $f(0) = 1$, and there are two local maximum values,

$f\left(\pm\sqrt{1 - \frac{1}{2}c}\right) = \frac{1}{c(1 - c/4)}$ as before. As c decreases, the x -values at which these maxima occur get larger, and the maximum values themselves approach 0, though they are always negative.

25. $f(x) = cx + \sin x \Rightarrow f'(x) = c + \cos x \Rightarrow f''(x) = -\sin x$

$f(-x) = -f(x)$, so f is an odd function and its graph is symmetric with respect to the origin.

$$f(x) = 0 \Leftrightarrow \sin x = -cx, \text{ so } 0 \text{ is always an } x\text{-intercept.}$$

$f'(x) = 0 \Leftrightarrow \cos x = -c$, so there is no critical number when $|c| > 1$. If $|c| \leq 1$, then there are infinitely many critical numbers. If x_1 is the unique solution of $\cos x = -c$ in the interval $[0, \pi]$, then the critical numbers are $2n\pi \pm x_1$, where n ranges over the integers. (Special cases: When $c = 1$, $x_1 = 0$; when $c = 0$, $x = \frac{\pi}{2}$; and when $c = -1$, $x_1 = \pi$.)

$f''(x) < 0 \Leftrightarrow \sin x > 0$, so f is CD on intervals of the form $(2n\pi, (2n+1)\pi)$. f is CU on intervals of the form $((2n-1)\pi, 2n\pi)$. The inflection points of f are the points $(2n\pi, 2n\pi c)$, where n is an integer.

If $c \geq 1$, then $f'(x) \geq 0$ for all x , so f is increasing and has no extremum. If $c \leq -1$, then $f'(x) \leq 0$ for all x , so f is decreasing and has no extremum. If $|c| < 1$, then $f'(x) > 0 \Leftrightarrow \cos x > -c \Leftrightarrow x$ is in an interval of the form $(2n\pi - x_1, 2n\pi + x_1)$ for some integer n . These are the intervals on which f is increasing. Similarly, we find that f is decreasing on the intervals of the form $(2n\pi + x_1, 2(n+1)\pi - x_1)$. Thus, f has local maxima at the points $2n\pi + x_1$, where f has the values $c(2n\pi + x_1) + \sin x_1 = c(2n\pi + x_1) + \sqrt{1 - c^2}$, and f has local minima at the points $2n\pi - x_1$, where we have $f(2n\pi - x_1) = c(2n\pi - x_1) - \sin x_1 = c(2n\pi - x_1) - \sqrt{1 - c^2}$.

The transitional values of c are -1 and 1 . The inflection points move vertically, but not horizontally, when c changes. When $|c| \geq 1$, there is no extremum. For $|c| < 1$, the maxima are spaced 2π apart horizontally, as are the minima. The horizontal spacing between maxima and adjacent minima is regular (and equals π) when $c = 0$, but the horizontal space between a local maximum and the nearest local minimum shrinks as $|c|$ approaches 1.

26. For $c = 0$, there is no inflection point; the curve is CU everywhere. If c increases, the curve simply becomes steeper, and there are still no inflection points. If c starts at 0 and decreases, a slight upward bulge appears near $x = 0$, so that there are two inflection points for any $c < 0$. This can be seen algebraically by calculating the second derivative: $f(x) = x^4 + cx^2 + x \Rightarrow f'(x) = 4x^3 + 2cx + 1 \Rightarrow f''(x) = 12x^2 + 2c$. Thus, $f''(x) > 0$ when $c > 0$. For $c < 0$, there are inflection points when $x = \pm\sqrt{-\frac{1}{6}c}$. For $c = 0$, the graph has one critical number, at the absolute minimum somewhere around $x = -0.6$. As c increases, the number of critical points does not change. If c instead decreases from 0, we see that the graph eventually sprouts another local minimum, to the right of the origin, somewhere between $x = 1$ and $x = 2$. Consequently, there is also a maximum near $x = 0$. After a bit of experimentation, we find that at $c = -1.5$, there appear to be two critical numbers: the absolute minimum at about $x = -1$, and a horizontal tangent with no extremum at about $x = 0.5$. For any c smaller than this there will be 3 critical points, as shown in the graphs with $c = -3$ and with $c = -5$. To prove this algebraically, we calculate $f'(x) = 4x^3 + 2cx + 1$. Now if we substitute our value of $c = -1.5$, the formula for $f'(x)$ becomes $4x^3 - 3x + 1 = (x + 1)(2x - 1)^2$. This has a double root at $x = \frac{1}{2}$, indicating that the function has two critical points: $x = -1$ and $x = \frac{1}{2}$, just as we had guessed from the graph.

27. (a) $f(x) = cx^4 - 2x^2 + 1$. For $c = 0$, $f(x) = -2x^2 + 1$, a parabola whose vertex, $(0, 1)$, is the absolute maximum. For $c > 0$, $f(x) = cx^4 - 2x^2 + 1$ opens upward with two minimum points. As $c \rightarrow 0$, the minimum points spread apart and move downward; they are below the x -axis for $0 < c < 1$ and above for $c > 1$. For $c < 0$, the graph opens downward, and has an absolute maximum at $x = 0$ and no local minimum.

- (b) $f'(x) = 4cx^3 - 4x = 4cx(x^2 - 1/c)$ ($c \neq 0$). If $c \leq 0$, 0 is the only critical number. $f''(x) = 12cx^2 - 4$, so $f''(0) = -4$ and there is a local maximum at $(0, f(0)) = (0, 1)$, which lies on $y = 1 - x^2$. If $c > 0$, the critical numbers are 0 and $\pm 1/\sqrt{c}$. As before, there is a local maximum at $(0, f(0)) = (0, 1)$, which lies on $y = 1 - x^2$. $f''(\pm 1/\sqrt{c}) = 12 - 4 = 8 > 0$, so there is a local minimum at $x = \pm 1/\sqrt{c}$. Here $f(\pm 1/\sqrt{c}) = c(1/c^2) - 2/c + 1 = -1/c + 1$. But $(\pm 1/\sqrt{c}, -1/c + 1)$ lies on $y = 1 - x^2$ since $1 - (\pm 1/\sqrt{c})^2 = 1 - 1/c$.

28. (a) $f(x) = 2x^3 + cx^2 + 2x \Rightarrow f'(x) = 6x^2 + 2cx + 2 = 2(3x^2 + cx + 1)$. $f'(x) = 0 \Leftrightarrow x = \frac{-c \pm \sqrt{c^2 - 12}}{6}$. So f has critical points $\Leftrightarrow c^2 - 12 \geq 0 \Leftrightarrow |c| \geq 2\sqrt{3}$. For $c = \pm 2\sqrt{3}$, $f'(x) \geq 0$ on $(-\infty, \infty)$, so f' does not change signs at $-c/6$, and there is no extremum. If $c^2 - 12 > 0$, then

f' changes from positive to negative at $x = \frac{-c - \sqrt{c^2 - 12}}{6}$ and from negative to positive at $x = \frac{-c + \sqrt{c^2 - 12}}{6}$. So f has a local maximum at $x = \frac{-c - \sqrt{c^2 - 12}}{6}$ and a local minimum at $x = \frac{-c + \sqrt{c^2 - 12}}{6}$.

(b) Let x_0 be a critical number for $f(x)$. Then $f'(x_0) = 0 \Rightarrow$

$$3x_0^2 + cx_0 + 1 = 0 \Leftrightarrow c = \frac{-1 - 3x_0^2}{x_0}. \text{ Now}$$

$$\begin{aligned} f(x_0) &= 2x_0^3 + cx_0^2 + 2x_0 = 2x_0^3 + x_0^2 \left(\frac{-1 - 3x_0^2}{x_0} \right) + 2x_0 \\ &= 2x_0^3 - x_0 - 3x_0^3 + 2x_0 = x_0 - x_0^3 \end{aligned}$$

So the point is $(x_0, y_0) = (x_0, x_0 - x_0^3)$; that is, the point lies on the curve $y = x - x^3$.

4.7 Optimization Problems

1. (a)

First Number	Second Number	Product
1	22	22
2	21	42
3	20	60
4	19	76
5	18	90
6	17	102
7	16	112
8	15	120
9	14	126
10	13	130
11	12	132

We needn't consider pairs where the first number is larger than the second, since we can just interchange the numbers in such cases. The answer appears to be 11 and 12, but we have considered only integers in the table.

(b) Call the two numbers x and y . Then $x + y = 23$, so $y = 23 - x$. Call the product P . Then

$P = xy = x(23 - x) = 23x - x^2$, so we wish to maximize the function $P(x) = 23x - x^2$. Since

$P'(x) = 23 - 2x$, we see that $P'(x) = 0 \Leftrightarrow x = \frac{23}{2} = 11.5$. Thus, the maximum value of P is

$P(11.5) = (11.5)^2 = 132.25$ and it occurs when $x = y = 11.5$.

Or: Note that $P''(x) = -2 < 0$ for all x , so P is everywhere concave downward and the local maximum at $x = 11.5$ must be an absolute maximum.

2. The two numbers are $x + 100$ and x . Minimize $f(x) = (x + 100)x = x^2 + 100x$. $f'(x) = 2x + 100 = 0 \Rightarrow x = -50$. Since $f''(x) = 2 > 0$, there is an absolute minimum at $x = -50$. The two numbers are 50 and -50 .
3. The two numbers are x and $\frac{100}{x}$, where $x > 0$. Minimize $f(x) = x + \frac{100}{x}$. $f'(x) = 1 - \frac{100}{x^2} = \frac{x^2 - 100}{x^2}$. The critical number is $x = 10$. Since $f'(x) < 0$ for $0 < x < 10$ and $f'(x) > 0$ for $x > 10$, there is an absolute minimum at $x = 10$. The numbers are 10 and 10.
4. Let $x > 0$ and let $f(x) = x + 1/x$. We wish to minimize $f(x)$. Now $f'(x) = 1 - \frac{1}{x^2} = \frac{1}{x^2}(x^2 - 1) = \frac{1}{x^2}(x + 1)(x - 1)$, so the only critical number in $(0, \infty)$ is 1. $f'(x) < 0$ for $0 < x < 1$ and $f'(x) > 0$ for $x > 1$, so f has an absolute minimum at $x = 1$, and $f(1) = 2$. Or: $f''(x) = 2/x^3 > 0$ for all $x > 0$, so f is concave upward everywhere and the critical point $(1, 2)$ must correspond to a local minimum for f .
5. If the rectangle has dimensions x and y , then its perimeter is $2x + 2y = 100$ m, so $y = 50 - x$. Thus, the area is $A = xy = x(50 - x)$. We wish to maximize the function $A(x) = x(50 - x) = 50x - x^2$, where $0 < x < 50$. Since $A'(x) = 50 - 2x = -2(x - 25)$, $A'(x) > 0$ for $0 < x < 25$ and $A'(x) < 0$ for $25 < x < 50$. Thus, A has an absolute maximum at $x = 25$, and $A(25) = 25^2 = 625$ m². The dimensions of the rectangle that maximize its area are $x = y = 25$ m. (The rectangle is a square.)
6. If the rectangle has dimensions x and y , then its area is $xy = 1000$ m², so $y = 1000/x$. The perimeter $P = 2x + 2y = 2x + 2000/x$. We wish to minimize the function $P(x) = 2x + 2000/x$ for $x > 0$. $P'(x) = 2 - 2000/x^2 = (2/x^2)(x^2 - 1000)$, so the only critical number in the domain of P is $x = \sqrt{1000}$. $P''(x) = 4000/x^3 > 0$, so P is concave upward throughout its domain and $P(\sqrt{1000}) = 4\sqrt{1000}$ is an absolute minimum value. The dimensions of the rectangle with minimal perimeter are $x = y = \sqrt{1000} = 10\sqrt{10}$ m. (The rectangle is a square.)

7. (a)

The areas of the three figures are 12,500, 12,500, and 9000 ft². There appears to be a maximum area of at least 12,500 ft².

(b) Let x denote the length of each of two sides and three dividers.

Let y denote the length of the other two sides.

(c) Area $A = \text{length} \times \text{width} = y \cdot x$

(d) Length of fencing = 750 $\Rightarrow 5x + 2y = 750$

(e) $5x + 2y = 750 \Rightarrow y = 375 - \frac{5}{2}x \Rightarrow A(x) = (375 - \frac{5}{2}x)x = 375x - \frac{5}{2}x^2$

(f) $A'(x) = 375 - 5x = 0 \Rightarrow x = 75$. Since $A''(x) = -5 < 0$ there is an absolute maximum when $x = 75$.

Then $y = \frac{375}{2} = 187.5$. The largest area is $75(\frac{375}{2}) = 14,062.5$ ft². These values of x and y are between the values in the first and second figures in part (a). Our original estimate was low.

8. (a)

The volumes of the resulting boxes are 1, 1.6875, and 2 ft^3 . There appears to be a maximum volume of at least 2 ft^3 .

(c) Volume $V = \text{length} \times \text{width} \times \text{height} \Rightarrow V = y \cdot y \cdot x = xy^2$

(d) Length of cardboard = 3 $\Rightarrow x + y + x = 3 \Rightarrow y + 2x = 3$

(e) $y + 2x = 3 \Rightarrow y = 3 - 2x \Rightarrow V(x) = x(3 - 2x)^2$

(f) $V(x) = x(3 - 2x)^2 \Rightarrow$

$$V'(x) = x \cdot 2(3 - 2x)(-2) + (3 - 2x)^2 \cdot 1 = (3 - 2x)[-4x + (3 - 2x)] = (3 - 2x)(-6x + 3),$$

so the critical numbers are $x = \frac{3}{2}$ and $x = \frac{1}{2}$. Now $0 \leq x \leq \frac{3}{2}$ and $V(0) = V(\frac{3}{2}) = 0$, so the maximum is

$$V(\frac{1}{2}) = (\frac{1}{2})(2)^2 = 2 \text{ ft}^3, \text{ which is the value found from our third figure in part (a).}$$

9.

$xy = 1.5 \times 10^6$, so $y = 1.5 \times 10^6/x$. Minimize the amount of fencing, which is $3x + 2y = 3x + 2(1.5 \times 10^6/x) = 3x + 3 \times 10^6/x = F(x)$.

$F'(x) = 3 - 3 \times 10^6/x^2 = 3(x^2 - 10^6)/x^2$. The critical number is $x = 10^3$ and $F'(x) < 0$ for $0 < x < 10^3$ and $F'(x) > 0$ if $x > 10^3$, so the absolute minimum occurs when $x = 10^3$ and $y = 1.5 \times 10^3$.

The field should be 1000 feet by 1500 feet with the middle fence parallel to the short side of the field.

10. Let b be the length of the base of the box and h the height. The volume is $32,000 = b^2h \Rightarrow h = 32,000/b^2$.

The surface area of the open box is $S = b^2 + 4hb = b^2 + 4(32,000/b^2)b = b^2 + 4(32,000)/b$. So

$S'(b) = 2b - 4(32,000)/b^2 = 2(b^3 - 64,000)/b^2 = 0 \Leftrightarrow b = \sqrt[3]{64,000} = 40$. This gives an absolute minimum since $S'(b) < 0$ if $0 < b < 40$ and $S'(b) > 0$ if $b > 40$. The box should be $40 \times 40 \times 20$.

11. Let b be the length of the base of the box and h the height. The surface area is $1200 = b^2 + 4hb \Rightarrow h = (1200 - b^2)/(4b)$. The volume is $V = b^2h = b^2(1200 - b^2)/(4b) = 300b - b^3/4 \Rightarrow V'(b) = 300 - \frac{3}{4}b^2$.

$V'(b) = 0 \Rightarrow 300 = \frac{3}{4}b^2 \Rightarrow b^2 = 400 \Rightarrow b = \sqrt{400} = 20$. Since $V'(b) > 0$ for $0 < b < 20$ and $V'(b) < 0$ for $b > 20$, there is an absolute maximum when $b = 20$ by the First Derivative Test for Absolute Extreme Values (see page 280). If $b = 20$, then $h = (1200 - 20^2)/(4 \cdot 20) = 10$, so the largest possible volume is $b^2h = (20)^2(10) = 4000 \text{ cm}^3$.

12.

$V = lwh \Rightarrow 10 = (2w)(w)h = 2w^2h$, so $h = 5/w^2$. The cost is $10(2w^2) + 6[2(2wh) + 2(hw)] = 20w^2 + 36wh$, so

$$C(w) = 20w^2 + 36w(5/w^2) = 20w^2 + 180/w.$$

$$C'(w) = 40w - 180/w^2 = 40(w^3 - \frac{9}{2})/w^2 \Rightarrow w = \sqrt[3]{\frac{9}{2}} \text{ is the}$$

critical number. There is an absolute minimum for C when $w = \sqrt[3]{\frac{9}{2}}$ since $C'(w) < 0$ for $0 < w < \sqrt[3]{\frac{9}{2}}$ and

$$C'(w) > 0 \text{ for } w > \sqrt[3]{\frac{9}{2}}. \quad C\left(\sqrt[3]{\frac{9}{2}}\right) = 20\left(\sqrt[3]{\frac{9}{2}}\right)^2 + \frac{180}{\sqrt[3]{9/2}} \approx \$163.54.$$

(b) Let x denote the length of the side of the square being cut out. Let y denote the length of the base.

18.

The distance d from $(1, 1)$ to an arbitrary point $P(x, y)$ on the curve $y = \tan x$ is $d = \sqrt{(x-1)^2 + (y-1)^2}$ and the square of the distance is $S = d^2 = (x-1)^2 + (\tan x - 1)^2$.
 $S' = 2(x-1) + 2(\tan x - 1) \sec^2 x$. Graphing S' on $(-\frac{\pi}{2}, \frac{\pi}{2})$ gives us a zero at $x \approx 0.82$, and so $\tan x \approx 1.08$. The point on $y = \tan x$ that is closest to $(1, 1)$ is approximately $(0.82, 1.08)$.

19.

The area of the rectangle is $(2x)(2y) = 4xy$. Also $r^2 = x^2 + y^2$ so $y = \sqrt{r^2 - x^2}$, so the area is $A(x) = 4x\sqrt{r^2 - x^2}$. Now $A'(x) = 4\left(\sqrt{r^2 - x^2} - \frac{x^2}{\sqrt{r^2 - x^2}}\right) = 4\frac{r^2 - 2x^2}{\sqrt{r^2 - x^2}}$. The critical number is $x = \frac{1}{\sqrt{2}}r$. Clearly this gives a maximum.
 $y = \sqrt{r^2 - \left(\frac{1}{\sqrt{2}}r\right)^2} = \sqrt{\frac{1}{2}r^2} = \frac{1}{\sqrt{2}}r = x$, which tells us that the rectangle is a square. The dimensions are $2x = \sqrt{2}r$ and $2y = \sqrt{2}r$.

20.

The area of the rectangle is $(2x)(2y) = 4xy$. Now $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ gives $y = \frac{b}{a}\sqrt{a^2 - x^2}$, so we maximize $A(x) = 4\frac{b}{a}x\sqrt{a^2 - x^2}$.
 $A'(x) = \frac{4b}{a}\left[x \cdot \frac{1}{2}(a^2 - x^2)^{-1/2}(-2x) + (a^2 - x^2)^{1/2} \cdot 1\right]$
 $= \frac{4b}{a}(a^2 - x^2)^{-1/2}[-x^2 + a^2 - x^2] = \frac{4b}{a\sqrt{a^2 - x^2}}[a^2 - 2x^2]$

So the critical number is $x = \frac{1}{\sqrt{2}}a$, and this clearly gives a maximum. Then $y = \frac{1}{\sqrt{2}}b$, so the maximum area is $4\left(\frac{1}{\sqrt{2}}a\right)\left(\frac{1}{\sqrt{2}}b\right) = 2ab$.

21.

The height h of the equilateral triangle with sides of length L is $\frac{\sqrt{3}}{2}L$, since $h^2 + (L/2)^2 = L^2 \Rightarrow h^2 = L^2 - \frac{1}{4}L^2 = \frac{3}{4}L^2 \Rightarrow h = \frac{\sqrt{3}}{2}L$. Using similar triangles, $\frac{\frac{\sqrt{3}}{2}L - y}{x} = \frac{\frac{\sqrt{3}}{2}L}{L/2} = \sqrt{3} \Rightarrow \sqrt{3}x = \frac{\sqrt{3}}{2}L - y \Rightarrow y = \frac{\sqrt{3}}{2}L - \sqrt{3}x \Rightarrow y = \frac{\sqrt{3}}{2}(L - 2x)$.

The area of the inscribed rectangle is $A(x) = (2x)y = \sqrt{3}x(L - 2x) = \sqrt{3}Lx - 2\sqrt{3}x^2$, where $0 \leq x \leq L/2$. Now $0 = A'(x) = \sqrt{3}L - 4\sqrt{3}x \Rightarrow x = \sqrt{3}L/(4\sqrt{3}) = L/4$. Since $A(0) = A(L/2) = 0$, the maximum occurs when $x = L/4$, and $y = \frac{\sqrt{3}}{2}L - \frac{\sqrt{3}}{4}L = \frac{\sqrt{3}}{4}L$, so the dimensions are $L/2$ and $\frac{\sqrt{3}}{4}L$.

27.

The cylinder has surface area

 $2(\text{area of the base}) + (\text{lateral surface area})$

$$= 2\pi(\text{radius})^2 + 2\pi(\text{radius})(\text{height}) = 2\pi y^2 + 2\pi y(2x).$$

Now $x^2 + y^2 = r^2 \Rightarrow y^2 = r^2 - x^2 \Rightarrow y = \sqrt{r^2 - x^2}$, so the surface area is

$$\begin{aligned} S(x) &= 2\pi(r^2 - x^2) + 4\pi x \sqrt{r^2 - x^2}, \quad 0 \leq x \leq r \\ &= 2\pi r^2 - 2\pi x^2 + 4\pi(x \sqrt{r^2 - x^2}) \end{aligned}$$

$$\text{Thus, } S'(x) = 0 - 4\pi x + 4\pi \left[x \cdot \frac{1}{2}(r^2 - x^2)^{-1/2}(-2x) + (r^2 - x^2)^{1/2} \cdot 1 \right]$$

$$= 4\pi \left[-x - \frac{x^2}{\sqrt{r^2 - x^2}} + \sqrt{r^2 - x^2} \right] = 4\pi \cdot \frac{-x \sqrt{r^2 - x^2} - x^2 + r^2 - x^2}{\sqrt{r^2 - x^2}}$$

$$S'(x) = 0 \Rightarrow x \sqrt{r^2 - x^2} = r^2 - 2x^2 \quad (*) \Rightarrow (x \sqrt{r^2 - x^2})^2 = (r^2 - 2x^2)^2 \Rightarrow$$

$$x^2(r^2 - x^2) = r^4 - 4r^2x^2 + 4x^4 \Rightarrow r^2x^2 - x^4 = r^4 - 4r^2x^2 + 4x^4 \Rightarrow 5x^4 - 5r^2x^2 + r^4 = 0.$$

This is a quadratic equation in x^2 . By the quadratic formula, $x^2 = \frac{5 \pm \sqrt{5}}{10} r^2$, but we reject the root with the + sign since it doesn't satisfy (*). [The right side is negative and the left side is positive.] So $x = \sqrt{\frac{5 - \sqrt{5}}{10}} r$. Since

$S(0) = S(r) = 0$, the maximum surface area occurs at the critical number and $x^2 = \frac{5 - \sqrt{5}}{10} r^2 \Rightarrow$

$$y^2 = r^2 - \frac{5 - \sqrt{5}}{10} r^2 = \frac{5 + \sqrt{5}}{10} r^2 \Rightarrow \text{the surface area is}$$

$$\begin{aligned} 2\pi \left(\frac{5 + \sqrt{5}}{10} r^2 \right) + 4\pi \sqrt{\frac{5 - \sqrt{5}}{10}} \sqrt{\frac{5 + \sqrt{5}}{10}} r^2 &= \pi r^2 \left[2 \cdot \frac{5 + \sqrt{5}}{10} + 4 \frac{\sqrt{(5 - \sqrt{5})(5 + \sqrt{5})}}{10} \right] = \pi r^2 \left[\frac{5 + \sqrt{5}}{5} + \frac{2\sqrt{20}}{5} \right] = \\ \pi r^2 \left[\frac{5 + \sqrt{5} + 2 \cdot 2\sqrt{5}}{5} \right] &= \pi r^2 \left[\frac{5 + 5\sqrt{5}}{5} \right] = \pi r^2 (1 + \sqrt{5}). \end{aligned}$$

28.

$$\text{Perimeter} = 30 \Rightarrow 2y + x + \pi \left(\frac{x}{2} \right) = 30 \Rightarrow$$

$$y = \frac{1}{2} \left(30 - x - \frac{\pi x}{2} \right) = 15 - \frac{x}{2} - \frac{\pi x}{4}. \text{ The area is the area of the}$$

rectangle plus the area of the semicircle, or $xy + \frac{1}{2}\pi \left(\frac{x}{2} \right)^2$, so

$$A(x) = x \left(15 - \frac{x}{2} - \frac{\pi x}{4} \right) + \frac{1}{8}\pi x^2 = 15x - \frac{1}{2}x^2 - \frac{\pi}{8}x^2.$$

$$A'(x) = 15 - \left(1 + \frac{\pi}{4} \right)x = 0 \Rightarrow x = \frac{15}{1 + \pi/4} = \frac{60}{4 + \pi}. \quad A''(x) = - \left(1 + \frac{\pi}{4} \right) < 0, \text{ so this gives a}$$

$$\text{maximum. The dimensions are } x = \frac{60}{4 + \pi} \text{ ft and } y = 15 - \frac{30}{4 + \pi} - \frac{15\pi}{4 + \pi} = \frac{60 + 15\pi - 30 - 15\pi}{4 + \pi} = \frac{30}{4 + \pi} \text{ ft,}$$

so the height of the rectangle is half the base.

29.

$$xy = 384 \Rightarrow y = 384/x. \text{ Total area is}$$

$$A(x) = (8 + x)(12 + 384/x) = 12(40 + x + 256/x), \text{ so}$$

$$A'(x) = 12(1 - 256/x^2) = 0 \Rightarrow x = 16. \text{ There is an absolute}$$

minimum when $x = 16$ since $A'(x) < 0$ for $0 < x < 16$ and $A'(x) > 0$ for $x > 16$. When $x = 16$, $y = 384/16 = 24$, so the dimensions are 24 cm and 36 cm.

30.

$xy = 180$, so $y = 180/x$. The printed area is

$$(x-2)(y-3) = (x-2)(180/x-3) = 186 - 3x - 360/x = A(x).$$

$$A'(x) = -3 + 360/x^2 = 0 \text{ when } x^2 = 120 \Rightarrow x = 2\sqrt{30}.$$

This gives an absolute maximum since $A'(x) > 0$ for $0 < x < 2\sqrt{30}$ and

$A'(x) < 0$ for $x > 2\sqrt{30}$. When $x = 2\sqrt{30}$, $y = 180/(2\sqrt{30})$, so the dimensions are $2\sqrt{30}$ in. and $90/\sqrt{30}$ in.

31.

Let x be the length of the wire used for the square. The total area is

$$A(x) = \left(\frac{x}{4}\right)^2 + \frac{1}{2} \left(\frac{10-x}{3}\right) \frac{\sqrt{3}}{2} \left(\frac{10-x}{3}\right) \\ = \frac{1}{16}x^2 + \frac{\sqrt{3}}{36}(10-x)^2, \quad 0 \leq x \leq 10$$

$$A'(x) = \frac{1}{8}x - \frac{\sqrt{3}}{18}(10-x) = 0 \Leftrightarrow \frac{9}{72}x + \frac{4\sqrt{3}}{72}x - \frac{40\sqrt{3}}{72} = 0 \Leftrightarrow x = \frac{40\sqrt{3}}{9+4\sqrt{3}}.$$

$$A(0) = \left(\frac{\sqrt{3}}{36}\right)100 \approx 4.81, A(10) = \frac{100}{16} = 6.25 \text{ and } A\left(\frac{40\sqrt{3}}{9+4\sqrt{3}}\right) \approx 2.72, \text{ so}$$

(a) The maximum area occurs when $x = 10$ m, and all the wire is used for the square.

(b) The minimum area occurs when $x = \frac{40\sqrt{3}}{9+4\sqrt{3}} \approx 4.35$ m.

32.

$$\text{Total area is } A(x) = \left(\frac{x}{4}\right)^2 + \pi \left(\frac{10-x}{2\pi}\right)^2 = \frac{x^2}{16} + \frac{(10-x)^2}{4\pi},$$

$$0 \leq x \leq 10. \quad A'(x) = \frac{x}{8} - \frac{10-x}{2\pi} = \left(\frac{1}{2\pi} + \frac{1}{8}\right)x - \frac{5}{\pi} = 0 \Rightarrow$$

$$x = 40/(4+\pi). \quad A(0) = 25/\pi \approx 7.96, A(10) = 6.25, \text{ and}$$

$A(40/(4+\pi)) \approx 3.5$, so the maximum occurs when $x = 0$ m and the minimum occurs when $x = 40/(4+\pi)$ m.

33.

The volume is $V = \pi r^2 h$ and the surface area is

$$S(r) = \pi r^2 + 2\pi r h = \pi r^2 + 2\pi r \left(\frac{V}{\pi r^2}\right) = \pi r^2 + \frac{2V}{r}.$$

$$S'(r) = 2\pi r - \frac{2V}{r^2} = 0 \Rightarrow 2\pi r^3 = 2V \Rightarrow r = \sqrt[3]{\frac{V}{\pi}} \text{ cm.}$$

This gives an absolute minimum since $S'(r) < 0$ for $0 < r < \sqrt[3]{\frac{V}{\pi}}$ and $S'(r) > 0$ for $r > \sqrt[3]{\frac{V}{\pi}}$. When

$$r = \sqrt[3]{\frac{V}{\pi}}, h = \frac{V}{\pi r^2} = \frac{V}{\pi(V/\pi)^{2/3}} = \sqrt[3]{\frac{V}{\pi}} \text{ cm.}$$

34.

$$L = 8 \csc \theta + 4 \sec \theta, 0 < \theta < \frac{\pi}{2},$$

$$\frac{dL}{d\theta} = -8 \csc \theta \cot \theta + 4 \sec \theta \tan \theta = 0 \text{ when}$$

$$\sec \theta \tan \theta = 2 \csc \theta \cot \theta \Leftrightarrow \tan^3 \theta = 2 \Leftrightarrow \tan \theta = \sqrt[3]{2} \Leftrightarrow \theta = \tan^{-1} \sqrt[3]{2}.$$

$dL/d\theta < 0$ when $0 < \theta < \tan^{-1} \sqrt[3]{2}$, $dL/d\theta > 0$ when $\tan^{-1} \sqrt[3]{2} < \theta < \frac{\pi}{2}$, so L has an absolute minimum when

$\theta = \tan^{-1} \sqrt[3]{2}$, and the shortest ladder has length

$$L = 8 \frac{\sqrt{1 + 2^{2/3}}}{2^{1/3}} + 4 \sqrt{1 + 2^{2/3}} \approx 16.65 \text{ ft.}$$

Another method: Minimize $L^2 = x^2 + (4 + y)^2$, where $\frac{x}{4 + y} = \frac{8}{y}$.

35.

$$h^2 + r^2 = R^2 \Rightarrow V = \frac{\pi}{3} r^2 h = \frac{\pi}{3} (R^2 - h^2) h = \frac{\pi}{3} (R^2 h - h^3).$$

$V'(h) = \frac{\pi}{3} (R^2 - 3h^2) = 0$ when $h = \frac{1}{\sqrt{3}} R$. This gives an absolute maximum, since $V'(h) > 0$ for $0 < h < \frac{1}{\sqrt{3}} R$ and $V'(h) < 0$ for $h > \frac{1}{\sqrt{3}} R$. The maximum volume is

$$V\left(\frac{1}{\sqrt{3}} R\right) = \frac{\pi}{3} \left(\frac{1}{\sqrt{3}} R^3 - \frac{1}{3\sqrt{3}} R^3 \right) = \frac{2}{9\sqrt{3}} \pi R^3.$$

36. The volume and surface area of a cone with radius r and height h are given by $V = \frac{1}{3} \pi r^2 h$ and $S = \pi r \sqrt{r^2 + h^2}$.

We'll minimize $A = S^2$ subject to $V = 27$. $V = 27 \Rightarrow \frac{1}{3} \pi r^2 h = 27 \Rightarrow r^2 = \frac{81}{\pi h}$ (1).

$$A = \pi^2 r^2 (r^2 + h^2) = \pi^2 \left(\frac{81}{\pi h} \right) \left(\frac{81}{\pi h} + h^2 \right) = \frac{81^2}{h^2} + 81\pi h, \text{ so } A' = 0 \Rightarrow \frac{-2 \cdot 81^2}{h^3} + 81\pi = 0 \Rightarrow$$

$$81\pi = \frac{2 \cdot 81^2}{h^3} \Rightarrow h^3 = \frac{162}{\pi} \Rightarrow h = \sqrt[3]{\frac{162}{\pi}} = 3 \sqrt[3]{\frac{6}{\pi}} \approx 3.722. \text{ From (1),}$$

$$r^2 = \frac{81}{\pi h} = \frac{81}{\pi \cdot 3 \sqrt[3]{6/\pi}} = \frac{27}{\sqrt[3]{6\pi^2}} \Rightarrow r = \frac{3 \sqrt[3]{3}}{\sqrt[3]{6\pi^2}} \approx 2.632. A'' = 6 \cdot 81^2 / h^4 > 0, \text{ so } A \text{ and hence } S \text{ has an}$$

absolute minimum at these values of r and h .

37.

By similar triangles, $\frac{H}{R} = \frac{H-h}{r}$ (1). The volume of the inner cone is

$$V = \frac{1}{3} \pi r^2 h, \text{ so we'll solve (1) for } h. \frac{Hr}{R} = H - h \Rightarrow$$

$$h = H - \frac{Hr}{R} = \frac{HR - Hr}{R} = \frac{H}{R} (R - r) \quad (2).$$

$$\text{Thus, } V(r) = \frac{\pi}{3} r^2 \cdot \frac{H}{R} (R - r) = \frac{\pi H}{3R} (Rr^2 - r^3) \Rightarrow$$

$$V'(r) = \frac{\pi H}{3R} (2Rr - 3r^2) = \frac{\pi H}{3R} r (2R - 3r).$$

$$V'(r) = 0 \Rightarrow r = 0 \text{ or } 2R = 3r \Rightarrow r = \frac{2}{3}R \text{ and from (2), } h = \frac{H}{R}\left(R - \frac{2}{3}R\right) = \frac{H}{R}\left(\frac{1}{3}R\right) = \frac{1}{3}H.$$

$V'(r)$ changes from positive to negative at $r = \frac{2}{3}R$, so the inner cone has a maximum volume of

$$V = \frac{1}{3}\pi r^2 h = \frac{1}{3}\pi\left(\frac{2}{3}R\right)^2\left(\frac{1}{3}H\right) = \frac{4}{27} \cdot \frac{1}{3}\pi R^2 H, \text{ which is approximately 15\% of the volume of the larger cone.}$$

$$38. (a) E(v) = \frac{aLv^3}{v-u} \Rightarrow E'(v) = aL \frac{(v-u)3v^2 - v^3}{(v-u)^2} = 0$$

$$\text{when } 2v^3 = 3uv^2 \Rightarrow 2v = 3u \Rightarrow v = \frac{3}{2}u.$$

The First Derivative Test shows that this value of v gives the minimum value of E .

$$39. S = 6sh - \frac{3}{2}s^2 \cot \theta + 3s^2 \frac{\sqrt{3}}{2} \csc \theta$$

$$(a) \frac{dS}{d\theta} = \frac{3}{2}s^2 \csc^2 \theta - 3s^2 \frac{\sqrt{3}}{2} \csc \theta \cot \theta \text{ or } \frac{3}{2}s^2 \csc \theta (\csc \theta - \sqrt{3} \cot \theta).$$

$$(b) \frac{dS}{d\theta} = 0 \text{ when } \csc \theta - \sqrt{3} \cot \theta = 0 \Rightarrow \frac{1}{\sin \theta} - \sqrt{3} \frac{\cos \theta}{\sin \theta} = 0 \Rightarrow \cos \theta = \frac{1}{\sqrt{3}}. \text{ The First Derivative Test shows that the minimum surface area occurs when } \theta = \cos^{-1}\left(\frac{1}{\sqrt{3}}\right) \approx 55^\circ.$$

If $\cos \theta = \frac{1}{\sqrt{3}}$, then $\cot \theta = \frac{1}{\sqrt{2}}$ and $\csc \theta = \frac{\sqrt{3}}{\sqrt{2}}$, so the surface area is

$$\begin{aligned} S &= 6sh - \frac{3}{2}s^2 \frac{1}{\sqrt{2}} + 3s^2 \frac{\sqrt{3}}{2} \frac{\sqrt{3}}{\sqrt{2}} = 6sh - \frac{3}{2\sqrt{2}}s^2 + \frac{9}{2\sqrt{2}}s^2 \\ &= 6sh + \frac{6}{2\sqrt{2}}s^2 = 6s\left(h + \frac{1}{\sqrt{2}}s\right) \end{aligned}$$

Let t be the time, in hours, after 2:00 P.M. The position of the boat heading south at time t is $(0, -20t)$. The position of the boat heading east at time t is $(-15 + 15t, 0)$. If $D(t)$ is the distance between the boats at time t , we minimize $f(t) = [D(t)]^2 = 20^2 t^2 + 15^2 (t-1)^2$.

$$f'(t) = 800t + 450(t-1) = 1250t - 450 = 0 \text{ when } t = \frac{450}{1250} = 0.36 \text{ h.}$$

$0.36 \text{ h} \times \frac{60 \text{ min}}{\text{h}} = 21.6 \text{ min} = 21 \text{ min } 36 \text{ s.}$ Since $f''(t) > 0$, this gives a minimum, so the boats are closest together at 2:21:36 P.M.

$$41. \text{ Here } T(x) = \frac{\sqrt{x^2 + 25}}{6} + \frac{5-x}{8}, 0 \leq x \leq 5 \Rightarrow T'(x) = \frac{x}{6\sqrt{x^2 + 25}} - \frac{1}{8} = 0 \Leftrightarrow 8x = 6\sqrt{x^2 + 25}$$

$$\Leftrightarrow 16x^2 = 9(x^2 + 25) \Leftrightarrow x = \frac{15}{\sqrt{7}}. \text{ But } \frac{15}{\sqrt{7}} > 5, \text{ so } T \text{ has no critical number. Since } T(0) \approx 1.46 \text{ and}$$

$T(5) \approx 1.18$, he should row directly to B .

42.

In isosceles triangle AOB , $\angle O = 180^\circ - \theta - \theta$, so $\angle BOC = 2\theta$. The distance rowed is $4 \cos \theta$ while the distance walked is the length of arc $BC = 2(2\theta) = 4\theta$. The time taken is given by

$$T(\theta) = \frac{4 \cos \theta}{2} + \frac{4\theta}{4} = 2 \cos \theta + \theta, \quad 0 \leq \theta \leq \frac{\pi}{2}.$$

$$T'(\theta) = -2 \sin \theta + 1 = 0 \Leftrightarrow \sin \theta = \frac{1}{2} \Rightarrow \theta = \frac{\pi}{6}.$$

Check the value of T at $\theta = \frac{\pi}{6}$ and at the endpoints of the domain of T ; that is, $\theta = 0$ and $\theta = \frac{\pi}{2}$. $T(0) = 2$,

$T(\frac{\pi}{6}) = \sqrt{3} + \frac{\pi}{6} \approx 2.26$, and $T(\frac{\pi}{2}) = \frac{\pi}{2} \approx 1.57$. Therefore, the minimum value of T is $\frac{\pi}{2}$ when $\theta = \frac{\pi}{2}$; that is, the woman should walk all the way. Note that $T''(\theta) = -2 \cos \theta < 0$ for $0 \leq \theta < \frac{\pi}{2}$, so $\theta = \frac{\pi}{6}$ gives a maximum time.

43.

The total illumination is $I(x) = \frac{3k}{x^2} + \frac{k}{(10-x)^2}$, $0 < x < 10$. Then

$$I'(x) = \frac{-6k}{x^3} + \frac{2k}{(10-x)^3} = 0 \Rightarrow 6k(10-x)^3 = 2kx^3 \Rightarrow$$

$$3(10-x)^3 = x^3 \Rightarrow \sqrt[3]{3}(10-x) = x \Rightarrow 10\sqrt[3]{3} - \sqrt[3]{3}x = x$$

$$\Rightarrow 10\sqrt[3]{3} = x + \sqrt[3]{3}x \Rightarrow 10\sqrt[3]{3} = (1 + \sqrt[3]{3})x \Rightarrow$$

$$x = \frac{10\sqrt[3]{3}}{1 + \sqrt[3]{3}} \approx 5.9 \text{ ft. This gives a minimum since } I''(x) > 0 \text{ for}$$

$$0 < x < 10.$$

44.

The line with slope m (where $m < 0$) through $(3, 5)$ has equation $y - 5 = m(x - 3)$ or $y = mx + (5 - 3m)$. The y -intercept is $5 - 3m$ and the x -intercept is $-5/m + 3$.

So the triangle has area $A(m) = \frac{1}{2}(5 - 3m)(-5/m + 3) = 15 - 25/(2m) - \frac{9}{2}m$.

$$\text{Now } A'(m) = \frac{25}{2m^2} - \frac{9}{2} = 0 \Leftrightarrow m^2 = \frac{25}{9} \Rightarrow m = -\frac{5}{3} \text{ (since } m < 0).$$

$$A''(m) = -\frac{25}{m^3} > 0, \text{ so there is an absolute minimum when } m = -\frac{5}{3}. \text{ Thus, an}$$

$$\text{equation of the line is } y - 5 = -\frac{5}{3}(x - 3) \text{ or } y = -\frac{5}{3}x + 10.$$

45.

Every line segment in the first quadrant passing through (a, b) with endpoints on the x - and y -axes satisfies an equation of the form $y - b = m(x - a)$, where $m < 0$. By setting $x = 0$ and then $y = 0$, we find its endpoints, $A(0, b - am)$ and $B(a - \frac{b}{m}, 0)$.

$$\text{The distance } d \text{ from } A \text{ to } B \text{ is given by } d = \sqrt{[(a - \frac{b}{m}) - 0]^2 + [0 - (b - am)]^2}.$$

It follows that the square of the length of the line segment, as a function of m , is given by

$$S(m) = \left(a - \frac{b}{m}\right)^2 + (am - b)^2 = a^2 - \frac{2ab}{m} + \frac{b^2}{m^2} + a^2m^2 - 2abm + b^2. \text{ Thus,}$$

$$\begin{aligned} S'(m) &= \frac{2ab}{m^2} - \frac{2b^2}{m^3} + 2a^2m - 2ab = \frac{2}{m^3}(abm - b^2 + a^2m^4 - abm^3) \\ &= \frac{2}{m^3}[b(am - b) + am^3(am - b)] = \frac{2}{m^3}(am - b)(b + am^3) \end{aligned}$$

Thus, $S'(m) = 0 \Leftrightarrow m = b/a$ or $m = -\sqrt[3]{\frac{b}{a}}$. Since $b/a > 0$ and $m < 0$, m must equal $-\sqrt[3]{\frac{b}{a}}$. Since

$\frac{2}{m^3} < 0$, we see that $S'(m) < 0$ for $m < -\sqrt[3]{\frac{b}{a}}$ and $S'(m) > 0$ for $m > -\sqrt[3]{\frac{b}{a}}$. Thus, S has its absolute

minimum value when $m = -\sqrt[3]{\frac{b}{a}}$. That value is

$$\begin{aligned} S\left(-\sqrt[3]{\frac{b}{a}}\right) &= \left(a + b\sqrt[3]{\frac{a}{b}}\right)^2 + \left(-a\sqrt[3]{\frac{b}{a}} - b\right)^2 = \left(a + \sqrt[3]{ab^2}\right)^2 + \left(\sqrt[3]{a^2b} + b\right)^2 \\ &= a^2 + 2a^{4/3}b^{2/3} + a^{2/3}b^{4/3} + a^{4/3}b^{2/3} + 2a^{2/3}b^{4/3} + b^2 = a^2 + 3a^{4/3}b^{2/3} + 3a^{2/3}b^{4/3} + b^2 \end{aligned}$$

The last expression is of the form $x^3 + 3x^2y + 3xy^2 + y^3 = (x + y)^3$ with $x = a^{2/3}$ and $y = b^{2/3}$,

so we can write it as $(a^{2/3} + b^{2/3})^3$ and the shortest such line segment has length $\sqrt{S} = (a^{2/3} + b^{2/3})^{3/2}$.

46. $y = 1 + 40x^3 - 3x^5 \Rightarrow y' = 120x^2 - 15x^4$, so the tangent line to the curve at $x = a$ has slope

$$m(a) = 120a^2 - 15a^4. \text{ Now } m'(a) = 240a - 60a^3 = -60a(a^2 - 4) = -60a(a + 2)(a - 2), \text{ so } m'(a) > 0$$

for $a < -2$, and $0 < a < 2$, and $m'(a) < 0$ for $-2 < a < 0$ and $a > 2$. Thus, m is increasing on $(-\infty, -2)$,

decreasing on $(-2, 0)$, increasing on $(0, 2)$, and decreasing on $(2, \infty)$. Clearly, $m(a) \rightarrow -\infty$ as $a \rightarrow \pm\infty$, so the

maximum value of $m(a)$ must be one of the two local maxima, $m(-2)$ or $m(2)$. But both $m(-2)$ and $m(2)$ equal

$$120 \cdot 2^2 - 15 \cdot 2^4 = 480 - 240 = 240. \text{ So } 240 \text{ is the largest slope, and it occurs at the points } (-2, -223) \text{ and}$$

$(2, 225)$. Note: $a = 0$ corresponds to a local minimum of m .

47.

$$\text{Here } s^2 = h^2 + b^2/4, \text{ so } h^2 = s^2 - b^2/4. \text{ The area is } A = \frac{1}{2}b\sqrt{s^2 - b^2/4}.$$

$$\text{Let the perimeter be } p, \text{ so } 2s + b = p \text{ or } s = (p - b)/2 \Rightarrow$$

$$A(b) = \frac{1}{2}b\sqrt{(p - b)^2/4 - b^2/4} = b\sqrt{p^2 - 2pb}/4. \text{ Now}$$

$$A'(b) = \frac{\sqrt{p^2 - 2pb}}{4} - \frac{bp/4}{\sqrt{p^2 - 2pb}} = \frac{-3pb + p^2}{4\sqrt{p^2 - 2pb}}. \text{ Therefore, } A'(b) = 0 \Rightarrow$$

$$-3pb + p^2 = 0 \Rightarrow b = p/3. \text{ Since } A'(b) > 0 \text{ for } b < p/3 \text{ and } A'(b) < 0 \text{ for } b > p/3, \text{ there is an absolute}$$

maximum when $b = p/3$. But then $2s + p/3 = p$, so $s = p/3 \Rightarrow s = b \Rightarrow$ the triangle is equilateral.

48. See the figure. The area is given by

$$A(x) = \frac{1}{2}(2\sqrt{a^2 - x^2})x + \frac{1}{2}(2\sqrt{a^2 - x^2})(\sqrt{x^2 + b^2 - a^2}) = \sqrt{a^2 - x^2}(x + \sqrt{x^2 + b^2 - a^2}) \text{ for}$$

$$0 \leq x \leq a. \text{ Now } A'(x) = \sqrt{a^2 - x^2} \left(1 + \frac{x}{\sqrt{x^2 + b^2 - a^2}} \right) + (x + \sqrt{x^2 + b^2 - a^2}) \frac{-x}{\sqrt{a^2 - x^2}} = 0 \Leftrightarrow$$

$$\frac{x}{\sqrt{a^2 - x^2}}(x + \sqrt{x^2 + b^2 - a^2}) = \sqrt{a^2 - x^2} \left(\frac{x + \sqrt{x^2 + b^2 - a^2}}{\sqrt{x^2 + b^2 - a^2}} \right).$$

Except for the trivial case where $x = 0$, $a = b$ and $A(x) = 0$, we have

$x + \sqrt{x^2 + b^2 - a^2} > 0$. Hence, cancelling this factor gives

$$\begin{aligned} \frac{x}{\sqrt{a^2 - x^2}} &= \frac{\sqrt{a^2 - x^2}}{\sqrt{x^2 + b^2 - a^2}} \Rightarrow x\sqrt{x^2 + b^2 - a^2} = a^2 - x^2 \Rightarrow \\ x^2(x^2 + b^2 - a^2) &= a^4 - 2a^2x^2 + x^4 \Rightarrow x^2(b^2 - a^2) = a^4 - 2a^2x^2 \\ \Rightarrow x^2(b^2 + a^2) &= a^4 \Rightarrow x = \frac{a^2}{\sqrt{a^2 + b^2}}. \end{aligned}$$

Now we must check the value of A at this point as well as at the endpoints of the domain to see which gives the maximum value. $A(0) = a\sqrt{b^2 - a^2}$, $A(a) = 0$ and

$$\begin{aligned} A\left(\frac{a^2}{\sqrt{a^2 + b^2}}\right) &= \sqrt{a^2 - \left(\frac{a^2}{\sqrt{a^2 + b^2}}\right)^2} \left[\frac{a^2}{\sqrt{a^2 + b^2}} + \sqrt{\left(\frac{a^2}{\sqrt{a^2 + b^2}}\right)^2 + b^2 - a^2} \right] \\ &= \frac{ab}{\sqrt{a^2 + b^2}} \left[\frac{a^2}{\sqrt{a^2 + b^2}} + \frac{b^2}{\sqrt{a^2 + b^2}} \right] = \frac{ab(a^2 + b^2)}{a^2 + b^2} = ab \end{aligned}$$

Since $b \geq \sqrt{b^2 - a^2}$, $A(a^2/\sqrt{a^2 + b^2}) \geq A(0)$. So there is an absolute maximum when $x = \frac{a^2}{\sqrt{a^2 + b^2}}$. In this

case the horizontal piece should be $\frac{2ab}{\sqrt{a^2 + b^2}}$ and the vertical piece should be $\frac{a^2 + b^2}{\sqrt{a^2 + b^2}} = \sqrt{a^2 + b^2}$.

49. Note that $|AD| = |AP| + |PD| \Rightarrow 5 = x + |PD| \Rightarrow |PD| = 5 - x$. Using the Pythagorean Theorem for $\triangle PDB$ and $\triangle PDC$ gives us

$$\begin{aligned} L(x) &= |AP| + |BP| + |CP| = x + \sqrt{(5-x)^2 + 2^2} + \sqrt{(5-x)^2 + 3^2} \\ &= x + \sqrt{x^2 - 10x + 29} + \sqrt{x^2 - 10x + 34} \end{aligned}$$

$$\Rightarrow L'(x) = 1 + \frac{x-5}{\sqrt{x^2 - 10x + 29}} + \frac{x-5}{\sqrt{x^2 - 10x + 34}}.$$

From the graphs of L and L' , it seems that the minimum value of L is about $L(3.59) = 9.35$ m.

50. We note that since c is the consumption in gallons per hour, and v is the velocity in miles per hour, then

$\frac{c}{v} = \frac{\text{gallons/hour}}{\text{miles/hour}} = \frac{\text{gallons}}{\text{mile}}$ gives us the consumption in gallons per mile, that is, the quantity G . To find the

minimum, we calculate $\frac{dG}{dv} = \frac{d}{dv} \left(\frac{c}{v} \right) = \frac{v \frac{dc}{dv} - c \frac{dv}{dv}}{v^2} = \frac{v \frac{dc}{dv} - c}{v^2}$.

This is 0 when $v \frac{dc}{dv} - c = 0 \Leftrightarrow \frac{dc}{dv} = \frac{c}{v}$. This implies that the tangent line of $c(v)$ passes through the origin, and this occurs when $v \approx 53$ mi/h. Note that the slope of the secant line through the origin and a point $(v, c(v))$ on the graph is equal to $G(v)$, and it is intuitively clear that G is minimized in the case where the secant is in fact a tangent.

51.

The total time is

$$T(x) = (\text{time from } A \text{ to } C) + (\text{time from } C \text{ to } B) \\ = \frac{\sqrt{a^2 + x^2}}{v_1} + \frac{\sqrt{b^2 + (d-x)^2}}{v_2}, \quad 0 < x < d$$

$$T'(x) = \frac{x}{v_1 \sqrt{a^2 + x^2}} - \frac{d-x}{v_2 \sqrt{b^2 + (d-x)^2}} = \frac{\sin \theta_1}{v_1} - \frac{\sin \theta_2}{v_2}$$

The minimum occurs when $T'(x) = 0 \Rightarrow \frac{\sin \theta_1}{v_1} = \frac{\sin \theta_2}{v_2}$.

[Note: $T''(x) > 0$]

52.

If $d = |QT|$, we minimize $f(\theta_1) = |PR| + |RS| = a \csc \theta_1 + b \csc \theta_2$.

Differentiating with respect to θ_1 , and setting $\frac{df}{d\theta_1}$ equal to 0, we get

$$\frac{df}{d\theta_1} = 0 = -a \csc \theta_1 \cot \theta_1 - b \csc \theta_2 \cot \theta_2 \frac{d\theta_2}{d\theta_1}.$$

So we need to find an expression for $\frac{d\theta_2}{d\theta_1}$. We can do this by observing that $|QT| = \text{constant} = a \cot \theta_1 + b \cot \theta_2$.

Differentiating this equation implicitly with respect to θ_1 , we get $-a \csc^2 \theta_1 - b \csc^2 \theta_2 \frac{d\theta_2}{d\theta_1} = 0 \Rightarrow$

$\frac{d\theta_2}{d\theta_1} = -\frac{a \csc^2 \theta_1}{b \csc^2 \theta_2}$. We substitute this into the expression for $\frac{df}{d\theta_1}$ to get

$$-a \csc \theta_1 \cot \theta_1 - b \csc \theta_2 \cot \theta_2 \left(-\frac{a \csc^2 \theta_1}{b \csc^2 \theta_2} \right) = 0 \Leftrightarrow -a \csc \theta_1 \cot \theta_1 + a \frac{\csc^2 \theta_1 \cot \theta_2}{\csc \theta_2} = 0 \Leftrightarrow$$

$\cot \theta_1 \csc \theta_2 = \csc \theta_1 \cot \theta_2 \Leftrightarrow \frac{\cot \theta_1}{\csc \theta_1} = \frac{\cot \theta_2}{\csc \theta_2} \Leftrightarrow \cos \theta_1 = \cos \theta_2$. Since θ_1 and θ_2 are both acute, we have $\theta_1 = \theta_2$.

53.

$y^2 = x^2 + z^2$, but triangles CDE and BCA are similar, so

$$z/8 = x/(4\sqrt{x-4}) \Rightarrow z = 2x/\sqrt{x-4}. \text{ Thus, we minimize}$$

$$f(x) = y^2 = x^2 + 4x^2/(x-4) = x^3/(x-4), \quad 4 < x \leq 8.$$

$$f'(x) = \frac{(x-4)(3x^2) - x^3}{(x-4)^2} = \frac{x^2[3(x-4) - x]}{(x-4)^2} = \frac{2x^2(x-6)}{(x-4)^2} = 0$$

when $x = 6$. $f'(x) < 0$ when $x < 6$, $f'(x) > 0$ when $x > 6$, so the minimum occurs when $x = 6$ in.

54.

Paradoxically, we solve this maximum problem by solving a minimum problem. Let L be the length of the line ACB going from wall to wall touching the inner corner C . As $\theta \rightarrow 0$ or $\theta \rightarrow \frac{\pi}{2}$, we have $L \rightarrow \infty$ and there will be an angle that makes L a minimum. A pipe of this length will just fit around the corner.

$$\text{From the diagram, } L = L_1 + L_2 = 9 \csc \theta + 6 \sec \theta \Rightarrow dL/d\theta = -9 \csc \theta \cot \theta + 6 \sec \theta \tan \theta = 0 \text{ when}$$

$$6 \sec \theta \tan \theta = 9 \csc \theta \cot \theta \Leftrightarrow \tan^3 \theta = \frac{9}{6} = 1.5 \Leftrightarrow \tan \theta = \sqrt[3]{1.5}. \text{ Then } \sec^2 \theta = 1 + \left(\frac{3}{2}\right)^{2/3} \text{ and}$$

$$\csc^2 \theta = 1 + \left(\frac{3}{2}\right)^{-2/3}, \text{ so the longest pipe has length } L = 9 \left[1 + \left(\frac{3}{2}\right)^{-2/3}\right]^{1/2} + 6 \left[1 + \left(\frac{3}{2}\right)^{2/3}\right]^{1/2} \approx 21.07 \text{ ft.}$$

$$\text{Or, use } \theta = \tan^{-1}(\sqrt[3]{1.5}) \approx 0.852 \Rightarrow L = 9 \csc \theta + 6 \sec \theta \approx 21.07 \text{ ft.}$$

55.

It suffices to maximize $\tan \theta$. Now

$$\frac{3t}{1} = \tan(\psi + \theta) = \frac{\tan \psi + \tan \theta}{1 - \tan \psi \tan \theta} = \frac{t + \tan \theta}{1 - t \tan \theta}.$$

$$\text{So } 3t(1 - t \tan \theta) = t + \tan \theta \Rightarrow 2t = (1 + 3t^2) \tan \theta \Rightarrow$$

$$\tan \theta = \frac{2t}{1 + 3t^2}. \text{ Let } f(t) = \tan \theta = \frac{2t}{1 + 3t^2} \Rightarrow$$

$$f'(t) = \frac{2(1 + 3t^2) - 2t(6t)}{(1 + 3t^2)^2} = \frac{2(1 - 3t^2)}{(1 + 3t^2)^2} = 0 \Leftrightarrow$$

$$1 - 3t^2 = 0 \Leftrightarrow t = \frac{1}{\sqrt{3}} \text{ since } t \geq 0.$$

Now $f'(t) > 0$ for $0 \leq t < \frac{1}{\sqrt{3}}$ and $f'(t) < 0$ for $t > \frac{1}{\sqrt{3}}$, so f has an absolute maximum when $t = \frac{1}{\sqrt{3}}$

$$\text{and } \tan \theta = \frac{2(1/\sqrt{3})}{1 + 3(1/\sqrt{3})^2} = \frac{1}{\sqrt{3}} \Rightarrow \theta = \frac{\pi}{6}. \text{ Substituting for } t \text{ and } \theta \text{ in } 3t = \tan(\psi + \theta) \text{ gives us}$$

$$\sqrt{3} = \tan\left(\psi + \frac{\pi}{6}\right) \Rightarrow \psi = \frac{\pi}{6}.$$

56.

We maximize the cross-sectional area

$$\begin{aligned}
 A(\theta) &= 10h + 2\left(\frac{1}{2}dh\right) = 10h + dh = 10(10\sin\theta) + (10\cos\theta)(10\sin\theta) \\
 &= 100(\sin\theta + \sin\theta\cos\theta), \quad 0 \leq \theta \leq \frac{\pi}{2} \\
 A'(\theta) &= 100(\cos\theta + \cos^2\theta - \sin^2\theta) = 100(\cos\theta + 2\cos^2\theta - 1) = 100(2\cos\theta - 1)(\cos\theta + 1) \\
 &= 0 \text{ when } \cos\theta = \frac{1}{2} \Leftrightarrow \theta = \frac{\pi}{3}. \quad (\cos\theta \neq -1 \text{ since } 0 \leq \theta \leq \frac{\pi}{2}.)
 \end{aligned}$$

Now $A(0) = 0$, $A(\frac{\pi}{2}) = 100$ and $A(\frac{\pi}{3}) = 75\sqrt{3} \approx 129.9$, so the maximum occurs when $\theta = \frac{\pi}{3}$.

57.

From the figure, $\tan\alpha = \frac{5}{x}$ and $\tan\beta = \frac{2}{3-x}$. Since

$$\alpha + \beta + \theta = 180^\circ = \pi, \quad \theta = \pi - \tan^{-1}\left(\frac{5}{x}\right) - \tan^{-1}\left(\frac{2}{3-x}\right) \Rightarrow$$

$$\begin{aligned}
 \frac{d\theta}{dx} &= -\frac{1}{1 + \left(\frac{5}{x}\right)^2} \left(-\frac{5}{x^2}\right) - \frac{1}{1 + \left(\frac{2}{3-x}\right)^2} \left[\frac{2}{(3-x)^2}\right] \\
 &= \frac{x^2}{x^2 + 25} \cdot \frac{5}{x^2} - \frac{(3-x)^2}{(3-x)^2 + 4} \cdot \frac{2}{(3-x)^2}.
 \end{aligned}$$

$$\text{Now } \frac{d\theta}{dx} = 0 \Rightarrow \frac{5}{x^2 + 25} = \frac{2}{x^2 - 6x + 13} \Rightarrow 2x^2 + 50 = 5x^2 - 30x + 65 \Rightarrow$$

$$3x^2 - 30x + 15 = 0 \Rightarrow x^2 - 10x + 5 = 0 \Rightarrow x = 5 \pm 2\sqrt{5}. \text{ We reject the root with the } + \text{ sign,}$$

since it is larger than 3. $d\theta/dx > 0$ for $x < 5 - 2\sqrt{5}$ and $d\theta/dx < 0$ for $x > 5 - 2\sqrt{5}$, so θ is maximized when $|AP| = x = 5 - 2\sqrt{5} \approx 0.53$.

58. Let x be the distance from the observer to the wall. Then, from the given figure,

$$\theta = \tan^{-1}\left(\frac{h+d}{x}\right) - \tan^{-1}\left(\frac{d}{x}\right), \quad x > 0 \Rightarrow$$

$$\begin{aligned}
 \frac{d\theta}{dx} &= \frac{1}{1 + [(h+d)/x]^2} \left[-\frac{h+d}{x^2}\right] - \frac{1}{1 + (d/x)^2} \left[-\frac{d}{x^2}\right] = -\frac{h+d}{x^2 + (h+d)^2} + \frac{d}{x^2 + d^2} \\
 &= \frac{d[x^2 + (h+d)^2] - (h+d)(x^2 + d^2)}{[x^2 + (h+d)^2](x^2 + d^2)} = \frac{h^2d + hd^2 - hx^2}{[x^2 + (h+d)^2](x^2 + d^2)} = 0 \Leftrightarrow
 \end{aligned}$$

$$hx^2 = h^2d + hd^2 \Leftrightarrow x^2 = hd + d^2 \Leftrightarrow x = \sqrt{d(h+d)}. \text{ Since } d\theta/dx > 0 \text{ for all } x < \sqrt{d(h+d)} \text{ and}$$

$$d\theta/dx < 0 \text{ for all } x > \sqrt{d(h+d)}, \text{ the absolute maximum occurs when } x = \sqrt{d(h+d)}.$$

59.

In the small triangle with sides a and c and hypotenuse W , $\sin \theta = \frac{a}{W}$ and $\cos \theta = \frac{c}{W}$. In the triangle with sides b and d and hypotenuse L , $\sin \theta = \frac{d}{L}$ and $\cos \theta = \frac{b}{L}$. Thus, $a = W \sin \theta$, $c = W \cos \theta$, $d = L \sin \theta$, and $b = L \cos \theta$, so the area of the circumscribed rectangle is

$$\begin{aligned} A(\theta) &= (a+b)(c+d) = (W \sin \theta + L \cos \theta)(W \cos \theta + L \sin \theta) \\ &= W^2 \sin \theta \cos \theta + WL \sin^2 \theta + LW \cos^2 \theta + L^2 \sin \theta \cos \theta \\ &= LW \sin^2 \theta + LW \cos^2 \theta + (L^2 + W^2) \sin \theta \cos \theta \\ &= LW(\sin^2 \theta + \cos^2 \theta) + (L^2 + W^2) \cdot \frac{1}{2} \cdot 2 \sin \theta \cos \theta \\ &= LW + \frac{1}{2}(L^2 + W^2) \sin 2\theta, \quad 0 \leq \theta \leq \frac{\pi}{2} \end{aligned}$$

This expression shows, without calculus, that the maximum value of $A(\theta)$ occurs when $\sin 2\theta = 1 \Leftrightarrow 2\theta = \frac{\pi}{2} \Rightarrow \theta = \frac{\pi}{4}$. So the maximum area is $A(\frac{\pi}{4}) = LW + \frac{1}{2}(L^2 + W^2) = \frac{1}{2}(L^2 + 2LW + W^2) = \frac{1}{2}(L+W)^2$.

60. (a) Let D be the point such that $a = |AD|$. From the figure, $\sin \theta = \frac{b}{|BC|} \Rightarrow |BC| = b \csc \theta$ and

$$\cos \theta = \frac{|BD|}{|BC|} = \frac{a - |AB|}{|BC|} \Rightarrow |BC| = (a - |AB|) \sec \theta. \text{ Eliminating } |BC| \text{ gives}$$

$$(a - |AB|) \sec \theta = b \csc \theta \Rightarrow b \cot \theta = a - |AB| \Rightarrow |AB| = a - b \cot \theta. \text{ The total resistance is}$$

$$R(\theta) = C \frac{|AB|}{r_1^4} + C \frac{|BC|}{r_2^4} = C \left(\frac{a - b \cot \theta}{r_1^4} + \frac{b \csc \theta}{r_2^4} \right).$$

$$(b) R'(\theta) = C \left(\frac{b \csc^2 \theta}{r_1^4} - \frac{b \csc \theta \cot \theta}{r_2^4} \right) = bC \csc \theta \left(\frac{\csc \theta}{r_1^4} - \frac{\cot \theta}{r_2^4} \right).$$

$$R'(\theta) = 0 \Leftrightarrow \frac{\csc \theta}{r_1^4} = \frac{\cot \theta}{r_2^4} \Leftrightarrow \frac{r_2^4}{r_1^4} = \frac{\cot \theta}{\csc \theta} = \cos \theta.$$

$$R'(\theta) > 0 \Leftrightarrow \frac{\csc \theta}{r_1^4} > \frac{\cot \theta}{r_2^4} \Rightarrow \cos \theta < \frac{r_2^4}{r_1^4} \text{ and } R'(\theta) < 0 \text{ when } \cos \theta > \frac{r_2^4}{r_1^4}, \text{ so there is an absolute minimum when } \cos \theta = r_2^4/r_1^4.$$

$$(c) \text{ When } r_2 = \frac{2}{3}r_1, \text{ we have } \cos \theta = \left(\frac{2}{3}\right)^4, \text{ so } \theta = \cos^{-1}\left(\frac{2}{3}\right)^4 \approx 79^\circ.$$

61. (a)

If k = energy/km over land, then

energy/km over water = $1.4k$. So the total energy is

$$E = 1.4k \sqrt{25 + x^2} + k(13 - x), \quad 0 \leq x \leq 13,$$

$$\text{and so } \frac{dE}{dx} = \frac{1.4kx}{(25 + x^2)^{1/2}} - k.$$

Set $\frac{dE}{dx} = 0$: $1.4kx = k(25 + x^2)^{1/2} \Rightarrow 1.96x^2 = x^2 + 25 \Rightarrow 0.96x^2 = 25 \Rightarrow x = \frac{5}{\sqrt{0.96}} \approx 5.1$.

Testing against the value of E at the endpoints: $E(0) = 1.4k(5) + 13k = 20k$, $E(5.1) \approx 17.9k$,

$E(13) \approx 19.5k$. Thus, to minimize energy, the bird should fly to a point about 5.1 km from B .

- (b) If W/L is large, the bird would fly to a point C that is closer to B than to D to minimize the energy used flying over water. If W/L is small, the bird would fly to a point C that is closer to D than to B to minimize the

distance of the flight. $E = W\sqrt{25 + x^2} + L(13 - x) \Rightarrow \frac{dE}{dx} = \frac{Wx}{\sqrt{25 + x^2}} - L = 0$ when

$\frac{W}{L} = \frac{\sqrt{25 + x^2}}{x}$. By the same sort of argument as in part (a), this ratio will give the minimal expenditure of energy if the bird heads for the point x km from B .

- (c) For flight direct to D , $x = 13$, so from part (b), $W/L = \frac{\sqrt{25 + 13^2}}{13} \approx 1.07$. There is no value of W/L for which the bird should fly directly to B . But note that $\lim_{x \rightarrow 0^+} (W/L) = \infty$, so if the point at which E is a minimum is close to B , then W/L is large.

- (d) Assuming that the birds instinctively choose the path that minimizes the energy expenditure, we can use the equation for $dE/dx = 0$ from part (a) with $1.4k = c$, $x = 4$, and $k = 1$: $(c)(4) = 1 \cdot (25 + 4^2)^{1/2} \Rightarrow c = \sqrt{41}/4 \approx 1.6$.

62. (a) $I(x) \propto \frac{\text{strength of source}}{(\text{distance from source})^2}$. Adding the intensities from the left and right lightbulbs,

$$I(x) = \frac{k}{x^2 + d^2} + \frac{k}{(10 - x)^2 + d^2} = \frac{k}{x^2 + d^2} + \frac{k}{x^2 - 20x + 100 + d^2}.$$

- (b) The magnitude of the constant k won't affect the location of the point of maximum intensity, so for convenience

we take $k = 1$. $I'(x) = -\frac{2x}{(x^2 + d^2)^2} - \frac{2(x - 10)}{(x^2 - 20x + 100 + d^2)^2}$.

Substituting $d = 5$ into the equations for $I(x)$ and $I'(x)$, we get

$$I_5(x) = \frac{1}{x^2 + 25} + \frac{1}{x^2 - 20x + 125} \quad \text{and} \quad I'_5(x) = -\frac{2x}{(x^2 + 25)^2} - \frac{2(x - 10)}{(x^2 - 20x + 125)^2}$$

From the graphs, it appears that $I_5(x)$ has a minimum at $x = 5$ m.

(c) Substituting $d = 10$ into the equations for $I(x)$ and $I'(x)$ gives $I_{10}(x) = \frac{1}{x^2 + 100} + \frac{1}{x^2 - 20x + 200}$ and

$$I'_{10}(x) = -\frac{2x}{(x^2 + 100)^2} - \frac{2(x - 10)}{(x^2 - 20x + 200)^2}.$$

From the graphs, it seems that for $d = 10$, the intensity is minimized at the endpoints, that is, $x = 0$ and $x = 10$. The midpoint is now the most brightly lit point!

(d) From the first figures in parts (b) and (c), we see that the minimal illumination changes from the midpoint ($x = 5$ with $d = 5$) to the endpoints ($x = 0$ and $x = 10$ with $d = 10$).

So we try $d = 6$ (see the first figure) and we see that the minimum value still occurs at $x = 5$. Next, we let $d = 8$ (see the second figure) and we see that the minimum value occurs at the endpoints. It appears that for some value of d between 6 and 8, we must have minima at both the midpoint and the endpoints, that is, $I(5)$ must equal $I(0)$. To find this value of d , we solve $I(0) = I(5)$ (with $k = 1$):

$$\frac{1}{d^2} + \frac{1}{100 + d^2} = \frac{1}{25 + d^2} + \frac{1}{25 + d^2} = \frac{2}{25 + d^2} \Rightarrow$$

$$(25 + d^2)(100 + d^2) + d^2(25 + d^2) = 2d^2(100 + d^2) \Rightarrow$$

$$2500 + 125d^2 + d^4 + 25d^2 + d^4 = 200d^2 + 2d^4 \Rightarrow 2500 = 50d^2 \Rightarrow d^2 = 50 \Rightarrow$$

$d = 5\sqrt{2} \approx 7.071$ (for $0 \leq d \leq 10$). The third figure, a graph of $I(0) - I(5)$ with d independent, confirms that

$I(0) - I(5) = 0$, that is, $I(0) = I(5)$, when $d = 5\sqrt{2}$. Thus, the point of minimal illumination changes

abruptly from the midpoint to the endpoints when $d = 5\sqrt{2}$.

APPLIED PROJECT The Shape of a Can

1. In this case, the amount of metal used in the making of each top or bottom is $(2r)^2 = 4r^2$. So the quantity we want to minimize is $A = 2\pi rh + 2(4r^2)$. But $V = \pi r^2 h \Leftrightarrow h = V/\pi r^2$. Substituting this expression for h in A gives $A = 2V/r + 8r^2$. Differentiating A with respect to r , we get $dA/dr = -2V/r^2 + 16r = 0 \Rightarrow$

$$16r^3 = 2V = 2\pi r^2 h \Leftrightarrow \frac{h}{r} = \frac{8}{\pi} \approx 2.55. \text{ This gives a minimum because } \frac{d^2 A}{dr^2} = 16 + \frac{4V}{r^3} > 0.$$

2.

We need to find the area of metal used up by each end, that is, the area of each hexagon. We subdivide the hexagon into six congruent triangles, each sharing one side (s in the diagram) with the hexagon. We calculate the length of $s = 2r \tan \frac{\pi}{6} = \frac{2}{\sqrt{3}}r$, so the area of each triangle is $\frac{1}{2}sr = \frac{1}{\sqrt{3}}r^2$, and the total area of the hexagon is $6 \cdot \frac{1}{\sqrt{3}}r^2 = 2\sqrt{3}r^2$. So the quantity we want to minimize is $A = 2\pi rh + 2 \cdot 2\sqrt{3}r^2$.

Substituting for h as in Problem 1 and differentiating, we get $\frac{dA}{dr} = -\frac{2V}{r^2} + 8\sqrt{3}r$. Setting this equal to 0, we get

$$8\sqrt{3}r^3 = 2V = 2\pi r^2 h \Rightarrow \frac{h}{r} = \frac{4\sqrt{3}}{\pi} \approx 2.21. \text{ Again this minimizes } A \text{ because } \frac{d^2A}{dr^2} = 8\sqrt{3} + \frac{4V}{r^3} > 0.$$

3. Let $C = 4\sqrt{3}r^2 + 2\pi rh + k(4\pi r + h) = 4\sqrt{3}r^2 + 2\pi r\left(\frac{V}{\pi r^2}\right) + k\left(4\pi r + \frac{V}{\pi r^2}\right)$. Then

$$\frac{dC}{dr} = 8\sqrt{3}r - \frac{2V}{r^2} + 4k\pi - \frac{2kV}{\pi r^3}. \text{ Setting this equal to 0, dividing by 2 and substituting } \frac{V}{r^2} = \pi h \text{ and}$$

$$\frac{V}{\pi r^3} = \frac{h}{r} \text{ in the second and fourth terms respectively, we get } 0 = 4\sqrt{3}r - \pi h + 2k\pi - \frac{kh}{r} \Leftrightarrow$$

$$k\left(2\pi - \frac{h}{r}\right) = \pi h - 4\sqrt{3}r \Rightarrow \frac{k}{r} \frac{2\pi - h/r}{\pi h/r - 4\sqrt{3}} = 1. \text{ We now multiply by } \frac{\sqrt[3]{V}}{k}, \text{ noting that}$$

$$\frac{\sqrt[3]{V}}{k} \frac{k}{r} = \sqrt[3]{\frac{V}{r^3}} = \sqrt[3]{\frac{\pi h}{r}}, \text{ and get } \frac{\sqrt[3]{V}}{k} = \sqrt[3]{\frac{\pi h}{r}} \cdot \frac{2\pi - h/r}{\pi h/r - 4\sqrt{3}}.$$

4.

Let $\sqrt[3]{V}/k = T$ and $h/r = x$ so that $T(x) = \frac{2\pi - x}{\pi x - 4\sqrt{3}}$. We see

from the graph of T that when the ratio $\sqrt[3]{V}/k$ is large; that is, either the volume of the can is large or the cost of joining (proportional to k) is small, the optimum value of h/r is about 2.21, but when $\sqrt[3]{V}/k$ is small, indicating small volume or expensive joining, the optimum value of h/r is larger. (The part of the graph for $\sqrt[3]{V}/k < 0$ has no physical meaning, but confirms the location of the asymptote.)

5. Our conclusion is usually true in practice. But there are exceptions, such as cans of tuna, which may have to do with the shape of a reasonable slice of tuna. And for a comfortable grip on a soda or beer can, the geometry of the human hand is a restriction on the radius. Other possible considerations are packaging, transportation and stocking constraints, aesthetic appeal and other marketing concerns. Also, there may be better models than ours which prescribe a differently shaped can in special circumstances.

4.8 Applications to Business and Economics

1. (a) $C(0)$ represents the fixed costs of production, such as rent, utilities, machinery etc., which are incurred even when nothing is produced.
- (b) The inflection point is the point at which $C''(x)$ changes from negative to positive; that is, the marginal cost $C'(x)$ changes from decreasing to increasing. Thus, the marginal cost is minimized at the inflection point.

- (c) The marginal cost function is $C'(x)$. We graph it as in Example 1 in Section 3.2.

2. (a) We graph C' as in Example 1 in Section 3.2.

- (b) By reading values of $C(x)$ from its graph, we can plot $c(x) = C(x)/x$.

- (c) Since the graph in part (b) is decreasing, we estimate that the minimum value of $c(x)$ occurs at $x = 7$. The average cost and the marginal cost are equal at that value. See the box preceding Example 1.
3. $c(x) = 21.4 - 0.002x$ and $c(x) = C(x)/x \Rightarrow C(x) = 21.4x - 0.002x^2$. $C'(x) = 21.4 - 0.004x$ and $C'(1000) = 17.4$. This means that the cost of producing the 1001st unit is about \$17.40.

4. (a) Profit is maximized when the marginal revenue is equal to the marginal cost; that is, when R and C have equal slopes. See the box preceding Example 2.

- (b) $P(x) = R(x) - C(x)$ is sketched.

- (c) The marginal profit function is defined as $P'(x)$.

5. (a) The cost function is $C(x) = 40,000 + 300x + x^2$, so the cost at a production level of 1000 is $C(1000) = \$1,340,000$. The average cost function is $c(x) = \frac{C(x)}{x} = \frac{40,000}{x} + 300 + x$ and $c(1000) = \$1340/\text{unit}$. The marginal cost function is $C'(x) = 300 + 2x$ and $C'(1000) = \$2300/\text{unit}$.
- (b) See the box preceding Example 1. We must have $C'(x) = c(x) \Leftrightarrow 300 + 2x = \frac{40,000}{x} + 300 + x \Leftrightarrow x = \frac{40,000}{x} \Rightarrow x^2 = 40,000 \Rightarrow x = \sqrt{40,000} = 200$. This gives a minimum value of the average cost function $c(x)$ since $c''(x) = \frac{80,000}{x^3} > 0$.
- (c) The minimum average cost is $c(200) = \$700/\text{unit}$.
6. (a) $C(x) = 25,000 + 120x + 0.1x^2$, $C(1000) = \$245,000$. $c(x) = \frac{C(x)}{x} = \frac{25,000}{x} + 120 + 0.1x$, $c(1000) = \$245/\text{unit}$. $C'(x) = 120 + 0.2x$, $C'(1000) = \$320/\text{unit}$.
- (b) We must have $C'(x) = c(x) \Leftrightarrow 120 + 0.2x = \frac{25,000}{x} + 120 + 0.1x \Leftrightarrow 0.1x = \frac{25,000}{x} \Rightarrow 0.1x^2 = 25,000 \Rightarrow x = \sqrt{250,000} = 500$. This gives a minimum since $c''(x) = \frac{50,000}{x^3} > 0$.
- (c) The minimum average cost is $c(500) = \$220.00/\text{unit}$.
7. (a) $C(x) = 16,000 + 200x + 4x^{3/2}$, $C(1000) = 16,000 + 200,000 + 40,000\sqrt{10} \approx 216,000 + 126,491$, so $C(1000) \approx \$342,491$. $c(x) = C(x)/x = \frac{16,000}{x} + 200 + 4x^{1/2}$, $c(1000) \approx \$342.49/\text{unit}$. $C'(x) = 200 + 6x^{1/2}$, $C'(1000) = 200 + 60\sqrt{10} \approx \$389.74/\text{unit}$.
- (b) We must have $C'(x) = c(x) \Leftrightarrow 200 + 6x^{1/2} = \frac{16,000}{x} + 200 + 4x^{1/2} \Leftrightarrow 2x^{3/2} = 16,000 \Leftrightarrow x = (8,000)^{2/3} = 400$ units. To check that this is a minimum, we calculate $c'(x) = \frac{-16,000}{x^2} + \frac{2}{\sqrt{x}} = \frac{2}{x^2}(x^{3/2} - 8000)$. This is negative for $x < (8000)^{2/3} = 400$, zero at $x = 400$, and positive for $x > 400$, so c is decreasing on $(0, 400)$ and increasing on $(400, \infty)$. Thus, c has an absolute minimum at $x = 400$. [Note: $c''(x)$ is not positive for all $x > 0$.]
- (c) The minimum average cost is $c(400) = 40 + 200 + 80 = \$320/\text{unit}$.
8. (a) $C(x) = 10,000 + 340x - 0.3x^2 + 0.0001x^3$, $C(1000) = \$150,000$. $c(x) = C(x)/x = \frac{10,000}{x} + 340 - 0.3x + 0.0001x^2$, $c(1000) = \$150/\text{unit}$. $C'(x) = 340 - 0.6x + 0.0003x^2$, $C'(1000) = \$40/\text{unit}$.
- (b) We must have $C'(x) = c(x) \Leftrightarrow 340 - 0.6x + 0.0003x^2 = \frac{10,000}{x} + 340 - 0.3x + 0.0001x^2 \Leftrightarrow 0.0002x^2 = \frac{10,000}{x} + 0.3x \Leftrightarrow 0.0002x^3 - 0.3x^2 - 10,000 = 0 \Leftrightarrow x^3 - 1500x^2 - 50,000,000 = 0 \Rightarrow x \approx 1521.60 \approx 1522$ units. This gives a minimum since $c''(x) = \frac{20,000}{x^3} + 0.0002 > 0$.
- (c) The minimum average cost is about $c(1521.60) \approx \$121.62/\text{unit}$.
9. (a) $C(x) = 3700 + 5x - 0.04x^2 + 0.0003x^3 \Rightarrow C'(x) = 5 - 0.08x + 0.0009x^2$ (marginal cost). $c(x) = \frac{C(x)}{x} = \frac{3700}{x} + 5 - 0.04x + 0.0003x^2$ (average cost).

The graphs intersect at (208.51, 27.45), so the production level that minimizes average cost is about 209 units.

(c) $c'(x) = -\frac{3700}{x^2} - 0.04 + 0.0006x = 0 \Rightarrow 3700 + 0.04x^2 - 0.0006x^3 = 0 \Rightarrow x_1 \approx 208.51$.
 $c(x_1) \approx \$27.45/\text{unit}$.

(d) The marginal cost is given by $C'(x)$, so to find its minimum value we'll find the derivative of C' ; that is, C'' .
 $C''(x) = -0.08 + 0.0018x = 0 \Rightarrow x_1 = \frac{800}{18} = 44.4\bar{4}$. $C'(x_1) = \$3.22/\text{unit}$.
 $C'''(x) = 0.0018 > 0$ for all x , so this is the minimum marginal cost. C''' is the second derivative of C' .

10. (a) $C(x) = 339 + 25x - 0.09x^2 + 0.0004x^3 \Rightarrow C'(x) = 25 - 0.18x + 0.0012x^2$ (marginal cost).
 $c(x) = \frac{C(x)}{x} = \frac{339}{x} + 25 - 0.09x + 0.0004x^2$ (average cost).

The graphs intersect at (135.56, 22.65), so the production level that minimizes average cost is about 136 units.

(c) $c'(x) = -\frac{339}{x^2} - 0.09 + 0.0008x = 0 \Rightarrow x_1 \approx 135.56$. $c(x_1) \approx \$22.65/\text{unit}$.

(d) $C''(x) = -0.18 + 0.0024x = 0 \Rightarrow x = \frac{1800}{24} = 75$. $C'(75) = \$18.25/\text{unit}$.
 $C'''(x) = 0.0024 > 0$ for all x , so this is the minimum marginal cost.

11. $C(x) = 680 + 4x + 0.01x^2$, $p(x) = 12 \Rightarrow R(x) = xp(x) = 12x$. If the profit is maximum, then
 $R'(x) = C'(x) \Rightarrow 12 = 4 + 0.02x \Rightarrow 0.02x = 8 \Rightarrow x = 400$. The profit is maximized if $P''(x) < 0$,
but since $P''(x) = R''(x) - C''(x)$, we can just check the condition $R''(x) < C''(x)$. Now
 $R''(x) = 0 < 0.02 = C''(x)$, so $x = 400$ gives a maximum.

12. $C(x) = 680 + 4x + 0.01x^2$, $p(x) = 12 - x/500$. Then $R(x) = xp(x) = 12x - x^2/500$. If the profit is maximum, then $R'(x) = C'(x)$ [See the box preceding Example 2.] $\Leftrightarrow 12 - x/250 = 4 + 0.02x \Leftrightarrow 8 = 0.024x \Leftrightarrow x = 8/0.024 = \frac{1000}{3}$. The profit is maximized if $P''(x) < 0$, but since
 $P''(x) = R''(x) - C''(x)$, we can just check the condition $R''(x) < C''(x)$. Now
 $R''(x) = -\frac{1}{250} < 0.02 = C''(x)$, so $x = \frac{1000}{3}$ gives a maximum.

13. $C(x) = 1450 + 36x - x^2 + 0.001x^3$, $p(x) = 60 - 0.01x$. Then $R(x) = xp(x) = 60x - 0.01x^2$. If the profit is maximum, then $R'(x) = C'(x) \Leftrightarrow 60 - 0.02x = 36 - 2x + 0.003x^2 \Rightarrow 0.003x^2 - 1.98x - 24 = 0$. By the quadratic formula, $x = \frac{1.98 \pm \sqrt{(-1.98)^2 + 4(0.003)(24)}}{2(0.003)} = \frac{1.98 \pm \sqrt{4.2084}}{0.006}$. Since $x > 0$,
 $x \approx (1.98 + 2.05)/0.006 \approx 672$. Now $R''(x) = -0.02$ and $C''(x) = -2 + 0.006x \Rightarrow C''(672) = 2.032$
 $\Rightarrow R''(672) < C''(672) \Rightarrow$ there is a maximum at $x = 672$.

14. $C(x) = 16,000 + 500x - 1.6x^2 + 0.004x^3$, $p(x) = 1700 - 7x$. Then $R(x) = xp(x) = 1700x - 7x^2$. If the profit is maximum, then $R'(x) = C'(x) \Leftrightarrow 1700 - 14x = 500 - 3.2x + 0.012x^2 \Leftrightarrow 0.012x^2 + 10.8x - 1200 = 0 \Leftrightarrow x^2 + 900x - 100,000 = 0 \Leftrightarrow (x + 1000)(x - 100) = 0 \Leftrightarrow x = 100$ (since $x > 0$). The profit is maximized if $P''(x) < 0$, but since $P''(x) = R''(x) - C''(x)$, we can just check the condition $R''(x) < C''(x)$. Now $R''(x) = -14 < -3.2 + 0.024x = C''(x)$ for $x > 0$, so there is a maximum at $x = 100$.

15. $C(x) = 0.001x^3 - 0.3x^2 + 6x + 900$. The marginal cost is $C'(x) = 0.003x^2 - 0.6x + 6$.

$C'(x)$ is increasing when $C''(x) > 0 \Leftrightarrow 0.006x - 0.6 > 0 \Leftrightarrow x > 0.6/0.006 = 100$. So $C'(x)$ starts to increase when $x = 100$.

16. $C(x) = 0.0002x^3 - 0.25x^2 + 4x + 1500$. The marginal cost is $C'(x) = 0.0006x^2 - 0.50x + 4$.

$C'(x)$ is increasing when $C''(x) > 0 \Leftrightarrow 0.0012x - 0.5 > 0 \Leftrightarrow x > 0.5/0.0012 \approx 417$. So $C'(x)$ starts to increase when $x = 417$.

17. (a) $C(x) = 1200 + 12x - 0.1x^2 + 0.0005x^3$.

$$R(x) = xp(x) = 29x - 0.00021x^2.$$

Since the profit is maximized when $R'(x) = C'(x)$,

we examine the curves R and C in the figure, looking for x -values at which the slopes of the tangent lines are equal. It appears that $x = 200$ is a good estimate.

- (b) $R'(x) = C'(x) \Rightarrow 29 - 0.00042x = 12 - 0.2x + 0.0015x^2 \Rightarrow 0.0015x^2 - 0.19958x - 17 = 0 \Rightarrow x \approx 192.06$ (for $x > 0$). As in Exercise 11, $R''(x) < C''(x) \Rightarrow -0.00042 < -0.2 + 0.003x \Leftrightarrow 0.003x > 0.19958 \Leftrightarrow x > 66.5$. Our value of 192 is in this range, so we have a maximum profit when we produce 192 yards of fabric.

18. (a) Cost = setup cost + manufacturing cost $\Rightarrow C(x) = 500 + m(x) = 500 + 20x - 5x^{3/4} + 0.01x^2$.

We can solve $x(p) = 320 - 7.7p$ for p in terms of x to find the demand (or price) function.

$$x = 320 - 7.7p \Rightarrow 7.7p = 320 - x \Rightarrow p(x) = \frac{320 - x}{7.7}, \quad R(x) = xp(x) = \frac{320x - x^2}{7.7}.$$

- (b) $C'(x) = R'(x) \Rightarrow 20 - \frac{15}{4}x^{-1/4} + 0.02x = \frac{320 - 2x}{7.7} \Rightarrow x \approx 81.53$ planes, and $p(x) = \$30.97$ million. The maximum profit associated with these values is about \$463.59 million.

19. (a) We are given that the demand function p is linear and $p(27,000) = 10$, $p(33,000) = 8$, so the slope is

$$\frac{10 - 8}{27,000 - 33,000} = -\frac{1}{3000} \text{ and an equation of the line is } y - 10 = \left(-\frac{1}{3000}\right)(x - 27,000) \Rightarrow y = p(x) = -\frac{1}{3000}x + 19 = 19 - (x/3000).$$

- (b) The revenue is $R(x) = xp(x) = 19x - (x^2/3000) \Rightarrow R'(x) = 19 - (x/1500) = 0$ when $x = 28,500$.

Since $R''(x) = -1/1500 < 0$, the maximum revenue occurs when $x = 28,500 \Rightarrow$ the price is $p(28,500) = \$9.50$.

20. (a) Let $p(x)$ be the demand function. Then $p(x)$ is linear and $y = p(x)$ passes through $(20, 10)$ and $(18, 11)$, so the slope is $-\frac{1}{2}$ and an equation of the line is $y - 10 = -\frac{1}{2}(x - 20) \Leftrightarrow y = -\frac{1}{2}x + 20$. Thus, the demand is $p(x) = -\frac{1}{2}x + 20$ and the revenue is $R(x) = xp(x) = -\frac{1}{2}x^2 + 20x$.

(b) The cost is $C(x) = 6x$, so the profit is $P(x) = R(x) - C(x) = -\frac{1}{2}x^2 + 14x$. Then $0 = P'(x) = -x + 14$
 $\Rightarrow x = 14$. Since $P''(x) = -1 < 0$, the selling price for maximum profit is $p(14) = -\frac{1}{2}(14) + 20 = \13 .

21. (a) As in Example 3, we see that the demand function p is linear. We are given that $p(1000) = 450$ and deduce that $p(1100) = 440$, since a \$10 reduction in price increases sales by 100 per week. The slope for p is
 $\frac{440 - 450}{1100 - 1000} = -\frac{1}{10}$, so an equation is $p - 450 = -\frac{1}{10}(x - 1000)$ or $p(x) = -\frac{1}{10}x + 550$.

(b) $R(x) = xp(x) = -\frac{1}{10}x^2 + 550x$. $R'(x) = -\frac{1}{5}x + 550 = 0$ when $x = 5(550) = 2750$.
 $p(2750) = 275$, so the rebate should be $450 - 275 = \$175$.

(c) $C(x) = 68,000 + 150x \Rightarrow$
 $P(x) = R(x) - C(x) = -\frac{1}{10}x^2 + 550x - 68,000 - 150x = -\frac{1}{10}x^2 + 400x - 68,000$,
 $P'(x) = -\frac{1}{5}x + 400 = 0$ when $x = 2000$. $p(2000) = 350$. Therefore, the rebate to maximize profits should be $450 - 350 = \$100$.

22. Let x denote the number of \$10 increases in rent. Then the price is $p(x) = 800 + 10x$, and the number of units occupied is $100 - x$. Now the revenue is

$$\begin{aligned} R(x) &= (\text{rental price per unit}) \times (\text{number of units rented}) \\ &= (800 + 10x)(100 - x) = -10x^2 + 200x + 80,000 \text{ for } 0 \leq x \leq 100 \Rightarrow \end{aligned}$$

$R'(x) = -20x + 200 = 0 \Leftrightarrow x = 10$. This is a maximum since $R''(x) = -20 < 0$ for all x . Now we must check the value of $R(x) = (800 + 10x)(100 - x)$ at $x = 10$ and at the endpoints of the domain to see which value of x gives the maximum value of R . $R(0) = 80,000$, $R(10) = (900)(90) = 81,000$, and
 $R(100) = (1800)(0) = 0$. Thus, the maximum revenue of \$81,000/week occurs when 90 units are occupied at a rent of \$900/week.

23. If the reorder quantity is x , then the manager places $\frac{800}{x}$ orders per year. Storage costs for the year are

$\frac{1}{2}x \cdot 4 = 2x$ dollars. Handling costs are \$100 per delivery, for a total of $\frac{800}{x} \cdot 100 = \frac{80,000}{x}$ dollars. The total costs for the year are $C(x) = 2x + \frac{80,000}{x}$. To minimize $C(x)$, we calculate

$C'(x) = 2 - \frac{80,000}{x^2} = \frac{2}{x^2}(x^2 - 40,000)$. This is negative when $x < 200$, zero when $x = 200$, and positive when $x > 200$, so C is decreasing on $(0, 200)$ and increasing on $(200, \infty)$, reaching its absolute minimum when $x = 200$. Thus, the optimal reorder quantity is 200 cases. The manager will place 4 orders per year for a total cost of $C(200) = \$800$.

24. She will have A/n dollars after each withdrawal and 0 dollars just before the next withdrawal, so her average cash balance at any given time is $\frac{1}{2}(A/n + 0) = A/(2n)$. The transaction costs for n withdrawals are nT . The lost interest cost on the average cash balance is $[A/(2n)] \cdot R$. Thus, the total cost for n transactions is

$$C(n) = nT + \frac{AR}{2n}. \text{ Now } C'(n) = T - \frac{AR}{2n^2} \text{ and } C'(n) = 0 \Rightarrow \frac{AR}{2n^2} = T \Rightarrow n^2 = \frac{AR}{2T} \Rightarrow$$

$n = \sqrt{\frac{AR}{2T}}$, the value of n that minimizes total costs since $C''(n) = -\frac{AR}{n^3} < 0$. Thus, the optimal average cash

$$\text{balance is } \frac{A}{2n} = \frac{A\sqrt{2T}}{2\sqrt{AR}} = \frac{\sqrt{AT}}{\sqrt{2R}} = \sqrt{\frac{AT}{2R}}.$$

4.9 Newton's Method

1. (a)

The tangent line at $x = 1$ intersects the x -axis at $x \approx 2.3$, so $x_2 \approx 2.3$. The tangent line at $x = 2.3$ intersects the x -axis at $x \approx 3$, so $x_3 \approx 3.0$.

(b) $x_1 = 5$ would *not* be a better first approximation than $x_1 = 1$ since the tangent line is nearly horizontal. In fact, the second approximation for $x_1 = 5$ appears to be to the left of $x = 1$.

2.

The tangent line at $x = 9$ intersects the x -axis at $x \approx 6.0$, so $x_2 \approx 6.0$. The tangent line at $x = 6.0$ intersects the x -axis at $x \approx 8.0$, so $x_3 \approx 8.0$.

3. Since $x_1 = 3$ and $y = 5x - 4$ is tangent to $y = f(x)$ at $x = 3$, we simply need to find where the tangent line intersects the x -axis. $y = 0 \Rightarrow 5x_2 - 4 = 0 \Rightarrow x_2 = \frac{4}{5}$.

4. (a)

If $x_1 = 0$, then x_2 is negative, and x_3 is even more negative. The sequence of approximations does not converge, that is, Newton's method fails.

(b)

If $x_1 = 1$, the tangent line is horizontal and Newton's method fails.

(c)

If $x_1 = 3$, then $x_2 = 1$ and we have the same situation as in part (b). Newton's method fails again.

(d)

If $x_1 = 4$, the tangent line is horizontal and Newton's method fails.

(e)

If $x_1 = 5$, then x_2 is greater than 6, x_3 gets closer to 6, and the sequence of approximations converges to 6. Newton's method succeeds!

$$5. f(x) = x^3 + 2x - 4 \Rightarrow f'(x) = 3x^2 + 2, \text{ so } x_{n+1} = x_n - \frac{x_n^3 + 2x_n - 4}{3x_n^2 + 2}. \text{ Now } x_1 = 1 \Rightarrow$$

$$x_2 = 1 - \frac{1 + 2 - 4}{3 \cdot 1^2 + 2} = 1 - \frac{-1}{5} = 1.2 \Rightarrow x_3 = 1.2 - \frac{(1.2)^3 + 2(1.2) - 4}{3(1.2)^2 + 2} \approx 1.1797.$$

$$6. f(x) = x^3 - x^2 - 1 \Rightarrow f'(x) = 3x^2 - 2x, \text{ so } x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} = x_n - \frac{x_n^3 - x_n^2 - 1}{3x_n^2 - 2x_n}.$$

$$\text{Now } x_1 = 1 \Rightarrow x_2 = 1 - \frac{1 - 1 - 1}{3 - 2} = 2 \Rightarrow x_3 = 2 - \frac{2^3 - 2^2 - 1}{3 \cdot 2^2 - 2 \cdot 2} = 1.625.$$

$$7. f(x) = x^4 - 20 \Rightarrow f'(x) = 4x^3, \text{ so } x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} = x_n - \frac{x_n^4 - 20}{4x_n^3}.$$

$$\text{Now } x_1 = 2 \Rightarrow x_2 = 2 - \frac{2^4 - 20}{4(2)^3} = 2.125 \Rightarrow x_3 = 2.125 - \frac{(2.125)^4 - 20}{4(2.125)^3} \approx 2.1148.$$

$$8. f(x) = x^5 + 2 \Rightarrow f'(x) = 5x^4, \text{ so } x_{n+1} = x_n - \frac{x_n^5 + 2}{5x_n^4}. \text{ Now } x_1 = -1 \Rightarrow$$

$$x_2 = -1 - \frac{(-1)^5 + 2}{5 \cdot (-1)^4} = -1 - \frac{1}{5} = -1.2 \Rightarrow x_3 = -1.2 - \frac{(-1.2)^5 + 2}{5(-1.2)^4} \approx -1.1529.$$

$$9. f(x) = x^3 + x + 3 \Rightarrow f'(x) = 3x^2 + 1, \text{ so}$$

$$x_{n+1} = x_n - \frac{x_n^3 + x_n + 3}{3x_n^2 + 1}. \text{ Now } x_1 = -1 \Rightarrow$$

$$x_2 = -1 - \frac{(-1)^3 + (-1) + 3}{3(-1)^2 + 1} = -1 - \frac{-1 - 1 + 3}{3 + 1} = -1 - \frac{1}{4} = -1.25.$$

Newton's method follows the tangent line at $(-1, 1)$ down to its intersection with the x -axis at $(-1.25, 0)$, giving the second approximation $x_2 = -1.25$.

$$10. f(x) = x^4 - x - 1 \Rightarrow f'(x) = 4x^3 - 1, \text{ so}$$

$$x_{n+1} = x_n - \frac{x_n^4 - x_n - 1}{4x_n^3 - 1}. \text{ Now } x_1 = 1 \Rightarrow$$

$$x_2 = 1 - \frac{1^4 - 1 - 1}{4 \cdot 1^3 - 1} = 1 - \frac{-1}{3} = \frac{4}{3}. \text{ Newton's method follows the}$$

tangent line at $(1, -1)$ up to its intersection with the x -axis at $(\frac{4}{3}, 0)$, giving the second approximation $x_2 = \frac{4}{3}$.

$$11. \text{ To approximate } x = \sqrt[3]{30} \text{ (so that } x^3 = 30), \text{ we can take } f(x) = x^3 - 30. \text{ So } f'(x) = 3x^2, \text{ and thus,}$$

$$x_{n+1} = x_n - \frac{x_n^3 - 30}{3x_n^2}. \text{ Since } \sqrt[3]{27} = 3 \text{ and } 27 \text{ is close to } 30, \text{ we'll use } x_1 = 3. \text{ We need to find approximations}$$

$$\text{until they agree to eight decimal places. } x_1 = 3 \Rightarrow x_2 \approx 3.11111111, x_3 \approx 3.10723734,$$

$$x_4 \approx 3.10723251 \approx x_5. \text{ So } \sqrt[3]{30} \approx 3.10723251, \text{ to eight decimal places.}$$

Here is a quick and easy method for finding the iterations for Newton's method on a programmable calculator. (The screens shown are from the TI-83 Plus, but the method is similar on other calculators.) Assign $f(x) = x^3 - 30$ to Y_1 , and $f'(x) = 3x^2$ to Y_2 . Now store $x_1 = 3$ in X and then enter $X - Y_1/Y_2 \rightarrow X$ to get $x_2 = 3.\bar{1}$. By successively pressing the ENTER key, you get the approximations $x_3, x_4, \dots$

```

Plot1 Plot2 Plot3
Y1=X^3-30
Y2=3X^2
Y3=
Y4=
Y5=
Y6=
Y7=

```

```

3→X
X-Y1/Y2→X
3.111111111
3.107237339
3.107232506
3.107232506

```

In Derive, load the utility file SOLVE. Enter $\text{NEWTON}(x^3 - 30, x, 3)$ and then APPROXIMATE to get $[3, 3.11111111, 3.10723733, 3.10723250, 3.10723250]$. You can request a specific iteration by adding a fourth argument. For example, $\text{NEWTON}(x^3 - 30, x, 3, 2)$ gives $[3, 3.11111111, 3.10723733]$.

In Maple, make the assignments $f := x \rightarrow x^3 - 30$; $g := x \rightarrow x - f(x)/D(f)(x)$; and $x := 3$;. Repeatedly execute the command $x := g(x)$; to generate successive approximations.

In Mathematica, make the assignments $f[x_] := x^3 - 30$, $g[x_] := x - f[x]/f'[x]$, and $x = 3$. Repeatedly execute the command $x = g[x]$ to generate successive approximations.

12. $f(x) = x^7 - 1000 \Rightarrow f'(x) = 7x^6$, so $x_{n+1} = x_n - \frac{x_n^7 - 1000}{7x_n^6}$. We need to find approximations until they agree to eight decimal places. $x_1 = 3 \Rightarrow x_2 \approx 2.76739173$, $x_3 \approx 2.69008741$, $x_4 \approx 2.68275645$, $x_5 \approx 2.68269580 \approx x_6$. So $\sqrt[7]{1000} \approx 2.68269580$, to eight decimal places.
13. $f(x) = 2x^3 - 6x^2 + 3x + 1 \Rightarrow f'(x) = 6x^2 - 12x + 3 \Rightarrow x_{n+1} = x_n - \frac{2x_n^3 - 6x_n^2 + 3x_n + 1}{6x_n^2 - 12x_n + 3}$. We need to find approximations until they agree to six decimal places. $x_1 = 2.5 \Rightarrow x_2 \approx 2.285714$, $x_3 \approx 2.228824$, $x_4 \approx 2.224765$, $x_5 \approx 2.224745 \approx x_6$. So the root is 2.224745, to six decimal places.
14. $f(x) = x^4 + x - 4 \Rightarrow f'(x) = 4x^3 + 1 \Rightarrow x_{n+1} = x_n - \frac{x_n^4 + x_n - 4}{4x_n^3 + 1}$. $x_1 = 1.5 \Rightarrow x_2 \approx 1.323276$, $x_3 \approx 1.285346$, $x_4 \approx 1.283784$, $x_5 \approx 1.283782 \approx x_6$. So the root is 1.283782, to six decimal places.
15. $\sin x = x^2$, so $f(x) = \sin x - x^2 \Rightarrow f'(x) = \cos x - 2x \Rightarrow x_{n+1} = x_n - \frac{\sin x_n - x_n^2}{\cos x_n - 2x_n}$. From the figure, the positive root of $\sin x = x^2$ is near 1. $x_1 = 1 \Rightarrow x_2 \approx 0.891396$, $x_3 \approx 0.876985$, $x_4 \approx 0.876726 \approx x_5$. So the positive root is 0.876726, to six decimal places.

16. $2 \cos x = x^4$, so $f(x) = 2 \cos x - x^4 \Rightarrow f'(x) = -2 \sin x - 4x^3$

$$\Rightarrow x_{n+1} = x_n - \frac{2 \cos x_n - x_n^4}{-2 \sin x_n - 4x_n^3}. \text{ From the figure, the positive root}$$

of $2 \cos x = x^4$ is near 1. $x_1 = 1 \Rightarrow x_2 \approx 1.014184$,

$x_3 \approx 1.013958 \approx x_4$. So the positive root is 1.013958, to six decimal places.

17.

From the graph, we see that there appear to be points of intersection near

$x = -0.7$ and $x = 1.2$. Solving $x^4 = 1 + x$ is the same as solving

$$f(x) = x^4 - x - 1 = 0. f(x) = x^4 - x - 1 \Rightarrow f'(x) = 4x^3 - 1,$$

$$\text{so } x_{n+1} = x_n - \frac{x_n^4 - x_n - 1}{4x_n^3 - 1}.$$

$$x_1 = -0.7$$

$$x_2 \approx -0.725253$$

$$x_3 \approx -0.724493$$

$$x_4 \approx -0.724492 \approx x_5$$

$$x_1 = 1.2$$

$$x_2 \approx 1.221380$$

$$x_3 \approx 1.220745$$

$$x_4 \approx 1.220744 \approx x_5$$

To six decimal places, the roots of the equation are -0.724492 and 1.220744 .

18.

From the graph, we see that reasonable first approximations are $x = 0.5$

and $x = \pm 1.5$. $f(x) = x^5 - 5x + 2 \Rightarrow f'(x) = 5x^4 - 5$, so

$$x_{n+1} = x_n - \frac{x_n^5 - 5x_n + 2}{5x_n^4 - 5}.$$

$$x_1 = -1.5$$

$$x_2 \approx -1.593846$$

$$x_3 \approx -1.582241$$

$$x_4 \approx -1.582036 \approx x_5$$

$$x_1 = 0.5$$

$$x_2 \approx 0.4$$

$$x_3 \approx 0.402102 \approx x_4$$

$$x_1 = 1.5$$

$$x_2 \approx 1.396923$$

$$x_3 \approx 1.373078$$

$$x_4 \approx 1.371885$$

$$x_5 \approx 1.371882 \approx x_6$$

To six decimal places, the roots are -1.582036 , 0.402102 , and 1.371882 .

19.

From the graph, we see that there appear to be points of intersection near

$x = -0.5$ and $x = 1.5$. Solving $\sqrt[3]{x} = x^2 - 1$ is the same as solving

$$f(x) = \sqrt[3]{x} - x^2 + 1 = 0. f(x) = \sqrt[3]{x} - x^2 + 1 \Rightarrow$$

$$f'(x) = \frac{1}{3}x^{-2/3} - 2x, \text{ so } x_{n+1} = x_n - \frac{\sqrt[3]{x_n} - x_n^2 + 1}{\frac{1}{3}x_n^{-2/3} - 2x_n}.$$

$$x_1 = -0.5$$

$$x_2 \approx -0.471421$$

$$x_3 \approx -0.471074 \approx x_4$$

$$x_1 = 1.5$$

$$x_2 \approx 1.461653$$

$$x_3 \approx 1.461070 \approx x_4$$

To six decimal places, the roots are -0.471074 and 1.461070 .

20.

From the graph, we see that there appear to be points of intersection near

$x = -1.2$ and $x = 1.5$. Solving $\sqrt{x+3} = x^2$ is the same as solving

$$f(x) = x^2 - \sqrt{x+3} = 0. \quad f'(x) = 2x - \frac{1}{2\sqrt{x+3}} \Rightarrow$$

$$f'(x) = 2x - \frac{1}{2\sqrt{x+3}}, \text{ so } x_{n+1} = x_n - \frac{x_n^2 - \sqrt{x_n+3}}{2x_n - 1/(2\sqrt{x_n+3})}.$$

$$\begin{array}{ll} x_1 = -1.2 & x_1 = 1.5 \\ x_2 \approx -1.164526 & x_2 \approx 1.453449 \\ x_3 \approx -1.164035 \approx x_4 & x_3 \approx 1.452627 \approx x_4 \end{array}$$

To six decimal places, the roots of the equation are -1.164035 and 1.452627 .

21. From the graph, there appears to be a point of intersection near $x = 0.6$.

Solving $\cos x = \sqrt{x}$ is the same as solving $f(x) = \cos x - \sqrt{x} = 0$.

$$f(x) = \cos x - \sqrt{x} \Rightarrow f'(x) = -\sin x - 1/(2\sqrt{x}), \text{ so}$$

$$x_{n+1} = x_n - \frac{\cos x_n - \sqrt{x_n}}{-\sin x_n - 1/(2\sqrt{x_n})}. \text{ Now } x_1 = 0.6 \Rightarrow$$

$x_2 \approx 0.641928, x_3 \approx 0.641714 \approx x_4$. To six decimal places, the root of the equation is 0.641714 .

22. From the graph, there appears to be a point of intersection near $x = 0.7$.

Solving $\tan x = \sqrt{1-x^2}$ is the same as solving

$$f(x) = \tan x - \sqrt{1-x^2} = 0. \quad f'(x) = \tan x - \sqrt{1-x^2} \Rightarrow$$

$$f'(x) = \sec^2 x + x/\sqrt{1-x^2}, \text{ so } x_{n+1} = x_n - \frac{\tan x_n - \sqrt{1-x_n^2}}{\sec^2 x_n + x_n/\sqrt{1-x_n^2}}.$$

$$x_1 = 0.7 \Rightarrow x_2 \approx 0.652356, x_3 \approx 0.649895, x_4 \approx 0.649889 \approx x_5.$$

To six decimal places, the root of the equation is 0.649889 .

23.

$$f(x) = x^5 - x^4 - 5x^3 - x^2 + 4x + 3 \Rightarrow$$

$$f'(x) = 5x^4 - 4x^3 - 15x^2 - 2x + 4 \Rightarrow$$

$$x_{n+1} = x_n - \frac{x_n^5 - x_n^4 - 5x_n^3 - x_n^2 + 4x_n + 3}{5x_n^4 - 4x_n^3 - 15x_n^2 - 2x_n + 4}. \text{ From the graph of } f,$$

there appear to be roots near $-1.4, 1.1,$ and 2.7 .

$$\begin{array}{lll} x_1 = -1.4 & x_1 = 1.1 & x_1 = 2.7 \\ x_2 \approx -1.39210970 & x_2 \approx 1.07780402 & x_2 \approx 2.72046250 \\ x_3 \approx -1.39194698 & x_3 \approx 1.07739442 & x_3 \approx 2.71987870 \\ x_4 \approx -1.39194691 \approx x_5 & x_4 \approx 1.07739428 \approx x_5 & x_4 \approx 2.71987822 \approx x_5 \end{array}$$

To eight decimal places, the roots of the equation are $-1.39194691, 1.07739428,$ and 2.71987822 .

24.

Solving $x^2(4 - x^2) = \frac{4}{x^2 + 1}$ is the same as solving

$$f(x) = 4x^2 - x^4 - \frac{4}{x^2 + 1} = 0. \quad f'(x) = 8x - 4x^3 + \frac{8x}{(x^2 + 1)^2} \Rightarrow$$

$$x_{n+1} = x_n - \frac{4x_n^2 - x_n^4 - 4/(x_n^2 + 1)}{8x_n - 4x_n^3 + 8x_n/(x_n^2 + 1)^2}. \quad \text{From the graph of } f(x),$$

there appear to be roots near $x = \pm 1.9$ and $x = \pm 0.8$. Since f is even, we only need to find the positive roots.

$$x_1 = 0.8$$

$$x_1 = 1.9$$

$$x_2 \approx 0.84287645$$

$$x_2 \approx 1.94689103$$

$$x_3 \approx 0.84310820$$

$$x_3 \approx 1.94383891$$

$$x_4 \approx 0.84310821 \approx x_5$$

$$x_4 \approx 1.94382538 \approx x_5$$

To eight decimal places, the roots of the equation are ± 0.84310821 and ± 1.94382538 .

25.

From the graph, $y = x^2\sqrt{2 - x - x^2}$ and $y = 1$ intersect twice, at

$$x \approx -2 \text{ and at } x \approx -1. \quad f(x) = x^2\sqrt{2 - x - x^2} - 1 \Rightarrow$$

$$\begin{aligned} f'(x) &= x^2 \cdot \frac{1}{2}(2 - x - x^2)^{-1/2}(-1 - 2x) + (2 - x - x^2)^{1/2} \cdot 2x \\ &= \frac{1}{2}x(2 - x - x^2)^{-1/2} [x(-1 - 2x) + 4(2 - x - x^2)] \\ &= \frac{x(8 - 5x - 6x^2)}{2\sqrt{(2+x)(1-x)}}, \end{aligned}$$

so $x_{n+1} = x_n - \frac{x_n^2\sqrt{2 - x_n - x_n^2} - 1}{\frac{x_n(8 - 5x_n - 6x_n^2)}{2\sqrt{(2+x_n)(1-x_n)}}}$. Trying $x_1 = -2$ won't work because $f'(-2)$ is undefined, so we'll

try $x_1 = -1.95$.

$$x_1 = -1.95$$

$$x_1 = -0.8$$

$$x_2 \approx -1.98580357$$

$$x_2 \approx -0.82674444$$

$$x_3 \approx -1.97899778$$

$$x_3 \approx -0.82646236$$

$$x_4 \approx -1.97807848$$

$$x_4 \approx -0.82646233 \approx x_5$$

$$x_5 \approx -1.97806682$$

$$x_6 \approx -1.97806681 \approx x_7$$

To eight decimal places, the roots of the equation are -1.97806681 and -0.82646233 .

26.

From the equations $y = 3 \sin(x^2)$ and $y = 2x$ and the graph, we deduce that one root of the equation $3 \sin(x^2) = 2x$ is $x = 0$. We also see that the graphs intersect at approximately $x = 0.7$ and $x = 1.4$.

$$f(x) = 3 \sin(x^2) - 2x \Rightarrow f'(x) = 3 \cos(x^2) \cdot 2x - 2, \text{ so}$$

$$x_{n+1} = x_n - \frac{3 \sin(x_n^2) - 2x_n}{6x_n \cos(x_n^2) - 2}.$$

$$x_1 = 0.7$$

$$x_1 = 1.4$$

$$x_2 \approx 0.69303689$$

$$x_2 \approx 1.39530295$$

$$x_3 \approx 0.69299996 \approx x_4$$

$$x_3 \approx 1.39525078$$

$$x_4 \approx 1.39525077 \approx x_5$$

To eight decimal places, the roots of the equation are 0.69299996 and 1.39525077 .

27. (a) $f(x) = x^2 - a \Rightarrow f'(x) = 2x$, so Newton's method gives

$$x_{n+1} = x_n - \frac{x_n^2 - a}{2x_n} = x_n - \frac{1}{2}x_n + \frac{a}{2x_n} = \frac{1}{2}x_n + \frac{a}{2x_n} = \frac{1}{2}\left(x_n + \frac{a}{x_n}\right).$$

- (b) Using (a) with $a = 1000$ and $x_1 = \sqrt{900} = 30$, we get $x_2 \approx 31.666667$, $x_3 \approx 31.622807$, and $x_4 \approx 31.622777 \approx x_5$. So $\sqrt{1000} \approx 31.622777$.

28. (a) $f(x) = \frac{1}{x} - a \Rightarrow f'(x) = -\frac{1}{x^2}$, so $x_{n+1} = x_n - \frac{1/x_n - a}{-1/x_n^2} = x_n + x_n - ax_n^2 = 2x_n - ax_n^2$.

- (b) Using (a) with $a = 1.6894$ and $x_1 = \frac{1}{2} = 0.5$, we get $x_2 = 0.5754$, $x_3 \approx 0.588485$, and $x_4 \approx 0.588789 \approx x_5$. So $1/1.6894 \approx 0.588789$.

29. $f(x) = x^3 - 3x + 6 \Rightarrow f'(x) = 3x^2 - 3$. If $x_1 = 1$, then $f'(x_1) = 0$ and the tangent line used for approximating x_2 is horizontal. Attempting to find x_2 results in trying to divide by zero.

30. $x^3 - x = 1 \Leftrightarrow x^3 - x - 1 = 0$. $f(x) = x^3 - x - 1 \Rightarrow f'(x) = 3x^2 - 1$, so $x_{n+1} = x_n - \frac{x_n^3 - x_n - 1}{3x_n^2 - 1}$.

(a) $x_1 = 1$, $x_2 = 1.5$, $x_3 \approx 1.347826$, $x_4 \approx 1.325200$, $x_5 \approx 1.324718 \approx x_6$

(b) $x_1 = 0.6$, $x_2 = 17.9$, $x_3 \approx 11.946802$, $x_4 \approx 7.985520$, $x_5 \approx 5.356909$, $x_6 \approx 3.624996$, $x_7 \approx 2.505589$, $x_8 \approx 1.820129$, $x_9 \approx 1.461044$, $x_{10} \approx 1.339323$, $x_{11} \approx 1.324913$, $x_{12} \approx 1.324718 \approx x_{13}$

(c) $x_1 = 0.57$, $x_2 \approx -54.165455$, $x_3 \approx -36.114293$, $x_4 \approx -24.082094$, $x_5 \approx -16.063387$, $x_6 \approx -10.721483$, $x_7 \approx -7.165534$, $x_8 \approx -4.801704$, $x_9 \approx -3.233425$, $x_{10} \approx -2.193674$, $x_{11} \approx -1.496867$, $x_{12} \approx -0.997546$, $x_{13} \approx -0.496305$, $x_{14} \approx -2.894162$, $x_{15} \approx -1.967962$, $x_{16} \approx -1.341355$, $x_{17} \approx -0.870187$, $x_{18} \approx -0.249949$, $x_{19} \approx -1.192219$, $x_{20} \approx -0.731952$, $x_{21} \approx 0.355213$, $x_{22} \approx -1.753322$, $x_{23} \approx -1.189420$, $x_{24} \approx -0.729123$, $x_{25} \approx 0.377844$, $x_{26} \approx -1.937872$, $x_{27} \approx -1.320350$, $x_{28} \approx -0.851919$, $x_{29} \approx -0.200959$, $x_{30} \approx -1.119386$, $x_{31} \approx -0.654291$, $x_{32} \approx 1.547010$, $x_{33} \approx 1.360051$, $x_{34} \approx 1.325828$, $x_{35} \approx 1.324719$, $x_{36} \approx 1.324718 \approx x_{37}$.

From the figure, we see that the tangent line corresponding to $x_1 = 1$ results in a sequence of approximations that converges quite quickly ($x_5 \approx x_6$). The tangent line corresponding to $x_1 = 0.6$ is close to being horizontal, so x_2 is quite far from the root. But the sequence still converges — just a little more slowly ($x_{12} \approx x_{13}$). Lastly, the tangent line corresponding to $x_1 = 0.57$ is very nearly horizontal, x_2 is farther away from the root, and the sequence takes more iterations to converge ($x_{36} \approx x_{37}$).

31. For $f(x) = x^{1/3}$, $f'(x) = \frac{1}{3}x^{-2/3}$ and

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} = x_n - \frac{x_n^{1/3}}{\frac{1}{3}x_n^{-2/3}} = x_n - 3x_n = -2x_n.$$

Therefore, each successive approximation becomes twice as large as the previous one in absolute value, so the sequence of approximations fails to converge to the root, which is 0. In the figure, we have $x_1 = 0.5$,

$$x_2 = -2(0.5) = -1, \text{ and } x_3 = -2(-1) = 2.$$

32. According to Newton's Method, for
- $x_n > 0$
- ,

$$x_{n+1} = x_n - \frac{\sqrt{x_n}}{1/(2\sqrt{x_n})} = x_n - 2x_n = -x_n \text{ and for } x_n < 0,$$

$$x_{n+1} = x_n - \frac{-\sqrt{-x_n}}{1/(2\sqrt{-x_n})} = x_n - [-2(-x_n)] = -x_n. \text{ So we can}$$

see that after choosing any value x_1 the subsequent values will alternate between $-x_1$ and x_1 and never approach the root.

33. (a)
- $f(x) = 3x^4 - 28x^3 + 6x^2 + 24x \Rightarrow f'(x) = 12x^3 - 84x^2 + 12x + 24 \Rightarrow$

$$f''(x) = 36x^2 - 168x + 12. \text{ Now to solve } f'(x) = 0, \text{ try } x_1 = \frac{1}{2} \Rightarrow x_2 = x_1 - \frac{f'(x_1)}{f''(x_1)} = \frac{2}{3} \Rightarrow$$

$$x_3 \approx 0.6455 \Rightarrow x_4 \approx 0.6452 \Rightarrow x_5 \approx 0.6452. \text{ Now try } x_1 = 6 \Rightarrow x_2 = 7.12 \Rightarrow$$

$$x_3 \approx 6.8353 \Rightarrow x_4 \approx 6.8102 \Rightarrow x_5 \approx 6.8100. \text{ Finally try } x_1 = -0.5 \Rightarrow x_2 \approx -0.4571 \Rightarrow$$

$$x_3 \approx -0.4552 \Rightarrow x_4 \approx -0.4552. \text{ Therefore, } x = -0.455, 6.810 \text{ and } 0.645 \text{ are all critical numbers correct to three decimal places.}$$

- (b) $f(-1) = 13, f(7) = -1939, f(6.810) \approx -1949.07, f(-0.455) \approx -6.912, f(0.645) \approx 10.982$. Therefore, $f(6.810) \approx -1949.07$ is the absolute minimum correct to two decimal places.

34. $f(x) = x^2 + \sin x \Rightarrow f'(x) = 2x + \cos x$. $f'(x)$ exists for all x , so to find the minimum of f , we can examine the zeros of f' . From the graph of f' , we see that a good choice for x_1 is $x_1 = -0.5$. Use $g(x) = 2x + \cos x$ and $g'(x) = 2 - \sin x$ to obtain $x_2 \approx -0.450627$,

$$x_3 \approx -0.450184 \approx x_4. \text{ Since } f''(x) = 2 - \sin x > 0 \text{ for all } x,$$

$$f(-0.450184) \approx -0.232466 \text{ is the absolute minimum.}$$

35. $y = x^3 + \cos x \Rightarrow y' = 3x^2 - \sin x \Rightarrow y'' = 6x - \cos x \Rightarrow y''' = 6 + \sin x$. Now to solve $y'' = 0$, try $x_1 = 0$, and then $x_2 = x_1 - \frac{y''(x_1)}{y'''(x_1)} = \frac{1}{6} \Rightarrow x_3 \approx 0.164419 \approx x_4$. For $x < 0.164419$, $y'' < 0$, and for $x > 0.164419$, $y'' > 0$. Therefore, the point of inflection, correct to six decimal places, is $(0.164419, y(0.164419)) \approx (0.164419, 0.990958)$.

- 36.

$f(x) = -\sin x \Rightarrow f'(x) = -\cos x$. At $x = a$, the slope of the tangent line is $f'(a) = -\cos a$. The line through the origin and $(a, f(a))$ is $y = \frac{-\sin a - 0}{a - 0}x$. If this line is to be tangent to f at $x = a$, then its

$$\text{slope must equal } f'(a). \text{ Thus, } \frac{-\sin a}{a} = -\cos a \Rightarrow \tan a = a.$$

To solve this equation using Newton's method, let $g(x) = \tan x - x$,

$$g'(x) = \sec^2 x - 1, \text{ and } x_{n+1} = x_n - \frac{\tan x_n - x_n}{\sec^2 x_n - 1} \text{ with } x_1 = 4.5 \text{ (estimated from the figure). } x_2 \approx 4.493614,$$

$$x_3 \approx 4.493410, x_4 \approx 4.493409 \approx x_5. \text{ Thus, the slope of the line that has the largest slope is } f'(x_5) \approx 0.217234.$$

37.

The volume of the silo, in terms of its radius, is

$$V(r) = \pi r^2(30) + \frac{1}{2}\left(\frac{4}{3}\pi r^3\right) = 30\pi r^2 + \frac{2}{3}\pi r^3.$$

From a graph of V , we see that $V(r) = 15,000$ at $r \approx 11$ ft. Now we use Newton's method to solve the equation $V(r) - 15,000 = 0$.

$\frac{dV}{dr} = 60\pi r + 2\pi r^2$, so $r_{n+1} = r_n - \frac{30\pi r_n^2 + \frac{2}{3}\pi r_n^3 - 15,000}{60\pi r_n + 2\pi r_n^2}$. Taking $r_1 = 11$, we get $r_2 \approx 11.2853$, $r_3 \approx 11.2807 \approx r_4$. So in order for the silo to hold $15,000 \text{ ft}^3$ of grain, its radius must be about 11.2807 ft.

38. Let the radius of the circle be r . Using $s = r\theta$, we have $5 = r\theta$ and so $r = 5/\theta$. From the Law of Cosines we get

$$4^2 = r^2 + r^2 - 2 \cdot r \cdot r \cdot \cos \theta \Leftrightarrow 16 = 2r^2(1 - \cos \theta) = 2(5/\theta)^2(1 - \cos \theta).$$

Multiplying by θ^2 gives $16\theta^2 = 50(1 - \cos \theta)$, so we take

$$f(\theta) = 16\theta^2 + 50 \cos \theta - 50 \text{ and } f'(\theta) = 32\theta - 50 \sin \theta. \text{ The formula}$$

for Newton's method is $\theta_{n+1} = \theta_n - \frac{16\theta_n^2 + 50 \cos \theta_n - 50}{32\theta_n - 50 \sin \theta_n}$. From the

graph of f , we can use $\theta_1 = 2.2$, giving us $\theta_2 \approx 2.2662$,

$\theta_3 \approx 2.2622 \approx \theta_4$. So correct to four decimal places, the angle is 2.2622 radians $\approx 130^\circ$.

39. In this case, $A = 18,000$, $R = 375$, and $n = 5(12) = 60$. So the formula $A = \frac{R}{i} [1 - (1+i)^{-n}]$ becomes

$$18,000 = \frac{375}{x} [1 - (1+x)^{-60}] \Leftrightarrow 48x = 1 - (1+x)^{-60} \quad [\text{multiply each term by } (1+x)^{60}] \Leftrightarrow$$

$$48x(1+x)^{60} - (1+x)^{60} + 1 = 0. \text{ Let the LHS be called } f(x), \text{ so that}$$

$$\begin{aligned} f'(x) &= 48x(60)(1+x)^{59} + 48(1+x)^{60} - 60(1+x)^{59} \\ &= 12(1+x)^{59} [4x(60) + 4(1+x) - 5] = 12(1+x)^{59} (244x - 1) \end{aligned}$$

$$x_{n+1} = x_n - \frac{48x_n(1+x_n)^{60} - (1+x_n)^{60} + 1}{12(1+x_n)^{59} (244x_n - 1)}. \text{ An interest rate of } 1\% \text{ per month seems like a reasonable}$$

estimate for $x = i$. So let $x_1 = 1\% = 0.01$, and we get $x_2 \approx 0.0082202$, $x_3 \approx 0.0076802$, $x_4 \approx 0.0076291$, $x_5 \approx 0.0076286 \approx x_6$. Thus, the dealer is charging a monthly interest rate of 0.76286% (or 9.55% per year, compounded monthly).

40. (a) $p(x) = x^5 - (2+r)x^4 + (1+2r)x^3 - (1-r)x^2 + 2(1-r)x + r - 1 \Rightarrow$

$$p'(x) = 5x^4 - 4(2+r)x^3 + 3(1+2r)x^2 - 2(1-r)x + 2(1-r). \text{ So we use}$$

$$x_{n+1} = x_n - \frac{x_n^5 - (2+r)x_n^4 + (1+2r)x_n^3 - (1-r)x_n^2 + 2(1-r)x_n + r - 1}{5x_n^4 - 4(2+r)x_n^3 + 3(1+2r)x_n^2 - 2(1-r)x_n + 2(1-r)}. \text{ We substitute in the value}$$

$r \approx 3.04042 \times 10^{-6}$ in order to evaluate the approximations numerically. The libration point L_1 is slightly less than 1 AU from the Sun, so we take $x_1 = 0.95$ as our first approximation, and get $x_2 \approx 0.96682$,

$$x_3 \approx 0.97770, x_4 \approx 0.98451, x_5 \approx 0.98830, x_6 \approx 0.98976, x_7 \approx 0.98998, x_8 \approx 0.98999 \approx x_9.$$

So, to five decimal places, L_1 is located 0.98999 AU from the Sun (or 0.01001 AU from Earth).

(b) In this case we use Newton's method with the function

$$p(x) - 2rx^2 = x^5 - (2+r)x^4 + (1+2r)x^3 - (1+r)x^2 + 2(1-r)x + r - 1 \Rightarrow$$

$$[p(x) - 2rx^2]' = 5x^4 - 4(2+r)x^3 + 3(1+2r)x^2 - 2(1+r)x + 2(1-r). \text{ So}$$

$$x_{n+1} = x_n - \frac{x_n^5 - (2+r)x_n^4 + (1+2r)x_n^3 - (1+r)x_n^2 + 2(1-r)x_n + r - 1}{5x_n^4 - 4(2+r)x_n^3 + 3(1+2r)x_n^2 - 2(1+r)x_n + 2(1-r)}.$$
 Again, we substitute

$r \approx 3.04042 \times 10^{-6}$. L_2 is slightly more than 1 AU from the Sun and, judging from the result of part (a), probably less than 0.02 AU from Earth. So we take $x_1 = 1.02$ and get $x_2 \approx 1.01422$, $x_3 \approx 1.01118$, $x_4 \approx 1.01018$, $x_5 \approx 1.01008 \approx x_6$. So, to five decimal places, L_2 is located 1.01008 AU from the Sun (or 0.01008 AU from Earth).

4.10 Antiderivatives

$$1. f(x) = 6x^2 - 8x + 3 \Rightarrow F(x) = 6 \frac{x^{2+1}}{2+1} - 8 \frac{x^{1+1}}{1+1} + 3x + C = 2x^3 - 4x^2 + 3x + C$$

$$\text{Check: } F'(x) = 2 \cdot 3x^2 - 4 \cdot 2x + 3 + 0 = 6x^2 - 8x + 3 = f(x)$$

$$2. f(x) = 4 + x^2 - 5x^3 \Rightarrow F(x) = 4x + \frac{1}{3}x^3 - \frac{5}{4}x^4 + C$$

$$3. f(x) = 1 - x^3 + 5x^5 - 3x^7 \Rightarrow F(x) = x - \frac{x^{3+1}}{3+1} + 5 \frac{x^{5+1}}{5+1} - 3 \frac{x^{7+1}}{7+1} + C = x - \frac{1}{4}x^4 + \frac{5}{6}x^6 - \frac{3}{8}x^8 + C$$

$$4. f(x) = x^{20} + 4x^{10} + 8 \Rightarrow F(x) = \frac{1}{21}x^{21} + \frac{4}{11}x^{11} + 8x + C$$

$$5. f(x) = 5x^{1/4} - 7x^{3/4} \Rightarrow F(x) = 5 \frac{x^{1/4+1}}{\frac{1}{4}+1} - 7 \frac{x^{3/4+1}}{\frac{3}{4}+1} + C = 5 \frac{x^{5/4}}{5/4} - 7 \frac{x^{7/4}}{7/4} + C = 4x^{5/4} - 4x^{7/4} + C$$

$$6. f(x) = 2x + 3x^{1.7} \Rightarrow F(x) = x^2 + \frac{3}{2.7}x^{2.7} + C = x^2 + \frac{10}{9}x^{2.7} + C$$

$$7. f(x) = 6\sqrt{x} - \frac{8}{\sqrt{x}} = 6x^{1/2} - x^{-1/2} \Rightarrow$$

$$F(x) = 6 \frac{x^{1/2+1}}{\frac{1}{2}+1} - \frac{x^{-1/2+1}}{-1/2+1} + C = 6 \frac{x^{3/2}}{3/2} - \frac{x^{1/2}}{1/2} + C = 4x^{3/2} - \frac{6}{7}x^{7/6} + C$$

$$8. f(x) = \sqrt[4]{x^3} + \sqrt[3]{x^4} = x^{3/4} + x^{4/3} \Rightarrow F(x) = \frac{x^{7/4}}{7/4} + \frac{x^{7/3}}{7/3} + C = \frac{4}{7}x^{7/4} + \frac{3}{7}x^{7/3} + C$$

$$9. f(x) = \frac{10}{x^9} = 10x^{-9} \text{ has domain } (-\infty, 0) \cup (0, \infty), \text{ so } F(x) = \begin{cases} \frac{10x^{-8}}{-8} + C_1 = -\frac{5}{4x^8} + C_1 & \text{if } x < 0 \\ -\frac{5}{4x^8} + C_2 & \text{if } x > 0 \end{cases}$$

See Example 1 for a similar problem.

$$10. g(x) = \frac{5 - 4x^3 + 2x^6}{x^6} = 5x^{-6} - 4x^{-3} + 2 \text{ has domain } (-\infty, 0) \cup (0, \infty), \text{ so}$$

$$G(x) = \begin{cases} 5 \frac{x^{-5}}{-5} - 4 \frac{x^{-2}}{-2} + 2x + C_1 = -\frac{1}{x^5} + \frac{2}{x^2} + 2x + C_1 & \text{if } x < 0 \\ -\frac{1}{x^5} + \frac{2}{x^2} + 2x + C_2 & \text{if } x > 0 \end{cases}$$

$$11. f(u) = \frac{u^4 + 3\sqrt{u}}{u^2} = \frac{u^4}{u^2} + \frac{3u^{1/2}}{u^2} = u^2 + 3u^{-3/2} \Rightarrow$$

$$F(u) = \frac{u^3}{3} + 3 \frac{u^{-3/2+1}}{-3/2+1} + C = \frac{1}{3}u^3 + 3 \frac{u^{-1/2}}{-1/2} + C = \frac{1}{3}u^3 - \frac{6}{\sqrt{u}} + C$$

12. $f(x) = x^{2/3} + 2x^{-1/3}$ has domain $(-\infty, 0) \cup (0, \infty)$, so

$$F(x) = \begin{cases} \frac{x^{5/3}}{5/3} + \frac{2x^{2/3}}{2/3} + C_1 = \frac{3}{5}x^{5/3} + 3x^{2/3} + C_1 & \text{if } x > 0 \\ \frac{3}{5}x^{5/3} + 3x^{2/3} + C_2 & \text{if } x < 0 \end{cases}$$

13. $h(x) = x^3 + 5 \sin x \Rightarrow H(x) = \frac{1}{4}x^4 + 5(-\cos x) + C = \frac{1}{4}x^4 - 5 \cos x + C$

14. $f(t) = 3 \cos t - 4 \sin t \Rightarrow F(t) = 3(\sin t) - 4(-\cos t) + C = 3 \sin t + 4 \cos t + C$

15. $f(t) = 4\sqrt{t} - \sec t \tan t \Rightarrow F(t) = \frac{4}{3/2}t^{3/2} - \sec t + C = \frac{8}{3}t^{3/2} - \sec t + C_n$ on the interval $(n\pi - \frac{\pi}{2}, n\pi + \frac{\pi}{2})$.

16. $f(\theta) = 6\theta^2 - 7 \sec^2 \theta \Rightarrow F(\theta) = 2\theta^3 - 7 \tan \theta + C_n$ on the interval $(n\pi - \frac{\pi}{2}, n\pi + \frac{\pi}{2})$.

17. $f''(x) = 6x + 12x^2 \Rightarrow f'(x) = 6 \cdot \frac{x^2}{2} + 12 \cdot \frac{x^3}{3} + C = 3x^2 + 4x^3 + C \Rightarrow$

$$f(x) = 3 \cdot \frac{x^3}{3} + 4 \cdot \frac{x^4}{4} + Cx + D = x^3 + x^4 + Cx + D \quad [C \text{ and } D \text{ are just arbitrary constants}]$$

18. $f''(x) = 2 + x^3 + x^6 \Rightarrow f'(x) = 2x + \frac{1}{4}x^4 + \frac{1}{7}x^7 + C \Rightarrow f(x) = x^2 + \frac{1}{20}x^5 + \frac{1}{56}x^8 + Cx + D$

19. $f''(x) = 1 + x^{4/5} \Rightarrow f'(x) = x + \frac{5}{9}x^{9/5} + C \Rightarrow$

$$f(x) = \frac{1}{2}x^2 + \frac{5}{9} \cdot \frac{5}{14}x^{14/5} + Cx + D = \frac{1}{2}x^2 + \frac{25}{126}x^{14/5} + Cx + D$$

20. $f''(x) = \cos x \Rightarrow f'(x) = \sin x + C \Rightarrow f(x) = -\cos x + Cx + D$

21. $f'''(t) = 60t^2 \Rightarrow f''(t) = 20t^3 + C \Rightarrow f'(t) = 5t^4 + Ct + D \Rightarrow f(t) = t^5 + \frac{1}{2}Ct^2 + Dt + E$

22. $f'''(t) = t - \sqrt{t} \Rightarrow f''(t) = \frac{1}{2}t^2 - \frac{2}{3}t^{3/2} + C \Rightarrow f'(t) = \frac{1}{6}t^3 - \frac{4}{15}t^{5/2} + Ct + D \Rightarrow$

$$f(t) = \frac{1}{24}t^4 - \frac{8}{105}t^{7/2} + \frac{1}{2}Ct^2 + Dt + E$$

23. $f'(x) = 1 - 6x \Rightarrow f(x) = x - 3x^2 + C. f(0) = C \text{ and } f(0) = 8 \Rightarrow C = 8, \text{ so } f(x) = x - 3x^2 + 8.$

24. $f'(x) = 8x^3 + 12x + 3 \Rightarrow f(x) = 2x^4 + 6x^2 + 3x + C. f(1) = 11 + C \text{ and } f(1) = 6 \Rightarrow$
 $11 + C = 6 \Rightarrow C = -5, \text{ so } f(x) = 2x^4 + 6x^2 + 3x - 5.$

25. $f'(x) = \sqrt{x}(6 + 5x) = 6x^{1/2} + 5x^{3/2} \Rightarrow f(x) = 4x^{3/2} + 2x^{5/2} + C.$

$$f(1) = 6 + C \text{ and } f(1) = 10 \Rightarrow C = 4, \text{ so } f(x) = 4x^{3/2} + 2x^{5/2} + 4.$$

26. $f'(x) = 2x - 3/x^4 = 2x - 3x^{-4} \Rightarrow f(x) = x^2 + x^{-3} + C$ because we're given that $x > 0$.

$$f(1) = 2 + C \text{ and } f(1) = 3 \Rightarrow C = 1, \text{ so } f(x) = x^2 + 1/x^3 + 1.$$

27. $f'(t) = 2 \cos t + \sec^2 t \Rightarrow f(t) = 2 \sin t + \tan t + C$ because $-\pi/2 < t < \pi/2$.

$$f(\frac{\pi}{3}) = 2(\sqrt{3}/2) + \sqrt{3} + C = 2\sqrt{3} + C \text{ and } f(\frac{\pi}{3}) = 4 \Rightarrow C = 4 - 2\sqrt{3}, \text{ so}$$

$$f(t) = 2 \sin t + \tan t + 4 - 2\sqrt{3}.$$

28. $f'(x) = 3x^{-2} \Rightarrow f(x) = \begin{cases} -3/x + C_1 & \text{if } x > 0 \\ -3/x + C_2 & \text{if } x < 0 \end{cases} \quad f(1) = -3 + C_1 = 0 \Rightarrow C_1 = 3,$

$$f(-1) = 3 + C_2 = 0 \Rightarrow C_2 = -3. \text{ So } f(x) = \begin{cases} -3/x + 3 & \text{if } x > 0 \\ -3/x - 3 & \text{if } x < 0 \end{cases}$$

29. $f''(x) = 24x^2 + 2x + 10 \Rightarrow f'(x) = 8x^3 + x^2 + 10x + C. f'(1) = 8 + 1 + 10 + C \text{ and } f'(1) = -3 \Rightarrow$
 $19 + C = -3 \Rightarrow C = -22, \text{ so } f'(x) = 8x^3 + x^2 + 10x - 22 \text{ and hence,}$

$$f(x) = 2x^4 + \frac{1}{3}x^3 + 5x^2 - 22x + D. f(1) = 2 + \frac{1}{3} + 5 - 22 + D \text{ and } f(1) = 5 \Rightarrow D = 22 - \frac{7}{3} = \frac{59}{3}.$$

$$\text{so } f(x) = 2x^4 + \frac{1}{3}x^3 + 5x^2 - 22x + \frac{59}{3}.$$

30. $f''(x) = 4 - 6x - 40x^3 \Rightarrow f'(x) = 4x - 3x^2 - 10x^4 + C$. $f'(0) = C$ and $f'(0) = 1 \Rightarrow C = 1$, so $f'(x) = 4x - 3x^2 - 10x^4 + 1$ and hence, $f(x) = 2x^2 - x^3 - 2x^5 + x + D$. $f(0) = D$ and $f(0) = 2 \Rightarrow D = 2$, so $f(x) = 2x^2 - x^3 - 2x^5 + x + 2$.
31. $f''(\theta) = \sin \theta + \cos \theta \Rightarrow f'(\theta) = -\cos \theta + \sin \theta + C$. $f'(0) = -1 + C$ and $f'(0) = 4 \Rightarrow C = 5$, so $f'(\theta) = -\cos \theta + \sin \theta + 5$ and hence, $f(\theta) = -\sin \theta - \cos \theta + 5\theta + D$. $f(0) = -1 + D$ and $f(0) = 3 \Rightarrow D = 4$, so $f(\theta) = -\sin \theta - \cos \theta + 5\theta + 4$.
32. $f''(t) = 3/\sqrt{t} = 3t^{-1/2} \Rightarrow f'(t) = 6t^{1/2} + C$. $f'(4) = 12 + C$ and $f'(4) = 7 \Rightarrow C = -5$, so $f'(t) = 6t^{1/2} - 5$ and hence, $f(t) = 4t^{3/2} - 5t + D$. $f(4) = 32 - 20 + D$ and $f(4) = 20 \Rightarrow D = 8$, so $f(t) = 4t^{3/2} - 5t + 8$.
33. $f''(x) = 2 - 12x \Rightarrow f'(x) = 2x - 6x^2 + C \Rightarrow f(x) = x^2 - 2x^3 + Cx + D$. $f(0) = D$ and $f(0) = 9 \Rightarrow D = 9$. $f(2) = 4 - 16 + 2C + 9 = 2C - 3$ and $f(2) = 15 \Rightarrow 2C = 18 \Rightarrow C = 9$, so $f(x) = x^2 - 2x^3 + 9x + 9$.
34. $f''(x) = 20x^3 + 12x^2 + 4 \Rightarrow f'(x) = 5x^4 + 4x^3 + 4x + C \Rightarrow f(x) = x^5 + x^4 + 2x^2 + Cx + D$. $f(0) = D$ and $f(0) = 8 \Rightarrow D = 8$. $f(1) = 1 + 1 + 2 + C + 8 = C + 12$ and $f(1) = 5 \Rightarrow C = -7$, so $f(x) = x^5 + x^4 + 2x^2 - 7x + 8$.
35. $f''(x) = 2 + \cos x \Rightarrow f'(x) = 2x + \sin x + C \Rightarrow f(x) = x^2 - \cos x + Cx + D$. $f(0) = -1 + D$ and $f(0) = -1 \Rightarrow D = 0$. $f(\frac{\pi}{2}) = \pi^2/4 + (\frac{\pi}{2})C$ and $f(\frac{\pi}{2}) = 0 \Rightarrow (\frac{\pi}{2})C = -\pi^2/4 \Rightarrow C = -\frac{\pi}{2}$, so $f(x) = x^2 - \cos x - (\frac{\pi}{2})x$.
36. $f'''(x) = \sin x \Rightarrow f''(x) = -\cos x + C \Rightarrow 1 = f''(0) = -1 + C \Rightarrow C = 2$, so $f''(x) = -\cos x + 2 \Rightarrow f'(x) = -\sin x + 2x + D \Rightarrow 1 = f'(0) = D \Rightarrow f'(x) = -\sin x + 2x + 1 \Rightarrow f(x) = \cos x + x^2 + x + E \Rightarrow 1 = f(0) = 1 + E \Rightarrow E = 0$, so $f(x) = \cos x + x^2 + x$.
37. Given $f'(x) = 2x + 1$, we have $f(x) = x^2 + x + C$. Since f passes through $(1, 6)$, $f(1) = 6 \Rightarrow 1^2 + 1 + C = 6 \Rightarrow C = 4$. Therefore, $f(x) = x^2 + x + 4$ and $f(2) = 2^2 + 2 + 4 = 10$.
38. $f'(x) = x^3 \Rightarrow f(x) = \frac{1}{4}x^4 + C$. $x + y = 0 \Rightarrow y = -x \Rightarrow m = -1$. Now $m = f'(x) \Rightarrow -1 = x^3 \Rightarrow x = -1 \Rightarrow y = 1$ (from the equation of the tangent line), so $(-1, 1)$ is a point on the graph of f . From f , $1 = \frac{1}{4}(-1)^4 + C \Rightarrow C = \frac{3}{4}$. Therefore, the function is $f(x) = \frac{1}{4}x^4 + \frac{3}{4}$.
39. b is the antiderivative of f . For small x , f is negative, so the graph of its antiderivative must be decreasing. But both a and c are increasing for small x , so only b can be f 's antiderivative. Also, f is positive where b is increasing, which supports our conclusion.
40. We know right away that c cannot be f 's antiderivative, since the slope of c is not zero at the x -value where $f = 0$. Now f is positive when a is increasing and negative when a is decreasing, so a is the antiderivative of f .
41. The graph of F will have a minimum at 0 and a maximum at 2, since $f = F'$ goes from negative to positive at $x = 0$, and from positive to negative at $x = 2$.
42. The position function is the antiderivative of the velocity function, so its graph has to be horizontal where the velocity function is equal to 0.

43.

$$f'(x) = \begin{cases} 2 & \text{if } 0 \leq x < 1 \\ 1 & \text{if } 1 < x < 2 \\ -1 & \text{if } 2 < x \leq 3 \end{cases} \Rightarrow f(x) = \begin{cases} 2x + C & \text{if } 0 \leq x < 1 \\ x + D & \text{if } 1 < x < 2 \\ -x + E & \text{if } 2 < x \leq 3 \end{cases}$$

$f(0) = -1 \Rightarrow 2(0) + C = -1 \Rightarrow C = -1$. Starting at the point $(0, -1)$ and moving to the right on a line with slope 2 gets us to the point $(1, 1)$. The slope for $1 < x < 2$ is 1, so we get to the point $(2, 2)$. Here we have used the fact that f is continuous. We can include the point $x = 1$ on

either the first or the second part of f . The line connecting $(1, 1)$ to $(2, 2)$ is $y = x$, so $D = 0$. The slope for $2 < x \leq 3$ is -1 , so we get to $(3, 1)$. $f(3) = 1 \Rightarrow -3 + E = 1 \Rightarrow E = 4$. Thus,

$$f(x) = \begin{cases} 2x - 1 & \text{if } 0 \leq x \leq 1 \\ x & \text{if } 1 < x < 2 \\ -x + 4 & \text{if } 2 \leq x \leq 3 \end{cases}$$

Note that $f'(x)$ does not exist at $x = 1$ or at $x = 2$.

44. (a)

(b) Since $F(0) = 1$, we can start our graph at $(0, 1)$. f has a minimum at about $x = 0.5$, so its derivative is zero there. f is decreasing on $(0, 0.5)$, so its derivative is negative and hence, F is CD on $(0, 0.5)$ and has an IP at $x \approx 0.5$. On $(0.5, 2.2)$, f is negative and increasing (f' is positive), so F is decreasing and CU. On $(2.2, \infty)$, f is positive and increasing, so F is increasing and CU.

(c) $f(x) = 2x - 3\sqrt{x} \Rightarrow$
 $F(x) = x^2 - 3 \cdot \frac{2}{3}x^{3/2} + C$. $F(0) = C$ and
 $F(0) = 1 \Rightarrow C = 1$, so
 $F(x) = x^2 - 2x^{3/2} + 1$.

(d)

45. $f(x) = \sin(x^2)$, $0 \leq x \leq 4$

46. $f(x) = 1/(x^4 + 1)$

47.

48.

49.

x	$f(x)$
0	1
0.5	0.959
1.0	0.841
1.5	0.665
2.0	0.455
2.5	0.239
3.0	0.047

x	$f(x)$
3.5	-0.100
4.0	-0.189
4.5	-0.217
5.0	-0.192
5.5	-0.128
6.0	-0.047

We compute slopes [values of $f(x) = (\sin x)/x$ for

$0 < x < 2\pi$] as in the table [$\lim_{x \rightarrow 0^+} f(x) = 1$] and draw a direction field as in Example 6. Then we use the direction

field to graph F starting at $(0, 0)$.

50.

x	$f(x)$
0	0
± 0.2	0.041
± 0.4	0.169
± 0.6	0.410
± 0.8	0.824
± 1.0	1.557
± 1.2	3.087
± 1.4	8.117
± 1.5	21.152

We compute slopes [values of $f(x) = x \tan x$ for $-\pi/2 < x < \pi/2$] as in the table and draw a direction field as in Example 6. Then we use the direction field to graph F starting at $(0, 0)$ and extending in both directions. Note that if f is an even function, then the antiderivative F that passes through the origin is an odd function.

51.

Remember that the given table values of f are the slopes of F at any x . For example, at $x = 1.4$, the slope of F is $f(1.4) = 0$.

52. (a)

(b) The general antiderivative of $f(x) = x^{-2}$ is

$$F(x) = \begin{cases} -1/x + C_1 & \text{if } x < 0 \\ -1/x + C_2 & \text{if } x > 0 \end{cases} \quad \text{since } f(x) \text{ is not defined at } x = 0.$$

The graph of the general antiderivatives of $f(x)$ looks like the graph in part (a), as expected.

53. $v(t) = s'(t) = \sin t - \cos t \Rightarrow s(t) = -\cos t - \sin t + C$. $s(0) = -1 + C$ and $s(0) = 0 \Rightarrow C = 1$, so $s(t) = -\cos t - \sin t + 1$.

54. $v(t) = s'(t) = 1.5\sqrt{t} \Rightarrow s(t) = t^{3/2} + C$. $s(4) = 8 + C$ and $s(4) = 10 \Rightarrow C = 2$, so $s(t) = t^{3/2} + 2$.

55. $a(t) = v'(t) = t - 2 \Rightarrow v(t) = \frac{1}{2}t^2 - 2t + C$. $v(0) = C$ and $v(0) = 3 \Rightarrow C = 3$, so $v(t) = \frac{1}{2}t^2 - 2t + 3$ and $s(t) = \frac{1}{6}t^3 - t^2 + 3t + D$. $s(0) = D$ and $s(0) = 1 \Rightarrow D = 1$, and $s(t) = \frac{1}{6}t^3 - t^2 + 3t + 1$.

56. $a(t) = v'(t) = \cos t + \sin t \Rightarrow v(t) = \sin t - \cos t + C \Rightarrow 5 = v(0) = -1 + C \Rightarrow C = 6$, so $v(t) = \sin t - \cos t + 6 \Rightarrow s(t) = -\cos t - \sin t + 6t + D \Rightarrow 0 = s(0) = -1 + D \Rightarrow D = 1$, so $s(t) = -\cos t - \sin t + 6t + 1$.

57. $a(t) = v'(t) = 10 \sin t + 3 \cos t \Rightarrow v(t) = -10 \cos t + 3 \sin t + C \Rightarrow s(t) = -10 \sin t - 3 \cos t + Ct + D$. $s(0) = -3 + D = 0$ and $s(2\pi) = -3 + 2\pi C + D = 12 \Rightarrow D = 3$ and $C = \frac{6}{\pi}$. Thus, $s(t) = -10 \sin t - 3 \cos t + \frac{6}{\pi}t + 3$.

58. $a(t) = v'(t) = 10 + 3t - 3t^2 \Rightarrow v(t) = 10t + \frac{3}{2}t^2 - t^3 + C \Rightarrow s(t) = 5t^2 + \frac{1}{2}t^3 - \frac{1}{4}t^4 + Ct + D \Rightarrow$
 $0 = s(0) = D$ and $10 = s(2) = 20 + 4 - 4 + 2C \Rightarrow C = -5$, so $s(t) = -5t + 5t^2 + \frac{1}{2}t^3 - \frac{1}{4}t^4$.
59. (a) We first observe that since the stone is dropped 450 m above the ground, $v(0) = 0$ and $s(0) = 450$.
 $v'(t) = a(t) = -9.8 \Rightarrow v(t) = -9.8t + C$. Now $v(0) = 0 \Rightarrow C = 0$, so $v(t) = -9.8t \Rightarrow$
 $s(t) = -4.9t^2 + D$. Last, $s(0) = 450 \Rightarrow D = 450 \Rightarrow s(t) = 450 - 4.9t^2$.
- (b) The stone reaches the ground when $s(t) = 0$. $450 - 4.9t^2 = 0 \Rightarrow t^2 = 450/4.9 \Rightarrow$
 $t_1 = \sqrt{450/4.9} \approx 9.58$ s.
- (c) The velocity with which the stone strikes the ground is $v(t_1) = -9.8\sqrt{450/4.9} \approx -93.9$ m/s.
- (d) This is just reworking parts (a) and (b) with $v(0) = -5$. Using $v(t) = -9.8t + C$, $v(0) = -5 \Rightarrow$
 $0 + C = -5 \Rightarrow v(t) = -9.8t - 5$. So $s(t) = -4.9t^2 - 5t + D$ and $s(0) = 450 \Rightarrow D = 450 \Rightarrow$
 $s(t) = -4.9t^2 - 5t + 450$. Solving $s(t) = 0$ by using the quadratic formula gives us
 $t = (5 \pm \sqrt{8845})/(-9.8) \Rightarrow t_1 \approx 9.09$ s.
60. $v'(t) = a(t) = a \Rightarrow v(t) = at + C$ and $v_0 = v(0) = C \Rightarrow v(t) = at + v_0 \Rightarrow$
 $s(t) = \frac{1}{2}at^2 + v_0t + D \Rightarrow s_0 = s(0) = D \Rightarrow s(t) = \frac{1}{2}at^2 + v_0t + s_0$
61. By Exercise 60 with $a = -9.8$, $s(t) = -4.9t^2 + v_0t + s_0$ and $v(t) = s'(t) = -9.8t + v_0$. So
 $[v(t)]^2 = (-9.8t + v_0)^2 = (9.8)^2 t^2 - 19.6v_0t + v_0^2 = v_0^2 + 96.04t^2 - 19.6v_0t = v_0^2 - 19.6(-4.9t^2 + v_0t)$.
 But $-4.9t^2 + v_0t$ is just $s(t)$ without the s_0 term; that is, $s(t) - s_0$. Thus, $[v(t)]^2 = v_0^2 - 19.6[s(t) - s_0]$.
62. For the first ball, $s_1(t) = -16t^2 + 48t + 432$ from Example 8. For the second ball, $a(t) = -32 \Rightarrow$
 $v(t) = -32t + C$, but $v(1) = -32(1) + C = 24 \Rightarrow C = 56$, so $v(t) = -32t + 56 \Rightarrow$
 $s(t) = -16t^2 + 56t + D$, but $s(1) = -16(1)^2 + 56(1) + D = 432 \Rightarrow D = 392$, and
 $s_2(t) = -16t^2 + 56t + 392$. The balls pass each other when $s_1(t) = s_2(t) \Rightarrow$
 $-16t^2 + 48t + 432 = -16t^2 + 56t + 392 \Leftrightarrow 8t = 40 \Leftrightarrow t = 5$ s.
Another solution: From Exercise 60, we have $s_1(t) = -16t^2 + 48t + 432$ and $s_2(t) = -16t^2 + 24t + 432$.
 We now want to solve $s_1(t) = s_2(t - 1) \Rightarrow -16t^2 + 48t + 432 = -16(t - 1)^2 + 24(t - 1) + 432 \Rightarrow$
 $48t = 32t - 16 + 24t - 24 \Rightarrow 40 = 8t \Rightarrow t = 5$ s.
63. Using Exercise 60 with $a = -32$, $v_0 = 0$, and $s_0 = h$ (the height of the cliff), we know that the height at time t is
 $s(t) = -16t^2 + h$. $v(t) = s'(t) = -32t$ and $v(t) = -120 \Rightarrow -32t = -120 \Rightarrow t = 3.75$, so
 $0 = s(3.75) = -16(3.75)^2 + h \Rightarrow h = 16(3.75)^2 = 225$ ft.
64. (a) $EIy'' = mg(L - x) + \frac{1}{2}\rho g(L - x)^2 \Rightarrow EIy' = -\frac{1}{2}mg(L - x)^2 - \frac{1}{6}\rho g(L - x)^3 + C \Rightarrow$
 $EIy = \frac{1}{6}mg(L - x)^3 + \frac{1}{24}\rho g(L - x)^4 + Cx + D$. Since the left end of the board is fixed, we must have
 $y = y' = 0$ when $x = 0$. Thus, $0 = -\frac{1}{2}mgL^2 - \frac{1}{6}\rho gL^3 + C$ and $0 = \frac{1}{6}mgL^3 + \frac{1}{24}\rho gL^4 + D$. It follows that

$$EIy = \frac{1}{6}mg(L-x)^3 + \frac{1}{24}\rho g(L-x)^4 + \left(\frac{1}{2}mgL^2 + \frac{1}{6}\rho gL^3\right)x - \left(\frac{1}{6}mgL^3 + \frac{1}{24}\rho gL^4\right) \text{ and}$$

$$f(x) = y = \frac{1}{EI} \left[\frac{1}{6}mg(L-x)^3 + \frac{1}{24}\rho g(L-x)^4 + \left(\frac{1}{2}mgL^2 + \frac{1}{6}\rho gL^3\right)x - \left(\frac{1}{6}mgL^3 + \frac{1}{24}\rho gL^4\right) \right]$$

- (b) $f(L) < 0$, so the end of the board is a *distance* approximately $-f(L)$ below the horizontal. From our result in (a), we calculate

$$\begin{aligned} -f(L) &= \frac{-1}{EI} \left[\frac{1}{2}mgL^3 + \frac{1}{6}\rho gL^4 - \frac{1}{6}mgL^3 - \frac{1}{24}\rho gL^4 \right] \\ &= \frac{-1}{EI} \left(\frac{1}{3}mgL^3 + \frac{1}{8}\rho gL^4 \right) = -\frac{gL^3}{EI} \left(\frac{m}{3} + \frac{\rho L}{8} \right) \end{aligned}$$

Note: This is positive because g is negative.

65. Marginal cost $= 1.92 - 0.002x = C'(x) \Rightarrow C(x) = 1.92x - 0.001x^2 + K$. But

$$C(1) = 1.92 - 0.001 + K = 562 \Rightarrow K = 560.081. \text{ Therefore, } C(x) = 1.92x - 0.001x^2 + 560.081 \Rightarrow$$

$$C(100) = 742.081, \text{ so the cost of producing 100 items is } \$742.08.$$

66. Let the mass, measured from one end, be $m(x)$. Then $m(0) = 0$ and $\rho = \frac{dm}{dx} = x^{-1/2} \Rightarrow m(x) = 2x^{1/2} + C$

$$\text{and } m(0) = C = 0, \text{ so } m(x) = 2\sqrt{x}. \text{ Thus, the mass of the 100-centimeter rod is } m(100) = 2\sqrt{100} = 20 \text{ g.}$$

67. Taking the upward direction to be positive we have that for $0 \leq t \leq 10$ (using the subscript 1 to refer to

$$0 \leq t \leq 10), a_1(t) = -(9 - 0.9t) = v_1'(t) \Rightarrow v_1(t) = -9t + 0.45t^2 + v_0, \text{ but } v_1(0) = v_0 = -10 \Rightarrow$$

$$v_1(t) = -9t + 0.45t^2 - 10 = s_1'(t) \Rightarrow s_1(t) = -\frac{9}{2}t^2 + 0.15t^3 - 10t + s_0. \text{ But } s_1(0) = 500 = s_0 \Rightarrow$$

$$s_1(t) = -\frac{9}{2}t^2 + 0.15t^3 - 10t + 500. \quad s_1(10) = -450 + 150 - 100 + 500 = 100, \text{ so it takes more}$$

than 10 seconds for the raindrop to fall. Now for $t > 10$, $a(t) = 0 = v'(t) \Rightarrow$

$$v(t) = \text{constant} = v_1(10) = -9(10) + 0.45(10)^2 - 10 = -55 \Rightarrow v(t) = -55. \text{ At 55 ft/s, it will take}$$

$$100/55 \approx 1.8 \text{ s to fall the last 100 ft. Hence, the total time is } 10 + \frac{100}{55} = \frac{130}{11} \approx 11.8 \text{ s.}$$

68. $v'(t) = a(t) = -22$. The initial velocity is 50 mi/h $= \frac{50 \cdot 5280}{3600} = \frac{220}{3}$ ft/s, so $v(t) = -22t + \frac{220}{3}$. The car stops

$$\text{when } v(t) = 0 \Leftrightarrow t = \frac{220}{3 \cdot 22} = \frac{10}{3}. \text{ Since } s(t) = -11t^2 + \frac{220}{3}t, \text{ the distance covered is}$$

$$s\left(\frac{10}{3}\right) = -11\left(\frac{10}{3}\right)^2 + \frac{220}{3} \cdot \frac{10}{3} = \frac{1100}{9} = 122.\bar{2} \text{ ft.}$$

69. $a(t) = k$, the initial velocity is 30 mi/h $= 30 \cdot \frac{5280}{3600} = 44$ ft/s, and the final velocity (after 5 seconds) is

$$50 \text{ mi/h} = 50 \cdot \frac{5280}{3600} = \frac{220}{3} \text{ ft/s. So } v(t) = kt + C \text{ and } v(0) = 44 \Rightarrow C = 44. \text{ Thus, } v(t) = kt + 44 \Rightarrow$$

$$v(5) = 5k + 44. \text{ But } v(5) = \frac{220}{3}, \text{ so } 5k + 44 = \frac{220}{3} \Rightarrow 5k = \frac{88}{3} \Rightarrow k = \frac{88}{15} \approx 5.87 \text{ ft/s}^2.$$

70. $a(t) = -16 \Rightarrow v(t) = -16t + v_0$ where v_0 is the car's speed (in ft/s) when the brakes were applied. The car

$$\text{stops when } -16t + v_0 = 0 \Leftrightarrow t = \frac{1}{16}v_0. \text{ Now } s(t) = \frac{1}{2}(-16)t^2 + v_0t = -8t^2 + v_0t. \text{ The car travels 200 ft in}$$

$$\text{the time that it takes to stop, so } s\left(\frac{1}{16}v_0\right) = 200 \Rightarrow 200 = -8\left(\frac{1}{16}v_0\right)^2 + v_0\left(\frac{1}{16}v_0\right) = \frac{1}{32}v_0^2 \Rightarrow$$

$$v_0^2 = 32 \cdot 200 = 6400 \Rightarrow v_0 = 80 \text{ ft/s } (54.54 \text{ mi/h}).$$

71. Let the acceleration be $a(t) = k \text{ km/h}^2$. We have $v(0) = 100 \text{ km/h}$ and we can take the initial position $s(0)$ to be 0. We want the time t_f for which $v(t) = 0$ to satisfy $s(t) < 0.08 \text{ km}$. In general, $v'(t) = a(t) = k$, so $v(t) = kt + C$, where $C = v(0) = 100$. Now $s'(t) = v(t) = kt + 100$, so $s(t) = \frac{1}{2}kt^2 + 100t + D$, where $D = s(0) = 0$. Thus, $s(t) = \frac{1}{2}kt^2 + 100t$. Since $v(t_f) = 0$, we have $kt_f + 100 = 0$ or $t_f = -100/k$, so
- $$s(t_f) = \frac{1}{2}k \left(-\frac{100}{k}\right)^2 + 100 \left(-\frac{100}{k}\right) = 10,000 \left(\frac{1}{2k} - \frac{1}{k}\right) = -\frac{5,000}{k}.$$
- The condition $s(t_f)$ must satisfy is
- $$-\frac{5,000}{k} < 0.08 \Rightarrow -\frac{5,000}{0.08} > k \quad [k \text{ is negative}] \Rightarrow k < -62,500 \text{ km/h}^2, \text{ or equivalently,}$$
- $$k < -\frac{3125}{648} \approx -4.82 \text{ m/s}^2.$$

72. (a) For $0 \leq t \leq 3$ we have $a(t) = 60t \Rightarrow v(t) = 30t^2 + C \Rightarrow v(0) = 0 = C \Rightarrow v(t) = 30t^2$, so $s(t) = 10t^3 + C \Rightarrow s(0) = 0 = C \Rightarrow s(t) = 10t^3$. Note that $v(3) = 270$ and $s(3) = 270$. For $3 < t \leq 17$: $a(t) = -g = -32 \text{ ft/s}^2 \Rightarrow v(t) = -32(t-3) + C \Rightarrow v(3) = 270 = C \Rightarrow v(t) = -32(t-3) + 270 \Rightarrow s(t) = -16(t-3)^2 + 270(t-3) + C \Rightarrow s(3) = 270 = C \Rightarrow s(t) = -16(t-3)^2 + 270(t-3) + 270$. Note that $v(17) = -178$ and $s(17) = 914$. For $17 < t \leq 22$: The velocity increases linearly from -178 ft/s to -18 ft/s during this period, so $\frac{\Delta v}{\Delta t} = \frac{-18 - (-178)}{22 - 17} = \frac{160}{5} = 32$. Thus, $v(t) = 32(t-17) - 178 \Rightarrow s(t) = 16(t-17)^2 - 178(t-17) + 914$ and $s(22) = 424 \text{ ft}$. For $t > 22$: $v(t) = -18 \Rightarrow s(t) = -18(t-22) + C$. But $s(22) = 424 = C \Rightarrow s(t) = -18(t-22) + 424$.

Therefore, until the rocket lands, we have

$$v(t) = \begin{cases} 30t^2 & \text{if } 0 \leq t \leq 3 \\ -32(t-3) + 270 & \text{if } 3 < t \leq 17 \\ 32(t-17) - 178 & \text{if } 17 < t \leq 22 \\ -18 & \text{if } t > 22 \end{cases}$$

and

$$s(t) = \begin{cases} 10t^3 & \text{if } 0 \leq t \leq 3 \\ -16(t-3)^2 + 270(t-3) + 270 & \text{if } 3 < t \leq 17 \\ 16(t-17)^2 - 178(t-17) + 914 & \text{if } 17 < t \leq 22 \\ -18(t-22) + 424 & \text{if } t > 22 \end{cases}$$

- (b) To find the maximum height, set $v(t)$ on $3 < t \leq 17$ equal to 0. $-32(t-3) + 270 = 0 \Rightarrow t_1 = 11.4375 \text{ s}$ and the maximum height is $s(t_1) = -16(t_1-3)^2 + 270(t_1-3) + 270 = 1409.0625 \text{ ft}$.
- (c) To find the time to land, set $s(t) = -18(t-22) + 424 = 0$. Then $t-22 = \frac{424}{18} = 23.\bar{5}$, so $t \approx 45.6 \text{ s}$.

73. (a) First note that $90 \text{ mi/h} = 90 \times \frac{5280}{3600} \text{ ft/s} = 132 \text{ ft/s}$. Then $a(t) = 4 \text{ ft/s}^2 \Rightarrow v(t) = 4t + C$, but $v(0) = 0 \Rightarrow C = 0$. Now $4t = 132$ when $t = \frac{132}{4} = 33 \text{ s}$, so it takes 33 s to reach 132 ft/s. Therefore, taking $s(0) = 0$, we have $s(t) = 2t^2$, $0 \leq t \leq 33$. So $s(33) = 2178 \text{ ft}$. 15 minutes = $15(60) = 900 \text{ s}$, so for $33 < t \leq 933$ we have $v(t) = 132 \text{ ft/s} \Rightarrow s(933) = 132(900) + 2178 = 120,978 \text{ ft} = 22.9125 \text{ mi}$.
- (b) As in part (a), the train accelerates for 33 s and travels 2178 ft while doing so. Similarly, it decelerates for 33 s and travels 2178 ft at the end of its trip. During the remaining $900 - 66 = 834 \text{ s}$ it travels at 132 ft/s, so the distance traveled is $132 \cdot 834 = 110,088 \text{ ft}$. Thus, the total distance is $2178 + 110,088 + 2178 = 114,444 \text{ ft} = 21.675 \text{ mi}$.
- (c) $45 \text{ mi} = 45(5280) = 237,600 \text{ ft}$. Subtract $2(2178)$ to take care of the speeding up and slowing down, and we have 233,244 ft at 132 ft/s for a trip of $233,244/132 = 1767 \text{ s}$ at 90 mi/h. The total time is $1767 + 2(33) = 1833 \text{ s} = 30 \text{ min } 33 \text{ s} = 30.55 \text{ min}$.
- (d) $37.5(60) = 2250 \text{ s}$. $2250 - 2(33) = 2184 \text{ s}$ at maximum speed. $2184(132) + 2(2178) = 292,644 \text{ total feet}$ or $292,644/5280 = 55.425 \text{ mi}$.

4 Review

CONCEPT CHECK

- A function f has an **absolute maximum** at $x = c$ if $f(c)$ is the largest function value on the entire domain of f , whereas f has a **local maximum** at c if $f(c)$ is the largest function value when x is near c . See Figure 4 in Section 4.1.
- (a) See Theorem 4.1.3.
(b) See the Closed Interval Method before Example 8 in Section 4.1.
- (a) See Theorem 4.1.4.
(b) See Definition 4.1.6.
- (a) See Rolle's Theorem at the beginning of Section 4.2.
(b) See the Mean Value Theorem in Section 4.2. Geometric interpretation—there is some point P on the graph of a function f [on the interval (a, b)] where the tangent line is parallel to the secant line that connects $(a, f(a))$ and $(b, f(b))$.
- (a) See the I/D Test before Example 1 in Section 4.3.
(b) See the Concavity Test before Example 4 in Section 4.3.
- (a) See the First Derivative Test after Example 1 in Section 4.3.
(b) See the Second Derivative Test before Example 6 in Section 4.3.
(c) See the note before Example 7 in Section 4.3.
- (a) See Definitions 4.4.1 and 4.4.5.
(b) See Definitions 4.4.2 and 4.4.6.
(c) See Definition 4.4.7.
(d) See Definition 4.4.3.
- Without calculus you could get misleading graphs that fail to show the most interesting features of a function. See the discussion following Figure 3 in Section 4.5 and the first paragraph in Section 4.6.

9. (a) See Figure 3 in Section 4.9.

$$(b) x_2 = x_1 - \frac{f(x_1)}{f'(x_1)}$$

$$(c) x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

(d) Newton's method is likely to fail or to work very slowly when $f'(x_1)$ is close to 0.

10. (a) See the definition at the beginning of Section 4.10.

(b) If F_1 and F_2 are both antiderivatives of f on an interval I , then they differ by a constant.

TRUE-FALSE QUIZ

- False. For example, take $f(x) = x^3$, then $f'(x) = 3x^2$ and $f'(0) = 0$, but $f(0) = 0$ is not a maximum or minimum; $(0, 0)$ is an inflection point.
- False. For example, $f(x) = |x|$ has an absolute minimum at 0, but $f'(0)$ does not exist.
- False. For example, $f(x) = x$ is continuous on $(0, 1)$ but attains neither a maximum nor a minimum value on $(0, 1)$. Don't confuse this with f being continuous on the *closed* interval $[a, b]$, which would make the statement true.
- True. By the Mean Value Theorem, $f'(c) = \frac{f(1) - f(-1)}{1 - (-1)} = \frac{0}{2} = 0$. Note that $|c| < 1 \Leftrightarrow c \in (-1, 1)$.
- True. This is an example of part (b) of the I/D Test.
- False. For example, the curve $y = f(x) = 1$ has no inflection points but $f''(c) = 0$ for all c .
- False. $f'(x) = g'(x) \Rightarrow f(x) = g(x) + C$. For example, if $f(x) = x + 2$ and $g(x) = x + 1$, then $f'(x) = g'(x) = 1$, but $f(x) \neq g(x)$.
- False. Assume there is a function f such that $f(1) = -2$ and $f(3) = 0$. Then by the Mean Value Theorem there exists a number $c \in (1, 3)$ such that $f'(c) = \frac{f(3) - f(1)}{3 - 1} = \frac{0 - (-2)}{2} = 1$. But $f'(x) > 1$ for all x , a contradiction.
- True. The graph of one such function is sketched.

- False. At any point $(a, f(a))$, we know that $f'(a) < 0$. So since the tangent line at $(a, f(a))$ is not horizontal, it must cross the x -axis—at $x = b$, say. But since $f''(x) > 0$ for all x , the graph of f must lie above all of its tangents; in particular, $f(b) > 0$. But this is a contradiction, since we are given that $f(x) < 0$ for all x .
- True. Let $x_1 < x_2$ where $x_1, x_2 \in I$. Then $f(x_1) < f(x_2)$ and $g(x_1) < g(x_2)$ (since f and g are increasing on I), so $(f + g)(x_1) = f(x_1) + g(x_1) < f(x_2) + g(x_2) = (f + g)(x_2)$.
- False. $f(x) = x$ and $g(x) = 2x$ are both increasing on $(0, 1)$, but $f(x) - g(x) = -x$ is not increasing on $(0, 1)$.

13. False. Take $f(x) = x$ and $g(x) = x - 1$. Then both f and g are increasing on $(0, 1)$. But $f(x)g(x) = x(x - 1)$ is not increasing on $(0, 1)$.
14. True. Let $x_1 < x_2$ where $x_1, x_2 \in I$. Then $0 < f(x_1) < f(x_2)$ and $0 < g(x_1) < g(x_2)$ (since f and g are both positive and increasing). Hence, $f(x_1)g(x_1) < f(x_2)g(x_1) < f(x_2)g(x_2)$. So fg is increasing on I .
15. True. Let $x_1, x_2 \in I$ and $x_1 < x_2$. Then $f(x_1) < f(x_2)$ (f is increasing) $\Rightarrow$
 $\frac{1}{f(x_1)} > \frac{1}{f(x_2)}$ (f is positive) $\Rightarrow g(x_1) > g(x_2) \Rightarrow g(x) = 1/f(x)$ is decreasing on I .
16. False. The most general antiderivative is $F(x) = -1/x + C_1$ for $x < 0$ and $F(x) = -1/x + C_2$ for $x > 0$ (see Example 1 in Section 4.10).
17. True. By the Mean Value Theorem, there exists a number c in $(0, 1)$ such that
 $f(1) - f(0) = f'(c)(1 - 0) = f'(c)$. Since $f'(c)$ is nonzero, $f(1) - f(0) \neq 0$, so $f(1) \neq f(0)$.

EXERCISES

1. $f(x) = 10 + 27x - x^3$, $0 \leq x \leq 4$. $f'(x) = 27 - 3x^2 = -3(x^2 - 9) = -3(x + 3)(x - 3) = 0$ only when $x = 3$ (since -3 is not in the domain). $f'(x) > 0$ for $x < 3$ and $f'(x) < 0$ for $x > 3$, so $f(3) = 64$ is a local maximum value. Checking the endpoints, we find $f(0) = 10$ and $f(4) = 54$. Thus, $f(0) = 10$ is the absolute minimum value and $f(3) = 64$ is the absolute maximum value.
2. $f(x) = x - \sqrt{x}$, $0 \leq x \leq 4$. $f'(x) = 1 - 1/(2\sqrt{x}) = 0 \Leftrightarrow 2\sqrt{x} = 1 \Rightarrow x = \frac{1}{4}$. $f'(x)$ does not exist $\Leftrightarrow x = 0$. $f'(x) < 0$ for $0 < x < \frac{1}{4}$ and $f'(x) > 0$ for $\frac{1}{4} < x < 4$, so $f(\frac{1}{4}) = -\frac{1}{4}$ is a local and absolute minimum value. $f(0) = 0$ and $f(4) = 2$, so $f(4) = 2$ is the absolute maximum value.
3. $f(x) = \frac{x}{x^2 + x + 1}$, $-2 \leq x \leq 0$. $f'(x) = \frac{(x^2 + x + 1)(1) - x(2x + 1)}{(x^2 + x + 1)^2} = \frac{1 - x^2}{(x^2 + x + 1)^2} = 0 \Leftrightarrow x = -1$ (since 1 is not in the domain). $f'(x) < 0$ for $-2 < x < -1$ and $f'(x) > 0$ for $-1 < x < 0$, so $f(-1) = -1$ is a local and absolute minimum value. $f(-2) = -\frac{2}{3}$ and $f(0) = 0$, so $f(0) = 0$ is an absolute maximum value.
4. $f(x) = (x^2 + 2x)^3$, $[-2, 1]$. $f'(x) = 3(x^2 + 2x)^2(2x + 2) = 6(x + 1)x^2(x + 2)^2$, so the only critical numbers in the interior of the domain are $x = -1, 0$. $f'(x) < 0$ for $-2 < x < -1$ and $f'(x) > 0$ for $-1 < x < 0$ and $0 < x < 1$, so f is decreasing on $(-2, -1)$ and increasing on $(-1, 1)$. Thus, $f(-1) = -1$ is a local minimum value. $f(-2) = 0$ and $f(1) = 27$, so the local minimum value is the absolute minimum value and $f(1) = 27$ is the absolute maximum value.
5. $f(x) = x + \sin 2x$, $[0, \pi]$. $f'(x) = 1 + 2\cos 2x = 0 \Leftrightarrow \cos 2x = -\frac{1}{2} \Leftrightarrow 2x = \frac{2\pi}{3}$ or $\frac{4\pi}{3} \Leftrightarrow x = \frac{\pi}{3}$ or $\frac{2\pi}{3}$. $f''(x) = -4\sin 2x$, so $f''(\frac{\pi}{3}) = -4\sin \frac{2\pi}{3} = -2\sqrt{3} < 0$ and $f''(\frac{2\pi}{3}) = -4\sin \frac{4\pi}{3} = 2\sqrt{3} > 0$, so $f(\frac{\pi}{3}) = \frac{\pi}{3} + \frac{\sqrt{3}}{2} \approx 1.91$ is a local maximum value and $f(\frac{2\pi}{3}) = \frac{2\pi}{3} - \frac{\sqrt{3}}{2} \approx 1.23$ is a local minimum value. Also $f(0) = 0$ and $f(\pi) = \pi$, so $f(0) = 0$ is the absolute minimum value and $f(\pi) = \pi$ is the absolute maximum value.
6. $f(x) = \sin x + \cos^2 x$, $[0, \pi]$. $f'(x) = \cos x - 2\cos x \sin x = \cos x(1 - 2\sin x)$, so $f'(x) = 0$ for x in $(0, \pi) \Leftrightarrow \cos x = 0$ or $\sin x = \frac{1}{2} \Leftrightarrow x = \frac{\pi}{6}, \frac{\pi}{2}$, or $\frac{5\pi}{6}$. $f'(x) = \cos x - \sin 2x \Rightarrow f''(x) = -\sin x - 2\cos 2x$, so $f''(\frac{\pi}{6}) = -\frac{1}{2} - 2(\frac{1}{2}) = -\frac{3}{2}$, $f''(\frac{\pi}{2}) = -1 - 2(-1) = 1$, and $f''(\frac{5\pi}{6}) = -\frac{1}{2} - 2(\frac{1}{2}) = -\frac{3}{2}$. Thus, $f(\frac{\pi}{6}) = \frac{5}{4}$ and $f(\frac{5\pi}{6}) = \frac{5}{4}$ are local maxima and $f(\frac{\pi}{2}) = 1$ is a local minimum. $f(0) = 1$ and $f(\pi) = 1$, so f has its absolute minimum value of 1 at $0, \frac{\pi}{2}$, and π . f attains its absolute maximum value of $\frac{5}{4}$ at $\frac{\pi}{6}$ and $\frac{5\pi}{6}$.

$$7. \lim_{x \rightarrow \infty} \frac{3x^4 + x - 5}{6x^4 - 2x^2 + 1} = \lim_{x \rightarrow \infty} \frac{3 + \frac{1}{x^3} - \frac{5}{x^4}}{6 - \frac{2}{x^2} + \frac{1}{x^4}} = \frac{3 + 0 + 0}{6 - 0 + 0} = \frac{1}{2}$$

$$8. \lim_{t \rightarrow \infty} \frac{t^3 - t + 2}{(2t - 1)(t^2 + t + 1)} = \lim_{t \rightarrow \infty} \frac{1 - 1/t^2 + 2/t^3}{(2 - 1/t)(1 + 1/t + 1/t^2)} = \frac{1}{2 \cdot 1} = \frac{1}{2}$$

$$9. \lim_{x \rightarrow -\infty} \frac{\sqrt{4x^2 + 1}}{3x - 1} = \lim_{x \rightarrow -\infty} \frac{\sqrt{4x^2 + 1}/\sqrt{x^2}}{(3x - 1)/\sqrt{x^2}} = \lim_{x \rightarrow -\infty} \frac{\sqrt{4 + 1/x^2}}{-3 + 1/x} \quad [\text{since } -x = |x| = \sqrt{x^2} \text{ for } x < 0]$$

$$= \frac{2}{-3 + 0} = -\frac{2}{3}$$

$$f(x) = -x + D. 1 = f(1) = -1 + D \Rightarrow D = 2, \text{ so}$$

$$f(x) = 2 - x. \text{ For } x > 3, f'(x) = 1, \text{ so } f(x) = x + E.$$

$$-1 = f(3) = 3 + E \Rightarrow E = -4, \text{ so } f(x) = x - 4. \text{ Since } f$$

$$\text{is even, its graph is symmetric about the } y\text{-axis.}$$

$$15. f \text{ is odd, } f'(x) < 0 \text{ for } 0 < x < 2, \quad f'(x) > 0 \text{ for } x > 2,$$

$$f''(x) > 0 \text{ for } 0 < x < 3, \quad f''(x) < 0 \text{ for } x > 3,$$

$$\lim_{x \rightarrow \infty} f(x) = -2$$

16. (a) Using the Test for Monotonic Functions we know that f is increasing on $(-2, 0)$ and $(4, \infty)$ because $f' > 0$ on $(-2, 0)$ and $(4, \infty)$, and that f is decreasing on $(-\infty, -2)$ and $(0, 4)$ because $f' < 0$ on $(-\infty, -2)$ and $(0, 4)$.
- (b) Using the First Derivative Test, we know that f has a local maximum at $x = 0$ because f' changes from positive to negative at $x = 0$, and that f has a local minimum at $x = 4$ because f' changes from negative to positive at $x = 4$.

17. $y = f(x) = 2 - 2x - x^3$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 2$.
The x -intercept (approximately 0.770917) can be found using Newton's Method. C. No symmetry D. No asymptote
E. $f'(x) = -2 - 3x^2 = -(3x^2 + 2) < 0$, so f is decreasing on $\mathbb{R}$.
F. No extreme value G. $f''(x) = -6x < 0$ on $(0, \infty)$ and $f''(x) > 0$ on $(-\infty, 0)$, so f is CD on $(0, \infty)$ and CU on $(-\infty, 0)$.
There is an IP at $(0, 2)$.

18. $y = f(x) = x^3 - 6x^2 - 15x + 4$ A. $D = \mathbb{R}$
B. y -intercept: $f(0) = 4$; x -intercepts: $f(x) = 0 \Rightarrow x \approx -2.09, 0.24, 7.85$ C. No symmetry D. No asymptote
E. $f'(x) = 3x^2 - 12x - 15 = 3(x^2 - 4x - 5) = 3(x + 1)(x - 5)$, so f is increasing on $(-\infty, -1)$, decreasing on $(-1, 5)$, and increasing on $(5, \infty)$. F. Local maximum value $f(-1) = 12$, local minimum value $f(5) = -96$. G. $f''(x) = 6x - 12 = 6(x - 2)$, so f is CD on $(-\infty, 2)$ and CU on $(2, \infty)$. There is an IP at $(2, -42)$.

19. $y = f(x) = x^4 - 3x^3 + 3x^2 - x = x(x - 1)^3$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$; x -intercepts: $f(x) = 0 \Leftrightarrow x = 0$ or $x = 1$ C. No symmetry D. f is a polynomial function and hence, it has no asymptote.
E. $f'(x) = 4x^3 - 9x^2 + 6x - 1$. Since the sum of the coefficients is 0, 1 is a root of f' , so $f'(x) = (x - 1)(4x^2 - 5x + 1) = (x - 1)^2(4x - 1)$. $f'(x) < 0 \Rightarrow x < \frac{1}{4}$, so f is decreasing on $(-\infty, \frac{1}{4})$ and f is increasing on $(\frac{1}{4}, \infty)$. F. $f'(x)$ does not change sign at $x = 1$, so there is not a local extremum there. $f(\frac{1}{4}) = -\frac{27}{256}$ is a local minimum value. G. $f''(x) = 12x^2 - 18x + 6 = 6(2x - 1)(x - 1)$.
 $f''(x) = 0 \Leftrightarrow x = \frac{1}{2}$ or 1 . $f''(x) < 0 \Leftrightarrow \frac{1}{2} < x < 1 \Rightarrow f$ is CD on $(\frac{1}{2}, 1)$ and CU on $(-\infty, \frac{1}{2})$ and $(1, \infty)$. There are inflection points at $(\frac{1}{2}, -\frac{1}{16})$ and $(1, 0)$.

20. $y = f(x) = \frac{1}{1-x^2} = \frac{1}{(1+x)(1-x)}$ A. $D = \{x \mid x \neq \pm 1\}$ B. y -intercept: $f(0) = 1$; no x -intercept

C. $f(-x) = f(x)$, so f is even and the graph of f is symmetric about the y -axis. D. Vertical asymptotes:

$x = \pm 1$. Horizontal asymptote: $y = 0$ E. $y' = \frac{2x}{(1-x^2)^2} = 0 \Leftrightarrow x = 0$, so f is decreasing on $(-\infty, -1)$

and $(-1, 0)$, and increasing on $(0, 1)$ and $(1, \infty)$.

F. Local minimum value $f(0) = 1$; no local maximum

G. $f''(x) = \frac{(1-x^2)^2 \cdot 2 - 2x \cdot 2(1-x^2)(-2x)}{(1-x^2)^4}$
 $= \frac{2(1-x^2) + 8x^2}{(1-x^2)^3} = \frac{6x^2 + 2}{(1-x^2)^3} < 0 \Leftrightarrow x^2 > 1,$

so f is CD on $(-\infty, -1)$ and $(1, \infty)$, and CU on $(-1, 1)$. No IP

H.

21. $y = f(x) = \frac{1}{x(x-3)^2}$ A. $D = \{x \mid x \neq 0, 3\} = (-\infty, 0) \cup (0, 3) \cup (3, \infty)$ B. No intercepts.

C. No symmetry. D. $\lim_{x \rightarrow \pm\infty} \frac{1}{x(x-3)^2} = 0$, so $y = 0$ is a HA. $\lim_{x \rightarrow 0^+} \frac{1}{x(x-3)^2} = \infty,$

$\lim_{x \rightarrow 0^-} \frac{1}{x(x-3)^2} = -\infty, \lim_{x \rightarrow 3^-} \frac{1}{x(x-3)^2} = \infty, \lim_{x \rightarrow 3^+} \frac{1}{x(x-3)^2} = -\infty,$ so $x = 0$ and $x = 3$ are VA.

E. $f'(x) = -\frac{(x-3)^2 + 2x(x-3)}{x^2(x-3)^4} = \frac{3(1-x)}{x^2(x-3)^3} \Rightarrow$

$f'(x) > 0 \Leftrightarrow 1 < x < 3$, so f is increasing on $(1, 3)$ and decreasing on $(-\infty, 0)$, $(0, 1)$, and $(3, \infty)$. F. Local minimum value $f(1) = \frac{1}{4}$

G. $f''(x) = \frac{6(2x^2 - 4x + 3)}{x^3(x-3)^4}$. Note that $2x^2 - 4x + 3 > 0$ for all x

since it has negative discriminant. So $f''(x) > 0 \Leftrightarrow x > 0 \Rightarrow f$ is

CU on $(0, 3)$ and $(3, \infty)$ and CD on $(-\infty, 0)$. No IP

H.

22. $y = f(x) = \frac{1}{x} + \frac{1}{x+1} = \frac{2x+1}{x(x+1)}$ A. $D = \{x \mid x \neq 0, -1\}$ B. No y -intercept, x -intercept $= -\frac{1}{2}$

C. No symmetry D. $\lim_{x \rightarrow \pm\infty} f(x) = 0$, so $y = 0$ is a HA. $\lim_{x \rightarrow 0^+} \frac{2x+1}{x(x+1)} = \infty, \lim_{x \rightarrow 0^-} \frac{2x+1}{x(x+1)} = -\infty,$

$\lim_{x \rightarrow -1^+} \frac{2x+1}{x(x+1)} = \infty, \lim_{x \rightarrow -1^-} \frac{2x+1}{x(x+1)} = -\infty$, so $x = 0, x = -1$ are VA.

E. $f'(x) = -\frac{1}{x^2} - \frac{1}{(x+1)^2} < 0$, so f is decreasing on $(-\infty, -1)$,

$(-1, 0)$ and $(0, \infty)$. F. No extreme values

G. $f''(x) = \frac{2}{x^3} + \frac{2}{(x+1)^3} = \frac{2(2x+1)(x^2+x+1)}{x^3(x+1)^3}$.

$f''(x) > 0 \Leftrightarrow x > 0$ or $-1 < x < -\frac{1}{2}$, so f is CU on $(0, \infty)$ and $(-1, -\frac{1}{2})$ and CD on $(-\infty, -1)$ and $(-\frac{1}{2}, 0)$. IP at $(-\frac{1}{2}, 0)$

H.

23. $y = f(x) = \frac{x^2}{x+8} = x - 8 + \frac{64}{x+8}$ A. $D = \{x \mid x \neq -8\}$ B. Intercepts are 0 C. No symmetry

D. $\lim_{x \rightarrow \infty} \frac{x^2}{x+8} = \infty$, but $f(x) - (x - 8) = \frac{64}{x+8} \rightarrow 0$ as $x \rightarrow \infty$, so $y = x - 8$ is a slant asymptote.

$\lim_{x \rightarrow -8^+} \frac{x^2}{x+8} = \infty$ and $\lim_{x \rightarrow -8^-} \frac{x^2}{x+8} = -\infty$, so $x = -8$ is a VA.

E. $f'(x) = 1 - \frac{64}{(x+8)^2} = \frac{x(x+16)}{(x+8)^2} > 0 \Leftrightarrow x > 0$ or $x < -16$,

so f is increasing on $(-\infty, -16)$ and $(0, \infty)$ and decreasing on

$(-16, -8)$ and $(-8, 0)$. F. Local maximum value $f(-16) = -32$,

local minimum value $f(0) = 0$ G. $f''(x) = 128/(x+8)^3 > 0 \Leftrightarrow$

$x > -8$, so f is CU on $(-8, \infty)$ and CD on $(-\infty, -8)$. No IP

H.

24. $y = f(x) = x + \sqrt{1-x}$ A. $D = \{x \mid x \leq 1\} = (-\infty, 1]$ B. y -intercept = 1; x -intercepts occur when

$x + \sqrt{1-x} = 0 \Rightarrow \sqrt{1-x} = -x \Rightarrow 1-x = x^2 \Rightarrow x^2 + x - 1 = 0 \Rightarrow x = \frac{-1 \pm \sqrt{5}}{2}$, but

the larger root is extraneous, so the only x -intercept is $\frac{-1-\sqrt{5}}{2}$. C. No symmetry D. No asymptote

E. $f'(x) = 1 - 1/(2\sqrt{1-x}) = 0 \Leftrightarrow 2\sqrt{1-x} = 1 \Leftrightarrow$

$1-x = \frac{1}{4} \Leftrightarrow x = \frac{3}{4}$ and $f'(x) > 0 \Leftrightarrow x < \frac{3}{4}$, so f is increasing

on $(-\infty, \frac{3}{4})$, decreasing on $(\frac{3}{4}, 1)$. F. Local maximum value $f(\frac{3}{4}) = \frac{5}{4}$

G. $f''(x) = -\frac{1}{4(1-x)^{3/2}} < 0 \Leftrightarrow x < 1$, so f is CD on $(-\infty, 1)$.

No IP

H.

25. $y = f(x) = x\sqrt{2+x}$ A. $D = [-2, \infty)$ B. y -intercept: $f(0) = 0$; x -intercepts: -2 and 0 C. No

symmetry D. No asymptote E. $f'(x) = \frac{x}{2\sqrt{2+x}} + \sqrt{2+x} = \frac{1}{2\sqrt{2+x}} [x + 2(2+x)] = \frac{3x+4}{2\sqrt{2+x}} = 0$

when $x = -\frac{4}{3}$, so f is decreasing on $(-2, -\frac{4}{3})$ and increasing on $(-\frac{4}{3}, \infty)$. F. Local minimum value

$f(-\frac{4}{3}) = -\frac{4}{3}\sqrt{\frac{2}{3}} = -\frac{4\sqrt{6}}{9} \approx -1.09$, no local maximum

G. $f''(x) = \frac{2\sqrt{2+x} \cdot 3 - (3x+4)\frac{1}{\sqrt{2+x}}}{4(2+x)}$
 $= \frac{6(2+x) - (3x+4)}{4(2+x)^{3/2}} = \frac{3x+8}{4(2+x)^{3/2}}$

$f''(x) > 0$ for $x > -2$, so f is CU on $(-2, \infty)$. No IP

H.

26. $y = f(x) = \sqrt{x} - \sqrt[3]{x}$ A. $D = [0, \infty)$ B. y -intercept 0; x -intercepts 0, 1

C. No symmetry D. $\lim_{x \rightarrow \infty} (x^{1/2} - x^{1/3}) = \lim_{x \rightarrow \infty} [x^{1/3}(x^{1/6} - 1)] = \infty$, no asymptote

E. $f'(x) = \frac{1}{2}x^{-1/2} - \frac{1}{3}x^{-2/3} = \frac{3x^{1/6} - 2}{6x^{2/3}} > 0 \Leftrightarrow 3x^{1/6} > 2 \Leftrightarrow x > (\frac{2}{3})^6$, so f is increasing on

$(\frac{2}{3})^6, \infty)$ and decreasing on $(0, (\frac{2}{3})^6)$. F. $f((\frac{2}{3})^6) = -\frac{4}{27}$ is a local minimum value.

G. $f''(x) = -\frac{1}{4}x^{-3/2} + \frac{2}{9}x^{-5/3} = \frac{8 - 9x^{1/6}}{36x^{5/3}} > 0 \Leftrightarrow x^{1/6} < \frac{8}{9}$

$\Leftrightarrow x < (\frac{8}{9})^6$, so f is CU on $(0, (\frac{8}{9})^6)$ and CD on $((\frac{8}{9})^6, \infty)$.

IP at $((\frac{8}{9})^6, -\frac{64}{729})$

27. $y = f(x) = \sin^2 x - 2 \cos x$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = -2$ C. $f(-x) = f(x)$, so

f is symmetric with respect to the y -axis. f has period 2π . D. No asymptote

E. $y' = 2 \sin x \cos x + 2 \sin x = 2 \sin x (\cos x + 1)$. $y' = 0 \Leftrightarrow \sin x = 0$ or $\cos x = -1 \Leftrightarrow x = n\pi$ or $x = (2n+1)\pi$. $y' > 0$ when $\sin x > 0$, since $\cos x + 1 \geq 0$ for all x . Therefore, $y' > 0$ (and so f is increasing)

on $(2n\pi, (2n+1)\pi)$; $y' < 0$ (and so f is decreasing) on $((2n-1)\pi, 2n\pi)$. F. Local maximum values are

$f((2n+1)\pi) = 2$; local minimum values are $f(2n\pi) = -2$. G. $y' = \sin 2x + 2 \sin x \Rightarrow$

$$y'' = 2 \cos 2x + 2 \cos x = 2(2 \cos^2 x - 1) + 2 \cos x = 4 \cos^2 x + 2 \cos x - 2$$

$$= 2(2 \cos^2 x + \cos x - 1) = 2(2 \cos x - 1)(\cos x + 1)$$

$y'' = 0 \Leftrightarrow \cos x = \frac{1}{2}$ or $-1 \Leftrightarrow x = 2n\pi \pm \frac{\pi}{3}$ or $x = (2n+1)\pi$. $y'' > 0$ (and so f is CU) on

$(2n\pi - \frac{\pi}{3}, 2n\pi + \frac{\pi}{3})$; $y'' \leq 0$ (and so f is CD) on $(2n\pi + \frac{\pi}{3}, 2n\pi + \frac{5\pi}{3})$. There are inflection points

at $(2n\pi \pm \frac{\pi}{3}, -\frac{1}{4})$.

28. $y = f(x) = 4x - \tan x$, $-\frac{\pi}{2} < x < \frac{\pi}{2}$ A. $D = (-\frac{\pi}{2}, \frac{\pi}{2})$. B. y -intercept $= f(0) = 0$ C. $f(-x) = -f(x)$,

so the curve is symmetric about $(0, 0)$. D. $\lim_{x \rightarrow \pi/2^-} (4x - \tan x) = -\infty$, $\lim_{x \rightarrow -\pi/2^+} (4x - \tan x) = \infty$, so $x = \frac{\pi}{2}$

and $x = -\frac{\pi}{2}$ are VA. E. $f'(x) = 4 - \sec^2 x > 0 \Leftrightarrow \sec x < 2 \Leftrightarrow$

$\cos x > \frac{1}{2} \Leftrightarrow -\frac{\pi}{3} < x < \frac{\pi}{3}$, so f is increasing on $(-\frac{\pi}{3}, \frac{\pi}{3})$ and

decreasing on $(-\frac{\pi}{2}, -\frac{\pi}{3})$ and $(\frac{\pi}{3}, \frac{\pi}{2})$. F. $f(\frac{\pi}{3}) = \frac{4\pi}{3} - \sqrt{3}$ is a

local maximum value, $f(-\frac{\pi}{3}) = \sqrt{3} - \frac{4\pi}{3}$ is a local minimum value.

G. $f''(x) = -2\sec^2 x \tan x > 0 \Leftrightarrow \tan x < 0 \Leftrightarrow -\frac{\pi}{2} < x < 0$,

so f is CU on $(-\frac{\pi}{2}, 0)$ and CD on $(0, \frac{\pi}{2})$. IP at $(0, 0)$

$$29. f(x) = \frac{x^2 - 1}{x^3} \Rightarrow f'(x) = \frac{x^3(2x) - (x^2 - 1)3x^2}{x^6} = \frac{3 - x^2}{x^4} \Rightarrow$$

$$f''(x) = \frac{x^4(-2x) - (3 - x^2)4x^3}{x^8} = \frac{2x^2 - 12}{x^5}$$

Estimates: From the graphs of f' and f'' , it appears that f is increasing on

$(-1.73, 0)$ and $(0, 1.73)$ and decreasing on $(-\infty, -1.73)$ and $(1.73, \infty)$;

f has a local maximum of about $f(1.73) = 0.38$ and a local minimum of

about $f(-1.7) = -0.38$; f is CU on $(-2.45, 0)$ and $(2.45, \infty)$, and CD

on $(-\infty, -2.45)$ and $(0, 2.45)$; and f has inflection points at about

$(-2.45, -0.34)$ and $(2.45, 0.34)$.

Exact: Now $f'(x) = \frac{3 - x^2}{x^4}$ is positive for $0 < x^2 < 3$, that is, f is

increasing on $(-\sqrt{3}, 0)$ and $(0, \sqrt{3})$; and $f'(x)$ is negative (and so f is

decreasing) on $(-\infty, -\sqrt{3})$ and $(\sqrt{3}, \infty)$. $f'(x) = 0$ when $x = \pm\sqrt{3}$.

f' goes from positive to negative at $x = \sqrt{3}$, so f has a local maximum of

$f(\sqrt{3}) = \frac{(\sqrt{3})^2 - 1}{(\sqrt{3})^3} = \frac{2\sqrt{3}}{9}$; and since f is odd, we know that maxima on

the interval $(0, \infty)$ correspond to minima on $(-\infty, 0)$, so f has a local

minimum of $f(-\sqrt{3}) = -\frac{2\sqrt{3}}{9}$. Also, $f''(x) = \frac{2x^2 - 12}{x^5}$ is positive (so

f is CU) on $(-\sqrt{6}, 0)$ and $(\sqrt{6}, \infty)$, and negative (so f is CD) on

$(-\infty, -\sqrt{6})$ and $(0, \sqrt{6})$. There are IP at $(\sqrt{6}, \frac{5\sqrt{6}}{36})$ and

$(-\sqrt{6}, -\frac{5\sqrt{6}}{36})$.

$$30. f(x) = \frac{\sqrt[3]{x}}{1-x} = x^{1/3}(1-x)^{-1} \Rightarrow$$

$$f'(x) = x^{1/3}(-1)(1-x)^{-2}(-1) + (1-x)^{-1}\left(\frac{1}{3}\right)x^{-2/3} = \frac{x^{-2/3}}{3} \frac{1+2x}{(x-1)^2} \Rightarrow$$

$$f''(x) = \frac{x^{-2/3}}{3} \frac{(x-1)^2(2) - (1+2x)(2)(x-1)}{(x-1)^4} + \frac{1+2x}{(x-1)^2} \left(\frac{-2x^{-5/3}}{9} \right) = -\frac{2x^{-5/3}}{9} \frac{5x^2+5x-1}{(x-1)^3}$$

From the graphs, it appears that f is increasing on $(-0.50, 1)$ and $(1, \infty)$, with a vertical asymptote at $x = 1$, and decreasing on $(-\infty, -0.50)$; f has no local maximum, but a local minimum of about $f(-0.50) = -0.53$; f is CU on $(-1.17, 0)$ and $(0.17, 1)$ and CD on $(-\infty, -1.17)$, $(0, 0.17)$ and $(1, \infty)$; and f has inflection points at about $(-1.17, -0.49)$, $(0, 0)$ and $(0.17, 0.67)$. Note also that $\lim_{x \rightarrow \pm\infty} f(x) = 0$, so $y = 0$ is a horizontal asymptote.

$$31. f(x) = 3x^6 - 5x^5 + x^4 - 5x^3 - 2x^2 + 2 \Rightarrow f'(x) = 18x^5 - 25x^4 + 4x^3 - 15x^2 - 4x \Rightarrow$$

$$f''(x) = 90x^4 - 100x^3 + 12x^2 - 30x - 4$$

From the graphs of f' and f'' , it appears that f is increasing on $(-0.23, 0)$ and $(1.62, \infty)$ and decreasing on $(-\infty, -0.23)$ and $(0, 1.62)$; f has a local maximum of about $f(0) = 2$ and local minima

of about $f(-0.23) = 1.96$ and $f(1.62) = -19.2$; f is CU on $(-\infty, -0.12)$ and $(1.24, \infty)$ and CD on $(-0.12, 1.24)$; and f has inflection points at about $(-0.12, 1.98)$ and $(1.24, -12.1)$.

$$32. f(x) = \sin x \cos^2 x \Rightarrow f'(x) = \cos^3 x - 2 \sin^2 x \cos x \Rightarrow f''(x) = -7 \sin x \cos^2 x + 2 \sin^3 x$$

From the graphs of f' and f'' , it appears that f is increasing on $(0, 0.62)$, $(1.57, 2.53)$, $(3.76, 4.71)$ and $(5.67, 2\pi)$ and decreasing on $(0.62, 1.57)$, $(2.53, 3.76)$ and $(4.71, 5.67)$; f has local maxima of about $f(0.62) = f(2.53) = 0.38$ and $f(4.71) = 0$ and local minima of about $f(1.57) = 0$ and $f(3.76) = f(5.67) = -0.38$; f is CU on $(1.08, 2.06)$, $(3.14, 4.22)$ and $(5.20, 2\pi)$ and CD on $(0, 1.08)$, $(2.06, 3.14)$ and $(4.22, 5.20)$; and f has inflection points at about $(0, 0)$, $(1.08, 0.20)$, $(2.06, 0.20)$, $(3.14, 0)$, $(4.22, -0.20)$, $(5.20, -0.20)$ and $(2\pi, 0)$.

33. $f(x) = x^{101} + x^{51} + x - 1 = 0$. Since f is continuous and $f(0) = -1$ and $f(1) = 2$, the equation has at least one root in $(0, 1)$, by the Intermediate Value Theorem. Suppose the equation has two roots, a and b , with $a < b$.

Then $f(a) = 0 = f(b)$, so by the Mean Value Theorem, there is a number x in (a, b) such that

$$f'(x) = \frac{f(b) - f(a)}{b - a} = \frac{0}{b - a} = 0, \text{ so } f' \text{ has a root in } (a, b). \text{ But this is impossible since}$$

$$f'(x) = 101x^{100} + 51x^{50} + 1 \geq 1 \text{ for all } x.$$

34. By the Mean Value Theorem, $f'(c) = \frac{f(4) - f(0)}{4 - 0} \Leftrightarrow 4f'(c) = f(4) - 1$ for some c with $0 < c < 4$. Since

$$2 \leq f'(c) \leq 5, \text{ we have } 4(2) \leq 4f'(c) \leq 4(5) \Leftrightarrow 4(2) \leq f(4) - 1 \leq 4(5) \Leftrightarrow 8 \leq f(4) - 1 \leq 20 \Leftrightarrow 9 \leq f(4) \leq 21.$$

35. Since f is continuous on $[32, 33]$ and differentiable on $(32, 33)$, then by the Mean Value Theorem there exists a

$$\text{number } c \text{ in } (32, 33) \text{ such that } f'(c) = \frac{\sqrt[5]{33} - \sqrt[5]{32}}{33 - 32} = \sqrt[5]{33} - 2, \text{ but } \frac{1}{5}c^{-4/5} > 0 \Rightarrow \sqrt[5]{33} - 2 > 0$$

$$\Rightarrow \sqrt[5]{33} > 2. \text{ Also } f' \text{ is decreasing, so that } f'(c) < f'(32) = \frac{1}{5}(32)^{-4/5} = 0.0125 \Rightarrow$$

$$0.0125 > f'(c) = \sqrt[5]{33} - 2 \Rightarrow \sqrt[5]{33} < 2.0125. \text{ Therefore, } 2 < \sqrt[5]{33} < 2.0125.$$

36. For $(1, 6)$ to be on the curve $y = x^3 + ax^2 + bx + 1$, we have that $6 = 1 + a + b + 1 \Rightarrow b = 4 - a$. Now

$$y' = 3x^2 + 2ax + b \text{ and } y'' = 6x + 2a. \text{ Also, for } (1, 6) \text{ to be an inflection point it must be true that}$$

$$y''(1) = 6(1) + 2a = 0 \Rightarrow a = -3 \Rightarrow b = 4 - (-3) = 7. \text{ Note that with } a = -3, \text{ we have}$$

$$y'' = 6x - 6 = 6(x - 1), \text{ so } y'' \text{ changes sign at } x = 1, \text{ proving that } (1, 6) \text{ is a point of inflection. [This does not follow from the fact that } y''(1) = 0.]$$

37. (a) $g(x) = f(x^2) \Rightarrow g'(x) = 2xf'(x^2)$ by the Chain Rule. Since $f'(x) > 0$ for all $x \neq 0$, we must have

$$f'(x^2) > 0 \text{ for } x \neq 0, \text{ so } g'(x) = 0 \Leftrightarrow x = 0. \text{ Now } g'(x) \text{ changes sign (from negative to positive) at}$$

$x = 0$, since one of its factors, $f'(x^2)$, is positive for all x , and its other factor, $2x$, changes from negative to positive at this point, so by the First Derivative Test, f has a local and absolute minimum at $x = 0$.

- (b) $g'(x) = 2xf'(x^2) \Rightarrow g''(x) = 2[xf''(x^2)(2x) + f'(x^2)] = 4x^2f''(x^2) + 2f'(x^2)$ by the Product Rule and the Chain Rule. But $x^2 > 0$ for all $x \neq 0$, $f''(x^2) > 0$ (since f is CU for $x > 0$), and $f'(x^2) > 0$ for all $x \neq 0$, so since all of its factors are positive, $g''(x) > 0$ for $x \neq 0$. Whether $g''(0)$ is positive or 0 doesn't matter (since the sign of g'' does not change there); g is concave upward on $\mathbb{R}$.

38. Call the two integers x and y . Then $x + 4y = 1000$, so $x = 1000 - 4y$. Their product is $P = xy = (1000 - 4y)y$, so our problem is to maximize the function $P(y) = 1000y - 4y^2$, where $0 < y < 250$ and y is an integer. $P'(y) = 1000 - 8y$, so $P'(y) = 0 \Leftrightarrow y = 125$. $P''(y) = -8 < 0$, so $P(125) = 62,500$ is an absolute maximum. Since the optimal y turned out to be an integer, we have found the desired pair of numbers, namely $x = 1000 - 4(125) = 500$ and $y = 125$.

39. If $B = 0$, the line is vertical and the distance from $x = -\frac{C}{A}$ to (x_1, y_1) is $\left|x_1 + \frac{C}{A}\right| = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}}$, so assume $B \neq 0$. The square of the distance from (x_1, y_1) to the line is $f(x) = (x - x_1)^2 + (y - y_1)^2$ where $Ax + By + C = 0$, so we minimize $f(x) = (x - x_1)^2 + \left(-\frac{A}{B}x - \frac{C}{B} - y_1\right)^2 \Rightarrow$
 $f'(x) = 2(x - x_1) + 2\left(-\frac{A}{B}x - \frac{C}{B} - y_1\right)\left(-\frac{A}{B}\right)$. $f'(x) = 0 \Rightarrow x = \frac{B^2x_1 - AB y_1 - AC}{A^2 + B^2}$ and this gives a minimum since $f''(x) = 2\left(1 + \frac{A^2}{B^2}\right) > 0$. Substituting this value of x into $f(x)$ and simplifying gives
 $f(x) = \frac{(Ax_1 + By_1 + C)^2}{A^2 + B^2}$, so the minimum distance is $\sqrt{f(x)} = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}}$.

40. On the hyperbola $xy = 8$, if $d(x)$ is the distance from the point $(x, y) = (x, 8/x)$ to the point $(3, 0)$, then $[d(x)]^2 = (x - 3)^2 + 64/x^2 = f(x)$. $f'(x) = 2(x - 3) - 128/x^3 = 0 \Rightarrow x^4 - 3x^3 - 64 = 0 \Rightarrow (x - 4)(x^3 + x^2 + 4x + 16) = 0 \Rightarrow x = 4$ since the solution must have $x > 0$. Then $y = \frac{8}{4} = 2$, so the point is $(4, 2)$.

41.

By similar triangles, $\frac{y}{x} = \frac{r}{\sqrt{x^2 - 2rx}}$, so the area of the triangle is

$$A(x) = \frac{1}{2}(2y)x = xy = \frac{rx^2}{\sqrt{x^2 - 2rx}} \Rightarrow$$

$$A'(x) = \frac{2rx\sqrt{x^2 - 2rx} - rx^2(x - r)/\sqrt{x^2 - 2rx}}{x^2 - 2rx}$$

$$= \frac{rx^2(x - 3r)}{(x^2 - 2rx)^{3/2}} = 0 \text{ when } x = 3r.$$

$A'(x) < 0$ when $2r < x < 3r$, $A'(x) > 0$ when $x > 3r$. So $x = 3r$ gives a minimum and $A(3r) = r(9r^2)/(\sqrt{3}r) = 3\sqrt{3}r^2$.

42.

The volume of the cone is

$$V = \frac{1}{3}\pi y^2(r+x) = \frac{1}{3}\pi(r^2 - x^2)(r+x), \quad -r \leq x \leq r.$$

$$\begin{aligned} V'(x) &= \frac{\pi}{3} [(r^2 - x^2)(1) + (r+x)(-2x)] \\ &= \frac{\pi}{3} [(r+x)(r-x-2x)] = \frac{\pi}{3}(r+x)(r-3x) \\ &= 0 \text{ when } x = -r \text{ or } x = r/3. \end{aligned}$$

 Now $V(r) = 0 = V(-r)$, so the maximum occurs at $x = r/3$

$$\text{and the volume is } V\left(\frac{r}{3}\right) = \frac{\pi}{3}\left(r^2 - \frac{r^2}{9}\right)\left(\frac{4r}{3}\right) = \frac{32\pi r^3}{81}.$$

43.

We minimize

$$L(x) = |PA| + |PB| + |PC| = 2\sqrt{x^2 + 16} + (5 - x),$$

$$0 \leq x \leq 5. \quad L'(x) = 2x/\sqrt{x^2 + 16} - 1 = 0 \Leftrightarrow$$

$$2x = \sqrt{x^2 + 16} \Leftrightarrow 4x^2 = x^2 + 16 \Leftrightarrow x = \frac{4}{\sqrt{3}}.$$

$L(0) = 13$, $L\left(\frac{4}{\sqrt{3}}\right) \approx 11.9$, $L(5) \approx 12.8$, so the minimum occurs when $x = \frac{4}{\sqrt{3}} \approx 2.3$.

44.

 If $|CD| = 2$, the last part of $L(x)$ changes from $(5 - x)$ to

$$(2 - x) \text{ with } 0 \leq x \leq 2. \text{ But we still get } L'(x) = 0 \Leftrightarrow$$

$$x = \frac{4}{\sqrt{3}}, \text{ which isn't in the interval } [0, 2]. \text{ Now } L(0) = 10$$

and $L(2) = 2\sqrt{20} = 4\sqrt{5} \approx 8.9$. The minimum occurs when $P = C$.

$$45. \quad v = K\sqrt{\frac{L}{C} + \frac{C}{L}} \Rightarrow \frac{dv}{dL} = \frac{K}{2\sqrt{(L/C) + (C/L)}}\left(\frac{1}{C} - \frac{C}{L^2}\right) = 0 \Leftrightarrow \frac{1}{C} = \frac{C}{L^2} \Leftrightarrow L^2 = C^2 \Leftrightarrow$$

$L = C$. This gives the minimum velocity since $v' < 0$ for $0 < L < C$ and $v' > 0$ for $L > C$.

46.

 We minimize the surface area $S = \pi r^2 + 2\pi rh + \frac{1}{2}(4\pi r^2) = 3\pi r^2 + 2\pi rh$.

Solving $V = \pi r^2 h + \frac{2}{3}\pi r^3$ for h , we get $h = \frac{V - \frac{2}{3}\pi r^3}{\pi r^2} = \frac{V}{\pi r^2} - \frac{2}{3}r$, so

$$S(r) = 3\pi r^2 + 2\pi r\left[\frac{V}{\pi r^2} - \frac{2}{3}r\right] = \frac{5}{3}\pi r^2 + \frac{2V}{r}.$$

$$S'(r) = -\frac{2V}{r^2} + \frac{10}{3}\pi r = \frac{\frac{10}{3}\pi r^3 - 2V}{r^2} = 0 \Leftrightarrow \frac{10}{3}\pi r^3 = 2V$$

$$\Leftrightarrow r^3 = \frac{3V}{5\pi} \Leftrightarrow r = \sqrt[3]{\frac{3V}{5\pi}}. \text{ This gives an absolute minimum since } S'(r) < 0 \text{ for } 0 < r < \sqrt[3]{\frac{3V}{5\pi}} \text{ and}$$

$$S'(r) > 0 \text{ for } r > \sqrt[3]{\frac{3V}{5\pi}}. \text{ Thus, } h = \frac{V - \frac{2}{3}\pi \cdot \frac{3V}{5\pi}}{\pi \sqrt[3]{\frac{3V}{5\pi}}} = \frac{(V - \frac{2}{5}V) \sqrt[3]{(5\pi)^2}}{\pi \sqrt[3]{(3V)^2}} = \frac{3V \sqrt[3]{(5\pi)^2}}{5\pi \sqrt[3]{(3V)^2}} = \sqrt[3]{\frac{3V}{5\pi}} = r.$$

47. Let x denote the number of \$1 decreases in ticket price. Then the ticket price is $\$12 - \$1(x)$, and the average attendance is $11,000 + 1000(x)$. Now the revenue per game is

$$\begin{aligned} R(x) &= (\text{price per person}) \times (\text{number of people per game}) \\ &= (12 - x)(11,000 + 1000x) = -1000x^2 + 1000x + 132,000 \end{aligned}$$

for $0 \leq x \leq 4$ (since the seating capacity is 15,000) $\Rightarrow R'(x) = -2000x + 1000 = 0 \Leftrightarrow x = 0.5$.

This is a maximum since $R''(x) = -2000 < 0$ for all x . Now we must check the value of

$R(x) = (12 - x)(11,000 + 1000x)$ at $x = 0.5$ and at the endpoints of the domain to see which value of x gives the maximum value of R . $R(0) = (12)(11,000) = 132,000$, $R(0.5) = (11.5)(11,500) = 132,250$, and $R(4) = (8)(15,000) = 120,000$. Thus, the maximum revenue of \$132,250 per game occurs when the average attendance is 11,500 and the ticket price is \$11.50.

48. (a) $C'(x) = 1800 + 25x - 0.2x^2 + 0.001x^3$ and

$R(x) = xp(x) = 48.2x - 0.03x^2$. The profit is maximized when $C'(x) = R'(x)$.

From the figure, we estimate that the tangents are parallel when $x \approx 160$.

- (b) $C'(x) = 25 - 0.4x + 0.003x^2$ and $R'(x) = 48.2 - 0.06x$. $C'(x) = R'(x) \Rightarrow$

$$0.003x^2 - 0.34x - 23.2 = 0 \Rightarrow x_1 \approx 161.3 \ (x > 0). \quad R''(x) = -0.06 \text{ and}$$

$C''(x) = -0.4 + 0.006x$, so $R''(x_1) = -0.06 < C''(x_1) \approx 0.57 \Rightarrow$ profit is maximized by producing 161 units.

- (c) $c(x) = \frac{C(x)}{x} = \frac{1800}{x} + 25 - 0.2x + 0.001x^2$ is the average cost.

Since the average cost is minimized when the marginal cost equals the average cost, we graph $c(x)$ and $C'(x)$ and estimate the point of intersection. From the figure, $C'(x) = c(x) \Leftrightarrow x \approx 144$.

49. $f(x) = x^5 - x^4 + 3x^2 - 3x - 2 \Rightarrow f'(x) = 5x^4 - 4x^3 + 6x - 3$, so

$$x_{n+1} = x_n - \frac{x_n^5 - x_n^4 + 3x_n^2 - 3x_n - 2}{5x_n^4 - 4x_n^3 + 6x_n - 3}. \text{ Now } x_1 = 1 \Rightarrow x_2 = 1.5 \Rightarrow x_3 \approx 1.343860 \Rightarrow$$

$x_4 \approx 1.300320 \Rightarrow x_5 \approx 1.297396 \Rightarrow x_6 \approx 1.297383 \approx x_7$, so the root in $[1, 2]$ is 1.297383, to six decimal places.

50. Graphing $y = \sin x$ and $y = x^2 - 3x + 1$ shows that there are two roots, one about 0.3 and the other about 2.8.

$$f(x) = \sin x - x^2 + 3x - 1 \Rightarrow f'(x) = \cos x - 2x + 3 \Rightarrow$$

$$x_{n+1} = x_n - \frac{\sin x_n - x_n^2 + 3x_n - 1}{\cos x_n - 2x_n + 3}. \text{ Now } x_1 = 0.3 \Rightarrow$$

$$x_2 \approx 0.268552 \Rightarrow x_3 \approx 0.268881 \approx x_4 \text{ and } x_1 = 2.8 \Rightarrow$$

$x_2 \approx 2.770354 \Rightarrow x_3 \approx 2.770058 \approx x_4$, so to six decimal places, the roots are 0.268881 and 2.770058.

51. $f(t) = \cos t + t - t^2 \Rightarrow f'(t) = -\sin t + 1 - 2t$. $f'(t)$ exists

for all t , so to find the maximum of f , we can examine the zeros of f' .

From the graph of f' , we see that a good choice for t_1 is $t_1 = 0.3$.

Use $g(t) = -\sin t + 1 - 2t$ and $g'(t) = -\cos t - 2$ to obtain

$$t_2 \approx 0.33535293, t_3 \approx 0.33541803 \approx t_4. \text{ Since}$$

$f''(t) = -\cos t - 2 < 0$ for all t , $f(0.33541803) \approx 1.16718557$ is the absolute maximum.

52. $y = f(x) = x \sin x$, $0 \leq x \leq 2\pi$. **A.** $D = [0, 2\pi]$ **B.** y -intercept: $f(0) = 0$; x -intercepts: $f(x) = 0 \Leftrightarrow x = 0$ or $\sin x = 0 \Leftrightarrow x = 0, \pi$, or 2π . **C.** There is no symmetry on D , but if f is defined for all real numbers x , then f is an even function. **D.** No asymptote **E.** $f'(x) = x \cos x + \sin x$. To find critical numbers in $(0, 2\pi)$, we graph f' and see that there are two critical numbers, about 2 and 4.9. To find them more precisely, we use Newton's method, setting $g(x) = f'(x) = x \cos x + \sin x$, so that $g'(x) = f''(x) = 2 \cos x - x \sin x$ and
- $$x_{n+1} = x_n - \frac{x_n \cos x_n + \sin x_n}{2 \cos x_n - x_n \sin x_n}. \quad x_1 = 2 \Rightarrow x_2 \approx 2.029048, x_3 \approx 2.028758 \approx x_4 \text{ and } x_1 = 4.9 \Rightarrow$$
- $$x_2 \approx 4.913214, x_3 \approx 4.913180 \approx x_4, \text{ so the critical numbers, to six decimal places, are } r_1 = 2.028758 \text{ and } r_2 = 4.913180.$$
- By checking sample values of f' in $(0, r_1)$, (r_1, r_2) , and $(r_2, 2\pi)$, we see that f is increasing on $(0, r_1)$, decreasing on (r_1, r_2) , and increasing on $(r_2, 2\pi)$. **F.** Local maximum value $f(r_1) \approx 1.819706$, local minimum value $f(r_2) \approx -4.814470$. **G.** $f''(x) = 2 \cos x - x \sin x$. To find points where $f''(x) = 0$, we graph f'' and find that $f''(x) = 0$ at about 1 and 3.6. To find the values more precisely, we use Newton's method. Set
- $$h(x) = f''(x) = 2 \cos x - x \sin x. \text{ Then } h'(x) = -3 \sin x - x \cos x, \text{ so } x_{n+1} = x_n - \frac{2 \cos x_n - x_n \sin x_n}{-3 \sin x_n - x_n \cos x_n}.$$
- $$x_1 = 1 \Rightarrow x_2 \approx 1.078028, x_3 \approx 1.076874 \approx x_4 \text{ and } x_1 = 3.6 \Rightarrow x_2 \approx 3.643996, x_3 \approx 3.643597 \approx x_4,$$
- so the zeros of f'' , to six decimal places, are $r_3 = 1.076874$ and $r_4 = 3.643597$. By checking sample values of f'' in $(0, r_3)$, (r_3, r_4) , and $(r_4, 2\pi)$, we see that f is CU on $(0, r_3)$, CD on (r_3, r_4) , and CU on $(r_4, 2\pi)$. f has inflection points at $(r_3, f(r_3) \approx 0.948166)$ and $(r_4, f(r_4) \approx -1.753240)$.

$$53. f'(x) = \sqrt{x^5} - 4/\sqrt[5]{x} = x^{5/2} - 4x^{-1/5} \Rightarrow f(x) = \frac{2}{7}x^{7/2} - 4\left(\frac{5}{4}x^{4/5}\right) + C = \frac{2}{7}x^{7/2} - 5x^{4/5} + C$$

$$54. f'(x) = 8x - 3\sec^2 x \Rightarrow f(x) = 8\left(\frac{1}{2}x^2\right) - 3\tan x + C_n = 4x^2 - 3\tan x + C_n \text{ on the interval } \left(n\pi - \frac{\pi}{2}, n\pi + \frac{\pi}{2}\right).$$

$$55. f'(t) = 2t - 3\sin t \Rightarrow f(t) = t^2 + 3\cos t + C.$$

$$f(0) = 3 + C \text{ and } f(0) = 5 \Rightarrow C = 2, \text{ so } f(t) = t^2 + 3\cos t + 2.$$

$$56. f'(u) = \frac{u^2 + \sqrt{u}}{u} = u + u^{-1/2} \Rightarrow f(u) = \frac{1}{2}u^2 + 2u^{1/2} + C.$$

$$f(1) = \frac{1}{2} + 2 + C \text{ and } f(1) = 3 \Rightarrow C = \frac{1}{2}, \text{ so } f(u) = \frac{1}{2}u^2 + 2\sqrt{u} + \frac{1}{2}.$$

$$57. f''(x) = 1 - 6x + 48x^2 \Rightarrow f'(x) = x - 3x^2 + 16x^3 + C. \quad f'(0) = C \text{ and } f'(0) = 2 \Rightarrow C = 2, \text{ so } f'(x) = x - 3x^2 + 16x^3 + 2 \text{ and hence, } f(x) = \frac{1}{2}x^2 - x^3 + 4x^4 + 2x + D. \quad f(0) = D \text{ and } f(0) = 1 \Rightarrow D = 1, \text{ so } f(x) = \frac{1}{2}x^2 - x^3 + 4x^4 + 2x + 1.$$

$$58. f''(x) = 2x^3 + 3x^2 - 4x + 5 \Rightarrow f'(x) = \frac{1}{2}x^4 + x^3 - 2x^2 + 5x + C \Rightarrow$$

$$f(x) = \frac{1}{10}x^5 + \frac{1}{4}x^4 - \frac{2}{3}x^3 + \frac{5}{2}x^2 + Cx + D. \quad f(0) = D \text{ and } f(0) = 2 \Rightarrow D = 2.$$

$$f(1) = \frac{1}{10} + \frac{1}{4} - \frac{2}{3} + \frac{5}{2} + C + 2 \text{ and } f(1) = 0 \Rightarrow C = -\frac{6}{60} - \frac{15}{60} + \frac{40}{60} - \frac{150}{60} - \frac{120}{60} = -\frac{251}{60}, \text{ so}$$

$$f(x) = \frac{1}{10}x^5 + \frac{1}{4}x^4 - \frac{2}{3}x^3 + \frac{5}{2}x^2 - \frac{251}{60}x + 2.$$

$$59. f(x) = x^2 \sin(x^2), \quad 0 \leq x \leq \pi$$

$$60. f(x) = x^4 + x^3 + cx^2 \Rightarrow f'(x) = 4x^3 + 3x^2 + 2cx. \text{ This is 0 when } x(4x^2 + 3x + 2c) = 0 \Leftrightarrow$$

$x = 0$ or $4x^2 + 3x + 2c = 0$. Using the quadratic formula, we find that the roots of this last equation are

$$x = \frac{-3 \pm \sqrt{9 - 32c}}{8}. \text{ Now if } 9 - 32c < 0 \Leftrightarrow c > \frac{9}{32}, \text{ then } (0, 0) \text{ is the only critical point, a minimum.}$$

If $c = \frac{9}{32}$, then there are two critical points (a minimum at $x = 0$, and a horizontal tangent with no maximum or minimum at $x = -\frac{3}{8}$) and if $c < \frac{9}{32}$, then there are three critical points except when $c = 0$, in which case the root with the + sign coincides with the critical point at $x = 0$. For $0 < c < \frac{9}{32}$, there is a minimum at

$$x = -\frac{3}{8} - \frac{\sqrt{9 - 32c}}{8}, \text{ a maximum at } x = -\frac{3}{8} + \frac{\sqrt{9 - 32c}}{8}, \text{ and a minimum at } x = 0. \text{ For } c = 0, \text{ there is a}$$

minimum at $x = -\frac{3}{4}$ and a horizontal tangent with no extremum at $x = 0$, and for $c < 0$, there is a maximum at $x = 0$, and there are minima at $x = -\frac{3}{8} \pm \frac{\sqrt{9-32c}}{8}$. Now we calculate $f''(x) = 12x^2 + 6x + 2c$. The roots of this equation are $x = \frac{-6 \pm \sqrt{36 - 4 \cdot 12 \cdot 2c}}{24}$. So if $36 - 96c \leq 0 \Leftrightarrow c \geq \frac{3}{8}$, then there is no inflection point. If $c < \frac{3}{8}$, then there are two inflection points at $x = -\frac{1}{4} \pm \frac{\sqrt{9-24c}}{12}$.

Value of c	No. of CP	No. of IP
$c < 0$	3	2
$c = 0$	2	2
$0 < c < \frac{9}{32}$	3	2
$c = \frac{9}{32}$	2	2
$\frac{9}{32} < c < \frac{3}{8}$	1	2
$c \geq \frac{3}{8}$	1	0

61. Choosing the positive direction to be upward, we have $a(t) = -9.8 \Rightarrow v(t) = -9.8t + v_0$, but $v(0) = 0 = v_0 \Rightarrow v(t) = -9.8t = s'(t) \Rightarrow s(t) = -4.9t^2 + s_0$, but $s(0) = s_0 = 500 \Rightarrow s(t) = -4.9t^2 + 500$. When $s = 0$, $-4.9t^2 + 500 = 0 \Rightarrow t_1 = \sqrt{\frac{500}{4.9}} \approx 10.1 \Rightarrow v(t_1) = -9.8\sqrt{\frac{500}{4.9}} \approx -98.995$ m/s. Since the canister has been designed to withstand an impact velocity of 100 m/s, the canister will *not burst*.

62. Let $s_A(t)$ and $s_B(t)$ be the position functions for cars A and B and let $f(t) = s_A(t) - s(t)$. Since A passed B twice, there must be three values of t such that $f(t) = 0$. Then by three applications of Rolle's Theorem (see Exercise 4.2.22), there is a number c such that $f''(c) = 0$. So $s_A''(c) = s_B''(c)$, that is, A and B had equal accelerations at $t = c$. We assume that f is continuous on $[0, T]$ and twice differentiable on $(0, T)$, where T is the total time of the race.

$$\begin{aligned}
 63. (a) I &= \frac{k \cos \theta}{d^2} = \frac{k(h/d)}{d^2} = k \frac{h}{d^3} = k \frac{h}{(\sqrt{40^2 + h^2})^3} = k \frac{h}{(1600 + h^2)^{3/2}} \Rightarrow \\
 \frac{dI}{dh} &= k \frac{(1600 + h^2)^{3/2} - h \cdot \frac{3}{2} (1600 + h^2)^{1/2} \cdot 2h}{[(1600 + h^2)^{3/2}]^2} = \frac{k(1600 + h^2)^{1/2} (1600 + h^2 - 3h^2)}{(1600 + h^2)^3} \\
 &= \frac{k(1600 - 2h^2)}{(1600 + h^2)^{5/2}} \quad [k \text{ is the constant of proportionality}]
 \end{aligned}$$

Set $dI/dh = 0$: $1600 - 2h^2 = 0 \Rightarrow h^2 = 800 \Rightarrow h = \sqrt{800} = 20\sqrt{2}$. By the First Derivative Test, I has a local maximum at $h = 20\sqrt{2} \approx 28$ ft.

(b)

$$\frac{dx}{dt} = 4 \text{ ft/s}$$

$$I = \frac{k \cos \theta}{d^2} = \frac{k[(h-4)/d]}{d^2} = \frac{k(h-4)}{d^3} = \frac{k(h-4)}{[(h-4)^2 + x^2]^{3/2}} = k(h-4)[(h-4)^2 + x^2]^{-3/2}$$

$$\begin{aligned} \frac{dI}{dt} &= \frac{dI}{dx} \cdot \frac{dx}{dt} = k(h-4)\left(-\frac{3}{2}\right)[(h-4)^2 + x^2]^{-5/2} \cdot 2x \cdot \frac{dx}{dt} \\ &= k(h-4)(-3x)[(h-4)^2 + x^2]^{-5/2} \cdot 4 = \frac{-12xk(h-4)}{[(h-4)^2 + x^2]^{5/2}} \end{aligned}$$

$$\left. \frac{dI}{dt} \right|_{x=40} = -\frac{480k(h-4)}{[(h-4)^2 + 1600]^{5/2}}$$

□ PROBLEMS PLUS

- Let $f(x) = \sin x - \cos x$ on $[0, 2\pi]$ since f has period 2π . $f'(x) = \cos x + \sin x = 0 \Leftrightarrow \cos x = -\sin x \Leftrightarrow \tan x = -1 \Leftrightarrow x = \frac{3\pi}{4}$ or $\frac{7\pi}{4}$. Evaluating f at its critical numbers and endpoints, we get $f(0) = -1$, $f(\frac{3\pi}{4}) = \sqrt{2}$, $f(\frac{7\pi}{4}) = -\sqrt{2}$, and $f(2\pi) = -1$. So f has absolute maximum value $\sqrt{2}$ and absolute minimum value $-\sqrt{2}$. Thus, $-\sqrt{2} \leq \sin x - \cos x \leq \sqrt{2} \Rightarrow |\sin x - \cos x| \leq \sqrt{2}$.
- $x^2 y^2 (4 - x^2)(4 - y^2) = x^2(4 - x^2)y^2(4 - y^2) = f(x)f(y)$, where $f(t) = t^2(4 - t^2)$. We will show that $0 \leq f(t) \leq 4$ for $|t| \leq 2$, which gives $0 \leq f(x)f(y) \leq 16$ for $|x| \leq 2$ and $|y| \leq 2$.
 $f(t) = 4t^2 - t^4 \Rightarrow f'(t) = 8t - 4t^3 = 4t(2 - t^2) = 0 \Rightarrow t = 0$ or $\pm\sqrt{2}$.
 $f(0) = 0$, $f(\pm\sqrt{2}) = 2(4 - 2) = 4$, and $f(2) = 0$. So 0 is the absolute minimum value of $f(t)$ on $[-2, 2]$ and 4 is the absolute maximum value of $f(t)$ on $[-2, 2]$. We conclude that $0 \leq f(t) \leq 4$ for $|t| \leq 2$ and hence, $0 \leq f(x)f(y) \leq 4^2$ or $0 \leq x^2(4 - x^2)y^2(4 - y^2) \leq 16$.
- First we show that $x(1 - x) \leq \frac{1}{4}$ for all x . Let $f(x) = x(1 - x) = x - x^2$. Then $f'(x) = 1 - 2x$. This is 0 when $x = \frac{1}{2}$ and $f'(x) > 0$ for $x < \frac{1}{2}$, $f'(x) < 0$ for $x > \frac{1}{2}$, so the absolute maximum of f is $f(\frac{1}{2}) = \frac{1}{4}$. Thus, $x(1 - x) \leq \frac{1}{4}$ for all x .
 Now suppose that the given assertion is false, that is, $a(1 - b) > \frac{1}{4}$ and $b(1 - a) > \frac{1}{4}$. Multiply these inequalities: $a(1 - b)b(1 - a) > \frac{1}{16} \Rightarrow [a(1 - a)][b(1 - b)] > \frac{1}{16}$. But we know that $a(1 - a) \leq \frac{1}{4}$ and $b(1 - b) \leq \frac{1}{4} \Rightarrow [a(1 - a)][b(1 - b)] \leq \frac{1}{16}$. Thus, we have a contradiction, so the given assertion is proved.
- Let $P(a, 1 - a^2)$ be the point of contact. The equation of the tangent line at P is $y - (1 - a^2) = (-2a)(x - a) \Rightarrow y - 1 + a^2 = -2ax + 2a^2 \Rightarrow y = -2ax + a^2 + 1$. To find the x -intercept, put $y = 0$: $2ax = a^2 + 1 \Rightarrow x = \frac{a^2 + 1}{2a}$. To find the y -intercept, put $x = 0$: $y = a^2 + 1$. Therefore, the area of the triangle is $\frac{1}{2} \left(\frac{a^2 + 1}{2a} \right) (a^2 + 1) = \frac{(a^2 + 1)^2}{4a}$. Therefore, we minimize the function $A(a) = \frac{(a^2 + 1)^2}{4a}$, $0 < a \leq 1$.
 $A'(a) = \frac{(4a)2(a^2 + 1)(2a) - (a^2 + 1)^2(4)}{16a^2} = \frac{(a^2 + 1)[4a^2 - (a^2 + 1)]}{4a^2} = \frac{(a^2 + 1)(3a^2 - 1)}{4a^2}$.
 $A'(a) = 0$ when $3a^2 - 1 = 0 \Rightarrow a = \frac{1}{\sqrt{3}}$. $A'(a) < 0$ for $a < \frac{1}{\sqrt{3}}$, $A'(a) > 0$ for $a > \frac{1}{\sqrt{3}}$. So by the First Derivative Test, there is an absolute minimum when $a = \frac{1}{\sqrt{3}}$. The required point is $(\frac{1}{\sqrt{3}}, \frac{2}{3})$ and the corresponding minimum area is $A(\frac{1}{\sqrt{3}}) = \frac{4\sqrt{3}}{9}$.
- Differentiating $x^2 + xy + y^2 = 12$ implicitly with respect to x gives $2x + y + x \frac{dy}{dx} + 2y \frac{dy}{dx} = 0$, so $\frac{dy}{dx} = -\frac{2x + y}{x + 2y}$. At a highest or lowest point, $\frac{dy}{dx} = 0 \Leftrightarrow y = -2x$. Substituting $-2x$ for y in the original equation gives $x^2 + x(-2x) + (-2x)^2 = 12$, so $3x^2 = 12$ and $x = \pm 2$. If $x = 2$, then $y = -2x = -4$, and if $x = -2$ then $y = 4$. Thus, the highest and lowest points are $(-2, 4)$ and $(2, -4)$.
- (a) $V'(t)$ is the rate of change of the volume of the water with respect to time. $H'(t)$ is the rate of change of the height of the water with respect to time. Since the volume and the height are increasing, $V'(t)$ and $H'(t)$ are positive.

(b) $V'(t)$ is constant, so $V''(t)$ is zero (the slope of a constant function is 0).

(c) At first, the height H of the water increases quickly because the tank is narrow. But as the sphere widens, the rate of increase of the height slows down, reaching a minimum at $t = t_2$. Thus, the height is increasing at a decreasing rate on $(0, t_2)$, so its graph is concave downward and $H''(t_1) < 0$. As the sphere narrows for $t > t_2$, the rate of increase of the height begins to increase, and the graph of H is concave upward. Therefore, $H''(t_2) = 0$ and $H''(t_3) > 0$.

$$7. f(x) = \frac{1}{1+|x|} + \frac{1}{1+|x-2|}$$

$$= \begin{cases} \frac{1}{1-x} + \frac{1}{1-(x-2)} & \text{if } x < 0 \\ \frac{1}{1+x} + \frac{1}{1-(x-2)} & \text{if } 0 \leq x < 2 \\ \frac{1}{1+x} + \frac{1}{1+(x-2)} & \text{if } x \geq 2 \end{cases} \Rightarrow f'(x) = \begin{cases} \frac{1}{(1-x)^2} + \frac{1}{(3-x)^2} & \text{if } x < 0 \\ \frac{-1}{(1+x)^2} + \frac{1}{(3-x)^2} & \text{if } 0 < x < 2 \\ \frac{-1}{(1+x)^2} - \frac{1}{(x-1)^2} & \text{if } x > 2 \end{cases}$$

We see that $f'(x) > 0$ for $x < 0$ and $f'(x) < 0$ for $x > 2$. For $0 < x < 2$, we have

$$f'(x) = \frac{1}{(3-x)^2} - \frac{1}{(x+1)^2} = \frac{(x^2 + 2x + 1) - (x^2 - 6x + 9)}{(3-x)^2(x+1)^2} = \frac{8(x-1)}{(3-x)^2(x+1)^2}, \text{ so } f'(x) < 0 \text{ for}$$

$0 < x < 1$, $f'(1) = 0$ and $f'(x) > 0$ for $1 < x < 2$. We have shown that $f'(x) > 0$ for $x < 0$; $f'(x) < 0$ for $0 < x < 1$; $f'(x) > 0$ for $1 < x < 2$; and $f'(x) < 0$ for $x > 2$. Therefore, by the First Derivative Test, the local maxima of f are at $x = 0$ and $x = 2$, where f takes the value $\frac{4}{3}$. Therefore, $\frac{4}{3}$ is the absolute maximum value of f .

8. If $f''(x) > 0$ for all x , then f' is increasing on $(-\infty, \infty)$, so $f'(0)$ must be greater than $f'(-1)$. But $f'(0) = 0 < \frac{1}{2} = f'(-1)$, so such a function cannot exist.

9. $A = (x_1, x_1^2)$ and $B = (x_2, x_2^2)$, where x_1 and x_2 are the solutions of the quadratic equation $x^2 = mx + b$. Let $P = (x, x^2)$ and set $A_1 = (x_1, 0)$, $B_1 = (x_2, 0)$, and $P_1 = (x, 0)$. Let $f(x)$ denote the area of triangle PAB . Then $f(x)$ can be expressed in terms of the areas of three trapezoids as follows:

$$f(x) = \text{area}(A_1ABB_1) - \text{area}(A_1APP_1) - \text{area}(B_1BPP_1)$$

$$= \frac{1}{2}(x_1^2 + x_2^2)(x_2 - x_1) - \frac{1}{2}(x_1^2 + x^2)(x - x_1) - \frac{1}{2}(x^2 + x_2^2)(x_2 - x)$$

After expanding and canceling terms, we get

$$f(x) = \frac{1}{2}(x_2x_1^2 - x_1x_2^2 - x_1^2x + x_1x^2 - x_2x^2 + x_2x_1^2) = \frac{1}{2}[x_1^2(x_2 - x) + x_2^2(x - x_1) + x^2(x_1 - x_2)]$$

$$f'(x) = \frac{1}{2}[-x_1^2 + x_2^2 + 2x(x_1 - x_2)]. \quad f''(x) = \frac{1}{2}[2(x_1 - x_2)] = x_1 - x_2 < 0 \text{ since } x_2 > x_1.$$

$$f'(x) = 0 \Rightarrow 2x(x_1 - x_2) = x_1^2 - x_2^2 \Rightarrow x_P = \frac{1}{2}(x_1 + x_2).$$

$$f(x_P) = \frac{1}{2}(x_1^2[\frac{1}{2}(x_2 - x_1)] + x_2^2[\frac{1}{2}(x_2 - x_1)] + \frac{1}{4}(x_1 + x_2)^2(x_1 - x_2))$$

$$= \frac{1}{2}[\frac{1}{2}(x_2 - x_1)(x_1^2 + x_2^2) - \frac{1}{4}(x_2 - x_1)(x_1 + x_2)^2]$$

$$= \frac{1}{8}(x_2 - x_1)[2(x_1^2 + x_2^2) - (x_1^2 + 2x_1x_2 + x_2^2)]$$

$$= \frac{1}{8}(x_2 - x_1)(x_1^2 - 2x_1x_2 + x_2^2) = \frac{1}{8}(x_2 - x_1)(x_1 - x_2)^2 = \frac{1}{8}(x_2 - x_1)(x_2 - x_1)^2$$

$$= \frac{1}{8}(x_2 - x_1)^3$$

To put this in terms of m and b , we solve the system $y = x_1^2$ and $y = mx_1 + b$, giving us $x_1^2 - mx_1 - b = 0 \Rightarrow x_1 = \frac{1}{2}(m - \sqrt{m^2 + 4b})$. Similarly, $x_2 = \frac{1}{2}(m + \sqrt{m^2 + 4b})$. The area is then $\frac{1}{8}(x_2 - x_1)^3 = \frac{1}{8}(\sqrt{m^2 + 4b})^3$, and is attained at the point $P(x_P, x_P^2) = P(\frac{1}{2}m, \frac{1}{4}m^2)$.

Note: Another way to get an expression for $f(x)$ is to use the formula for an area of a triangle in terms of the coordinates of the vertices: $f(x) = \frac{1}{2}[(x_2x_1^2 - x_1x_2^2) + (x_1x^2 - xx_1^2) + (xx_2^2 - x_2x^2)]$.

10. If $f'(x) < 0$ for all x , $f''(x) > 0$ for $|x| > 1$, $f''(x) < 0$ for $|x| < 1$, and

$\lim_{x \rightarrow \pm\infty} [f(x) + x] = 0$, then f is decreasing everywhere, concave up on

$(-\infty, -1)$ and $(1, \infty)$, concave down on $(-1, 1)$, and approaches the line

$y = -x$ as $x \rightarrow \pm\infty$. An example of such a graph is sketched.

11. $f(x) = (a^2 + a - 6) \cos 2x + (a - 2)x + \cos 1 \Rightarrow f'(x) = -(a^2 + a - 6) \sin 2x + (a - 2)$.

The derivative exists for all x , so the only possible critical points will occur where $f'(x) = 0 \Leftrightarrow$

$2(a - 2)(a + 3) \sin 2x = a - 2 \Leftrightarrow$ either $a = 2$ or $2(a + 3) \sin 2x = 1$, with the latter implying that

$\sin 2x = \frac{1}{2(a + 3)}$. Since the range of $\sin 2x$ is $[-1, 1]$, this equation has no solution whenever either

$\frac{1}{2(a + 3)} < -1$ or $\frac{1}{2(a + 3)} > 1$. Solving these inequalities, we get $-\frac{7}{2} < a < -\frac{5}{2}$.

12. To sketch the region $\{(x, y) \mid 2xy \leq |x - y| \leq x^2 + y^2\}$, we consider two cases.

Case 1: $x \geq y$ This is the case in which (x, y) lies on or below the line $y = x$. The double inequality becomes $2xy \leq x - y \leq x^2 + y^2$. The right-hand inequality holds if and only if $x^2 - x + y^2 + y \geq 0 \Leftrightarrow (x - \frac{1}{2})^2 + (y + \frac{1}{2})^2 \geq \frac{1}{2} \Leftrightarrow (x, y)$ lies on or outside the circle with radius $\frac{1}{\sqrt{2}}$ centered at $(\frac{1}{2}, -\frac{1}{2})$.

The left-hand inequality holds if and only if $2xy - x + y \leq 0 \Leftrightarrow xy - \frac{1}{2}x + \frac{1}{2}y \leq 0 \Leftrightarrow (x + \frac{1}{2})(y - \frac{1}{2}) \leq -\frac{1}{4} \Leftrightarrow (x, y)$ lies on or below the hyperbola $(x + \frac{1}{2})(y - \frac{1}{2}) = -\frac{1}{4}$, which passes through the origin and approaches the lines $y = \frac{1}{2}$ and $x = -\frac{1}{2}$ asymptotically.

Case 2: $y \geq x$ This is the case in which (x, y) lies on or above the line $y = x$. The double inequality becomes $2xy \leq y - x \leq x^2 + y^2$. The right-hand inequality holds if and only if $x^2 + x + y^2 - y \geq 0 \Leftrightarrow (x + \frac{1}{2})^2 + (y - \frac{1}{2})^2 \geq \frac{1}{2} \Leftrightarrow (x, y)$ lies on or outside the circle of radius $\frac{1}{\sqrt{2}}$ centered at $(-\frac{1}{2}, \frac{1}{2})$. The left-hand inequality holds if and only if $2xy + x - y \leq 0 \Leftrightarrow xy + \frac{1}{2}x - \frac{1}{2}y \leq 0 \Leftrightarrow (x - \frac{1}{2})(y + \frac{1}{2}) \leq -\frac{1}{4} \Leftrightarrow (x, y)$ lies on or above the left-hand branch of the hyperbola $(x - \frac{1}{2})(y + \frac{1}{2}) = -\frac{1}{4}$, which passes through the origin and approaches the lines $y = -\frac{1}{2}$ and $x = \frac{1}{2}$ asymptotically. Therefore, the region of interest consists of the points on or above the left branch of the hyperbola $(x - \frac{1}{2})(y + \frac{1}{2}) = -\frac{1}{4}$ that are on or outside the circle

$(x + \frac{1}{2})^2 + (y - \frac{1}{2})^2 = \frac{1}{2}$, together with the points on or below the right branch of the hyperbola $(x + \frac{1}{2})(y - \frac{1}{2}) = -\frac{1}{4}$ that are on or outside the circle $(x - \frac{1}{2})^2 + (y + \frac{1}{2})^2 = \frac{1}{2}$. Note that the inequalities are unchanged when x and y are interchanged, so the region is symmetric about the line $y = x$. So we need only have analyzed case 1 and then reflected that region about the line $y = x$, instead of considering case 2.

13. (a) Let $y = |AD|$, $x = |AB|$, and $1/x = |AC|$, so that $|AB| \cdot |AC| = 1$.

We compute the area $\mathcal{A}$ of $\triangle ABC$ in two ways. First,

$$\mathcal{A} = \frac{1}{2} |AB| |AC| \sin \frac{2\pi}{3} = \frac{1}{2} \cdot 1 \cdot \frac{\sqrt{3}}{2} = \frac{\sqrt{3}}{4}.$$

$$\mathcal{A} = (\text{area of } \triangle ABD) + (\text{area of } \triangle ACD)$$

$$= \frac{1}{2} |AB| |AD| \sin \frac{\pi}{3} + \frac{1}{2} |AD| |AC| \sin \frac{\pi}{3}$$

$$= \frac{1}{2} xy \frac{\sqrt{3}}{2} + \frac{1}{2} y(1/x) \frac{\sqrt{3}}{2} = \frac{\sqrt{3}}{4} y(x + 1/x)$$

Equating the two expressions for the area, we get $\frac{\sqrt{3}}{4} y \left(x + \frac{1}{x} \right) = \frac{\sqrt{3}}{4} \Leftrightarrow y = \frac{1}{x + 1/x} = \frac{x}{x^2 + 1}, x > 0$.

Another method: Use the Law of Sines on the triangles ABD and ABC . In $\triangle ABD$, we have

$$\angle A + \angle B + \angle D = 180^\circ \Leftrightarrow 60^\circ + \alpha + \angle D = 180^\circ \Leftrightarrow \angle D = 120^\circ - \alpha. \text{ Thus,}$$

$$\frac{x}{y} = \frac{\sin(120^\circ - \alpha)}{\sin \alpha} = \frac{\sin 120^\circ \cos \alpha - \cos 120^\circ \sin \alpha}{\sin \alpha} = \frac{\frac{\sqrt{3}}{2} \cos \alpha + \frac{1}{2} \sin \alpha}{\sin \alpha} \Rightarrow \frac{x}{y} = \frac{\sqrt{3}}{2} \cot \alpha + \frac{1}{2},$$

and by a similar argument with $\triangle ABC$, $\frac{\sqrt{3}}{2} \cot \alpha = x^2 + \frac{1}{2}$. Eliminating $\cot \alpha$ gives $\frac{x}{y} = (x^2 + \frac{1}{2}) + \frac{1}{2} \Rightarrow$

$$y = \frac{x}{x^2 + 1}, x > 0.$$

- (b) We differentiate our expression for y with respect to x to find the maximum:

$$\frac{dy}{dx} = \frac{(x^2 + 1) - x(2x)}{(x^2 + 1)^2} = \frac{1 - x^2}{(x^2 + 1)^2} = 0 \text{ when } x = 1. \text{ This indicates a maximum by the First Derivative}$$

Test, since $y'(x) > 0$ for $0 < x < 1$ and $y'(x) < 0$ for $x > 1$, so the maximum value of y is $y(1) = \frac{1}{2}$.

14. (a)

From geometry, two tangents to a circle from a given point have the same length, so $|CF| = |CD|$, $|AE| = |AF|$, and $|BD| = |BE|$. Thus,

$$\begin{aligned} \frac{1}{2}(|BC| + |AC| - |AB|) &= \frac{1}{2}[(|BD| + |DC|) + (|AF| + |FC|) - (|AE| + |EB|)] \\ &= \frac{1}{2}[(|BD| + |CD|) + (|AF| + |CD|) - (|AF| + |BD|)] \\ &= \frac{1}{2}[2|CD|] = |CD| \end{aligned}$$

- (b) Using the result from part (a) and the fact that $a = |BC|$, we have $\tan \theta = \frac{r}{|CD|} \Rightarrow$

$$\frac{r}{\tan \theta} = |CD| = \frac{1}{2}(|AC| + |BC| - |AB|) = \frac{1}{2}(a \cos 2\theta + a - a \sin 2\theta) \Leftrightarrow$$

$$\begin{aligned} r &= \frac{1}{2} a \tan \theta (2 \cos^2 \theta - 1 + 1 - 2 \sin \theta \cos \theta) \\ &= \frac{1}{2} a (2 \sin \theta \cos \theta - 2 \sin^2 \theta) && \text{[in terms of } \theta] \\ &= \frac{1}{2} a (\sin 2\theta + \cos 2\theta - 1) && \text{[in terms of } 2\theta] \end{aligned}$$

- (c) We differentiate r with respect to θ and set $dr/d\theta$ equal to 0 to find the maximum values:

$$\begin{aligned} dr/d\theta &= \frac{1}{2} a (2 \cos 2\theta - 2 \sin 2\theta) = a (\cos 2\theta - \sin 2\theta). \text{ Since } 0 < \theta < \frac{\pi}{4}, dr/d\theta = 0 \Leftrightarrow \cos 2\theta = \sin 2\theta \\ \Leftrightarrow 1 &= \tan 2\theta \Leftrightarrow 2\theta = \frac{\pi}{4} \Leftrightarrow \theta = \frac{\pi}{8}. \text{ This gives a maximum by the First Derivative Test, since} \end{aligned}$$

$dr/d\theta > 0$ for $0 < \theta < \frac{\pi}{8}$, and $dr/d\theta < 0$ for $\frac{\pi}{8} < \theta < \frac{\pi}{4}$. The maximum value is

$$r\left(\frac{\pi}{8}\right) = \frac{1}{2}a\left(\sin \frac{\pi}{4} + \cos \frac{\pi}{4} - 1\right) = \frac{1}{2}(\sqrt{2} - 1)a \approx 0.207a.$$

15. (a) $A = \frac{1}{2}bh$ with $\sin \theta = h/c$, so $A = \frac{1}{2}bc \sin \theta$. But A is a constant, so differentiating this equation with respect to t , we

$$\text{get } \frac{dA}{dt} = 0 = \frac{1}{2} \left[bc \cos \theta \frac{d\theta}{dt} + b \frac{dc}{dt} \sin \theta + \frac{db}{dt} c \sin \theta \right]$$

$$\Rightarrow bc \cos \theta \frac{d\theta}{dt} = -\sin \theta \left[b \frac{dc}{dt} + c \frac{db}{dt} \right] \Rightarrow \frac{d\theta}{dt} = -\tan \theta \left[\frac{1}{c} \frac{dc}{dt} + \frac{1}{b} \frac{db}{dt} \right].$$

- (b) We use the Law of Cosines to get the length of side a in terms of those of b and c , and then

$$\text{we differentiate implicitly with respect to } t: a^2 = b^2 + c^2 - 2bc \cos \theta \Rightarrow$$

$$2a \frac{da}{dt} = 2b \frac{db}{dt} + 2c \frac{dc}{dt} - 2 \left[bc(-\sin \theta) \frac{d\theta}{dt} + b \frac{dc}{dt} \cos \theta + \frac{db}{dt} c \cos \theta \right] \Rightarrow$$

$$\frac{da}{dt} = \frac{1}{a} \left(b \frac{db}{dt} + c \frac{dc}{dt} + bc \sin \theta \frac{d\theta}{dt} - b \frac{dc}{dt} \cos \theta - c \frac{db}{dt} \cos \theta \right). \text{ Now we substitute our value of } a \text{ from the}$$

Law of Cosines and the value of $d\theta/dt$ from part (a), and simplify (primes signify differentiation by t):

$$\begin{aligned} \frac{da}{dt} &= \frac{bb' + cc' + bc \sin \theta [-\tan \theta (c'/c + b'/b)] - (bc' + cb')(\cos \theta)}{\sqrt{b^2 + c^2 - 2bc \cos \theta}} \\ &= \frac{bb' + cc' - [\sin^2 \theta (bc' + cb') + \cos^2 \theta (bc' + cb')]/\cos \theta}{\sqrt{b^2 + c^2 - 2bc \cos \theta}} = \frac{bb' + cc' - (bc' + cb')\sec \theta}{\sqrt{b^2 + c^2 - 2bc \cos \theta}} \end{aligned}$$

16. Let $x = |AE|$, $y = |AF|$ as shown. The area $\mathcal{A}$ of the $\triangle AEF$ is $\mathcal{A} = \frac{1}{2}xy$. We need to find a relationship between x and y , so that we can take the derivative $d\mathcal{A}/dx$ and then find the maximum and minimum areas. Now let A' be the point on which A ends up after the fold has been performed, and let P be the intersection of AA' and EF . Note that AA' is perpendicular to EF since we are reflecting A through the line EF to get to A' , and that $|AP| = |PA'|$ for the same reason. But $|AA'| = 1$, since AA' is a radius of the circle. Since $|AP| + |PA'| = |AA'|$,

we have $|AP| = \frac{1}{2}$. Another way to express the area of the triangle is

$$\mathcal{A} = \frac{1}{2}|EF||AP| = \frac{1}{2}\sqrt{x^2 + y^2}\left(\frac{1}{2}\right) = \frac{1}{4}\sqrt{x^2 + y^2}. \text{ Equating the two expressions for } \mathcal{A}, \text{ we get}$$

$$\frac{1}{2}xy = \frac{1}{4}\sqrt{x^2 + y^2} \Rightarrow 4x^2y^2 = x^2 + y^2 \Rightarrow y^2(4x^2 - 1) = x^2 \Rightarrow y = x/\sqrt{4x^2 - 1}.$$

(Note that we could also have derived this result from the similarity of $\triangle A'PE$ and $\triangle A'FE$; that is,

$$\frac{|A'P|}{|PE|} = \frac{|A'F|}{|A'E|} \Rightarrow \frac{\frac{1}{2}}{\sqrt{x^2 - (\frac{1}{2})^2}} = \frac{y}{x} \Rightarrow y = \frac{\frac{1}{2}x}{\sqrt{4x^2 - 1}/2} = \frac{x}{\sqrt{4x^2 - 1}}.)$$

Now we can substitute for y and calculate $\frac{d\mathcal{A}}{dx}$: $\mathcal{A} = \frac{1}{2} \frac{x^2}{\sqrt{4x^2 - 1}} \Rightarrow$

$$\frac{dA}{dx} = \frac{1}{2} \left[\frac{\sqrt{4x^2 - 1}(2x) - x^2(\frac{1}{2})(4x^2 - 1)^{-1/2}(8x)}{4x^2 - 1} \right]. \text{ This is 0 when } 2x\sqrt{4x^2 - 1} - 4x^3(4x^2 - 1)^{-1/2} = 0$$

$$\Leftrightarrow 2x(4x^2 - 1)^{-1/2} [(4x^2 - 1) - 2x^2] = 0 \Rightarrow (4x^2 - 1) - 2x^2 = 0 \quad (x > 0) \Leftrightarrow 2x^2 = 1 \Rightarrow$$

$x = \frac{1}{\sqrt{2}}$. So this is one possible value for an extremum. We must also test the endpoints of the interval over

which x ranges. The largest value that x can attain is 1, and the smallest value of x occurs when $y = 1 \Leftrightarrow$

$$1 = x/\sqrt{4x^2 - 1} \Leftrightarrow x^2 = 4x^2 - 1 \Leftrightarrow 3x^2 = 1 \Leftrightarrow x = \frac{1}{\sqrt{3}}. \text{ This will give the same value of } A \text{ as will}$$

$x = 1$, since the geometric situation is the same (reflected through the line $y = x$). We calculate

$$A\left(\frac{1}{\sqrt{2}}\right) = \frac{1}{2} \frac{(1/\sqrt{2})^2}{\sqrt{4(1/\sqrt{2})^2 - 1}} = \frac{1}{4} = 0.25, \text{ and } A(1) = \frac{1}{2} \frac{1^2}{\sqrt{4(1)^2 - 1}} = \frac{1}{2\sqrt{3}} \approx 0.29. \text{ So the maximum area}$$

$$\text{is } A(1) = A\left(\frac{1}{\sqrt{3}}\right) = \frac{1}{2\sqrt{3}} \text{ and the minimum area is } A\left(\frac{1}{\sqrt{2}}\right) = \frac{1}{4}.$$

Another method: Use the angle θ (see diagram above) as a variable:

$$A = \frac{1}{2}xy = \frac{1}{2}\left(\frac{1}{2}\sec\theta\right)\left(\frac{1}{2}\csc\theta\right) = \frac{1}{8\sin\theta\cos\theta} = \frac{1}{4\sin 2\theta}. A \text{ is minimized when } \sin 2\theta \text{ is maximal, that is,}$$

$$\text{when } \sin 2\theta = 1 \Rightarrow 2\theta = \frac{\pi}{2} \Rightarrow \theta = \frac{\pi}{4}. \text{ Also note that } A'E = x = \frac{1}{2}\sec\theta \leq 1 \Rightarrow \sec\theta \leq 2 \Rightarrow$$

$$\cos\theta \geq \frac{1}{2} \Rightarrow \theta \leq \frac{\pi}{3}, \text{ and similarly, } A'F = y = \frac{1}{2}\csc\theta \leq 1 \Rightarrow \csc\theta \leq 2 \Rightarrow \sin\theta \leq \frac{1}{2} \Rightarrow \theta \geq \frac{\pi}{6}.$$

$$\text{As above, we find that } A \text{ is maximized at these endpoints: } A\left(\frac{\pi}{6}\right) = \frac{1}{4\sin\frac{\pi}{3}} = \frac{1}{2\sqrt{3}} = \frac{1}{4\sin\frac{2\pi}{3}} = A\left(\frac{\pi}{3}\right); \text{ and}$$

$$\text{minimized at } \theta = \frac{\pi}{4}: A\left(\frac{\pi}{4}\right) = \frac{1}{4\sin\frac{\pi}{2}} = \frac{1}{4}.$$

$$17. \text{ (a) Distance} = \text{rate} \times \text{time, so time} = \text{distance/rate. } T_1 = \frac{D}{c_1},$$

$$T_2 = \frac{2|PR|}{c_1} + \frac{|RS|}{c_2} = \frac{2h\sec\theta}{c_1} + \frac{D - 2h\tan\theta}{c_2}, T_3 = \frac{2\sqrt{h^2 + D^2/4}}{c_1} = \frac{\sqrt{4h^2 + D^2}}{c_1}.$$

$$\text{(b) } \frac{dT_2}{d\theta} = \frac{2h}{c_1} \cdot \sec\theta \tan\theta - \frac{2h}{c_2} \sec^2\theta = 0 \text{ when } 2h\sec\theta \left(\frac{1}{c_1} \tan\theta - \frac{1}{c_2} \sec\theta \right) = 0 \Rightarrow$$

$$\frac{1}{c_1} \frac{\sin\theta}{\cos\theta} - \frac{1}{c_2} \frac{1}{\cos\theta} = 0 \Rightarrow \frac{\sin\theta}{c_1 \cos\theta} = \frac{1}{c_2 \cos\theta} \Rightarrow \sin\theta = \frac{c_1}{c_2}. \text{ The First Derivative Test shows that}$$

this gives a minimum.

$$\text{(c) Using part (a) with } D = 1 \text{ and } T_1 = 0.26, \text{ we have } T_1 = \frac{D}{c_1} \Rightarrow$$

$$c_1 = \frac{1}{0.26} \approx 3.85 \text{ km/s. } T_3 = \frac{\sqrt{4h^2 + D^2}}{c_1} \Rightarrow 4h^2 + D^2 = T_3^2 c_1^2 \Rightarrow$$

$$h = \frac{1}{2} \sqrt{T_3^2 c_1^2 - D^2} = \frac{1}{2} \sqrt{(0.34)^2 (1/0.26)^2 - 1^2} \approx 0.42 \text{ km. To find } c_2, \text{ we use } \sin\theta = \frac{c_1}{c_2} \text{ from part (b)}$$

and $T_2 = \frac{2h \sec \theta}{c_1} + \frac{D - 2h \tan \theta}{c_2}$ from part (a). From the figure,

$$\sin \theta = \frac{c_1}{c_2} \Rightarrow \sec \theta = \frac{c_2}{\sqrt{c_2^2 - c_1^2}} \text{ and } \tan \theta = \frac{c_1}{\sqrt{c_2^2 - c_1^2}}, \text{ so}$$

$$T_2 = \frac{2hc_2}{c_1 \sqrt{c_2^2 - c_1^2}} + \frac{D \sqrt{c_2^2 - c_1^2} - 2hc_1}{c_2 \sqrt{c_2^2 - c_1^2}}.$$

Using the values for T_2 [given as 0.32], h , c_1 , and D , we can graph

$$Y_1 = T_2 \text{ and } Y_2 = \frac{2hc_2}{c_1 \sqrt{c_2^2 - c_1^2}} + \frac{D \sqrt{c_2^2 - c_1^2} - 2hc_1}{c_2 \sqrt{c_2^2 - c_1^2}} \text{ and find their intersection points. Doing so gives us}$$

$c_2 \approx 4.10$ and 7.66 , but if $c_2 = 4.10$, then $\theta = \arcsin(c_1/c_2) \approx 69.6^\circ$, which implies that point S is to the left of point R in the diagram. So $c_2 = 7.66$ km/s.

18. A straight line intersects the curve $y = f(x) = x^4 + cx^3 + 12x^2 - 5x + 2$ in four distinct points if and only if the graph of f has two inflection points. $f'(x) = 4x^3 + 3cx^2 + 24x - 5$ and $f''(x) = 12x^2 + 6cx + 24$.

$$f''(x) = 0 \Leftrightarrow x = \frac{-6c \pm \sqrt{(6c)^2 - 4(12)(24)}}{2(12)}. \text{ There are two distinct roots for } f''(x) = 0 \text{ (and hence two}$$

inflection points) if and only if the discriminant is positive; that is, $36c^2 - 1152 > 0 \Leftrightarrow c^2 > 32 \Leftrightarrow$

$|c| > \sqrt{32}$. Thus, the desired values of c are $c < -4\sqrt{2}$ or $c > 4\sqrt{2}$.

19.

Let $a = |EF|$ and $b = |BF|$ as shown in the figure.

Since $\ell = |BF| + |FD|$, $|FD| = \ell - b$. Now

$$\begin{aligned} |ED| &= |EF| + |FD| = a + \ell - b \\ &= \sqrt{r^2 - x^2} + \ell - \sqrt{(d-x)^2 + a^2} \\ &= \sqrt{r^2 - x^2} + \ell - \sqrt{(d-x)^2 + (\sqrt{r^2 - x^2})^2} \\ &= \sqrt{r^2 - x^2} + \ell - \sqrt{d^2 - 2dx + x^2 + r^2 - x^2} \end{aligned}$$

$$\text{Let } f(x) = \sqrt{r^2 - x^2} + \ell - \sqrt{d^2 + r^2 - 2dx}.$$

$$f'(x) = \frac{1}{2}(r^2 - x^2)^{-1/2}(-2x) - \frac{1}{2}(d^2 + r^2 - 2dx)^{-1/2}(-2d) = \frac{-x}{\sqrt{r^2 - x^2}} + \frac{d}{\sqrt{d^2 + r^2 - 2dx}}.$$

$$f'(x) = 0 \Rightarrow \frac{x}{\sqrt{r^2 - x^2}} = \frac{d}{\sqrt{d^2 + r^2 - 2dx}} \Rightarrow \frac{x^2}{r^2 - x^2} = \frac{d^2}{d^2 + r^2 - 2dx} \Rightarrow$$

$$d^2x^2 + r^2x^2 - 2dx^3 = d^2r^2 - d^2x^2 \Rightarrow 0 = 2dx^3 - 2d^2x^2 - r^2x^2 + d^2r^2 \Rightarrow$$

$$0 = 2dx^2(x - d) - r^2(x^2 - d^2) \Rightarrow 0 = 2dx^2(x - d) - r^2(x + d)(x - d) \Rightarrow$$

$$0 = (x - d)[2dx^2 - r^2(x + d)]$$

But $d > r > x$, so $x \neq d$. Thus, we solve $2dx^2 - r^2x - dr^2 = 0$ for x :

$$x = \frac{-(-r^2) \pm \sqrt{(-r^2)^2 - 4(2d)(-dr^2)}}{2(2d)} = \frac{r^2 \pm \sqrt{r^4 + 8d^2r^2}}{4d}. \text{ Because } \sqrt{r^4 + 8d^2r^2} > r^2, \text{ the "negative"}$$

can be discarded. Thus,

$$\begin{aligned} x &= \frac{r^2 + \sqrt{r^4 + 8d^2r^2}}{4d} = \frac{r^2 + r\sqrt{r^2 + 8d^2}}{4d} \quad (r > 0) \\ &= \frac{r}{4d} \left(r + \sqrt{r^2 + 8d^2} \right) \end{aligned}$$

The maximum value of $|ED|$ occurs at this value of x .

20.

Let $a = \overline{CD}$ denote the distance from the center C of the base to the midpoint D of a side of the base.

$$\text{Since } \triangle PQR \text{ is similar to } \triangle DCR, \frac{a}{h} = \frac{r}{\sqrt{h(h-2r)}} \Rightarrow a = \frac{rh}{\sqrt{h(h-2r)}} = r \frac{\sqrt{h}}{\sqrt{h-2r}}.$$

Let b denote one-half the length of a side of the base. The area A of the base is

$$A = 8(\text{area of } \triangle CDE) = 8\left(\frac{1}{2}ab\right) = 4a\left(a \tan \frac{\pi}{4}\right) = 4a^2.$$

$$\text{The volume of the pyramid is } V = \frac{1}{3}Ah = \frac{1}{3}(4a^2)h = \frac{4}{3}\left(r \frac{\sqrt{h}}{\sqrt{h-2r}}\right)^2 h = \frac{4}{3}r^2 \frac{h^2}{h-2r}, \text{ with domain } h > 2r.$$

$$\text{Now } \frac{dV}{dh} = \frac{4}{3}r^2 \cdot \frac{(h-2r)(2h) - h^2(1)}{(h-2r)^2} = \frac{4}{3}r^2 \frac{h^2 - 4hr}{(h-2r)^2} = \frac{4}{3}r^2 \frac{h(h-4r)}{(h-2r)^2}$$

$$\begin{aligned} \text{and } \frac{d^2V}{dh^2} &= \frac{4}{3}r^2 \cdot \frac{(h-2r)^2(2h-4r) - (h^2-4hr)(2)(h-2r)(1)}{[(h-2r)^2]^2} \\ &= \frac{4}{3}r^2 \cdot \frac{2(h-2r)[(h^2-4hr+4r^2) - (h^2-4hr)]}{(h-2r)^2} \\ &= \frac{8}{3}r^2 \cdot \frac{4r^2}{(h-2r)^3} = \frac{32}{3}r^4 \cdot \frac{1}{(h-2r)^3}. \end{aligned}$$

The first derivative is equal to zero for $h = 4r$ and the second derivative is positive for $h > 2r$, so the volume of the pyramid is minimized when $h = 4r$.

To extend our solution to a regular n -gon, we make the following changes:

- (1) the number of sides of the base is n
- (2) the number of triangles in the base is $2n$
- (3) $\angle DCE = \frac{\pi}{n}$
- (4) $b = a \tan \frac{\pi}{n}$

We then obtain the following results:

$$A = na^2 \tan \frac{\pi}{n}, V = \frac{nr^2}{3} \cdot \tan\left(\frac{\pi}{n}\right) \cdot \frac{h^2}{h-2r}, \frac{dV}{dh} = \frac{nr^2}{3} \cdot \tan\left(\frac{\pi}{n}\right) \cdot \frac{h(h-4r)}{(h-2r)^2}, \text{ and}$$

$\frac{d^2V}{dh^2} = \frac{8nr^4}{3} \cdot \tan\left(\frac{\pi}{n}\right) \cdot \frac{1}{(h-2r)^3}$. Notice that the answer, $h = 4r$, is independent of the number of sides of the

base of the polygon!

21. $V = \frac{4}{3}\pi r^3 \Leftrightarrow \frac{dV}{dt} = 4\pi r^2 \frac{dr}{dt}$. But $\frac{dV}{dt}$ is proportional to the surface area, so $\frac{dV}{dt} = k \cdot 4\pi r^2$ for some

constant k . Therefore, $4\pi r^2 \frac{dr}{dt} = k \cdot 4\pi r^2 \Leftrightarrow \frac{dr}{dt} = k = \text{constant}$. An antiderivative of k with respect to t is kt , so $r = kt + C$. When $t = 0$, the radius r must equal the original radius r_0 , so $C = r_0$, and $r = kt + r_0$. To find

$$k \text{ we use the fact that when } t = 3, r = 3k + r_0 \text{ and } V = \frac{1}{2}V_0 \rightarrow \frac{4}{3}\pi(3k + r_0)^3 = \frac{1}{2} \cdot \frac{4}{3}\pi r_0^3 \Rightarrow$$

$$(3k + r_0)^3 = \frac{1}{2}r_0^3 \quad \Rightarrow \quad 3k + r_0 = \frac{1}{\sqrt[3]{2}}r_0 \quad \Rightarrow \quad k = \frac{1}{3}r_0\left(\frac{1}{\sqrt[3]{2}} - 1\right). \text{ Since } r = kt + r_0,$$

$$r = \frac{1}{3}r_0\left(\frac{1}{\sqrt[3]{2}} - 1\right)t + r_0. \text{ When the snowball has melted completely we have } r = 0 \Rightarrow$$

$$\frac{1}{3}r_0\left(\frac{1}{\sqrt[3]{2}} - 1\right)t + r_0 = 0 \text{ which gives } t = \frac{3\sqrt[3]{2}}{\sqrt[3]{2} - 1}. \text{ Hence, it takes } \frac{3\sqrt[3]{2}}{\sqrt[3]{2} - 1} - 3 = \frac{3}{\sqrt[3]{2} - 1} \approx 11 \text{ h } 33 \text{ min}$$

longer.

- 22.** By ignoring the bottom hemisphere of the initial spherical bubble, we can rephrase the problem as follows: Prove that the maximum height of a stack of n hemispherical bubbles is $\sqrt{n}$ if the radius of the bottom hemisphere is 1. We proceed by induction. The case $n = 1$ is obvious since $\sqrt{1}$ is the height of the first hemisphere. Suppose the assertion is true for $n = k$ and let's suppose we have $k + 1$ hemispherical bubbles forming a stack of maximum height. Suppose the second hemisphere (counting from the bottom) has radius r . Then by our induction hypothesis

(scaled to the setting of a bottom hemisphere of radius r), the height of the stack formed by the top k bubbles is $\sqrt{k}r$. (If it were shorter, then the total stack of $k+1$ bubbles wouldn't have maximum height.)

The height of the whole stack is $H(r) = \sqrt{k}r + \sqrt{1-r^2}$. (See the figure.)

We want to choose r so as to maximize $H(r)$. Note that $0 < r < 1$. We calculate

$$H'(r) = \sqrt{k} - \frac{r}{\sqrt{1-r^2}} \text{ and } H''(r) = \frac{-1}{(1-r^2)^{3/2}}. \quad H'(r) = 0 \Leftrightarrow$$

$$r^2 = k(1-r^2) \Leftrightarrow (k+1)r^2 = k \Leftrightarrow r = \sqrt{\frac{k}{k+1}}. \text{ This is the only}$$

critical number in $(0, 1)$ and it represents a local maximum (hence an absolute

maximum) since $H''(r) < 0$ on $(0, 1)$. When $r = \sqrt{\frac{k}{k+1}}$,

$$H(r) = \sqrt{k} \frac{\sqrt{k}}{\sqrt{k+1}} + \sqrt{1 - \frac{k}{k+1}} = \frac{k}{\sqrt{k+1}} + \frac{1}{\sqrt{k+1}} = \sqrt{k+1}. \text{ Thus, the assertion is true for } n = k+1$$

when it is true for $n = k$. By induction, it is true for all positive integers n .

Note: In general, a maximally tall stack of n hemispherical bubbles consists of bubbles with

$$\text{radii } 1, \sqrt{\frac{n-1}{n}}, \sqrt{\frac{n-2}{n}}, \dots, \sqrt{\frac{2}{n}}, \sqrt{\frac{1}{n}}.$$

5 □ INTEGRALS

5.1 Areas and Distances

1. (a) Since f is *increasing*, we can obtain a *lower* estimate by using *left* endpoints. We are instructed to use five rectangles, so $n = 5$.

$$\begin{aligned} L_5 &= \sum_{i=1}^5 f(x_{i-1}) \Delta x \quad [\Delta x = \frac{b-a}{n} = \frac{10-0}{5} = 2] \\ &= f(x_0) \cdot 2 + f(x_1) \cdot 2 + f(x_2) \cdot 2 + f(x_3) \cdot 2 + f(x_4) \cdot 2 \\ &= 2[f(0) + f(2) + f(4) + f(6) + f(8)] \\ &\approx 2(1 + 3 + 4.3 + 5.4 + 6.3) = 2(20) = 40 \end{aligned}$$

Since f is *increasing*, we can obtain an *upper* estimate by using *right* endpoints.

$$\begin{aligned} R_5 &= \sum_{i=1}^5 f(x_i) \Delta x \\ &= 2[f(x_1) + f(x_2) + f(x_3) + f(x_4) + f(x_5)] \\ &= 2[f(2) + f(4) + f(6) + f(8) + f(10)] \\ &\approx 2(3 + 4.3 + 5.4 + 6.3 + 7) = 2(26) = 52 \end{aligned}$$

Comparing R_5 to L_5 , we see that we have added the area of the rightmost upper rectangle, $f(10) \cdot 2$, to the sum and subtracted the area of the leftmost lower rectangle, $f(0) \cdot 2$, from the sum.

$$\begin{aligned} \text{(b) } L_{10} &= \sum_{i=1}^{10} f(x_{i-1}) \Delta x \quad [\Delta x = \frac{10-0}{10} = 1] \\ &= 1[f(x_0) + f(x_1) + \cdots + f(x_9)] \\ &= f(0) + f(1) + \cdots + f(9) \\ &\approx 1 + 2.1 + 3 + 3.7 + 4.3 + 4.9 + 5.4 + 5.8 + 6.3 + 6.7 \\ &= 43.2 \end{aligned}$$

$$\begin{aligned} R_{10} &= \sum_{i=1}^{10} f(x_i) \Delta x = f(1) + f(2) + \cdots + f(10) \\ &= L_{10} + 1 \cdot f(10) - 1 \cdot f(0) \quad \left[\begin{array}{l} \text{add rightmost upper rectangle,} \\ \text{subtract leftmost lower rectangle} \end{array} \right] \\ &= 43.2 + 7 - 1 = 49.2 \end{aligned}$$

$$\begin{aligned}
 2. (a) (i) L_6 &= \sum_{i=1}^6 f(x_{i-1}) \Delta x \quad [\Delta x = \frac{12-0}{6} = 2] \\
 &= 2[f(x_0) + f(x_1) + f(x_2) + f(x_3) + f(x_4) + f(x_5)] \\
 &= 2[f(0) + f(2) + f(4) + f(6) + f(8) + f(10)] \\
 &\approx 2(9 + 8.8 + 8.2 + 7.3 + 5.9 + 4.1) \\
 &= 2(43.3) = 86.6
 \end{aligned}$$

$$\begin{aligned}
 (ii) R_6 &= L_6 + 2 \cdot f(12) - 2 \cdot f(0) \\
 &\approx 86.6 + 2(1) - 2(9) = 70.6
 \end{aligned}$$

[Add area of rightmost lower rectangle
and subtract area of leftmost upper rectangle.]

$$\begin{aligned}
 (iii) M_6 &= \sum_{i=1}^6 f(x_i^*) \Delta x \\
 &= 2[f(1) + f(3) + f(5) + f(7) + f(9) + f(11)] \\
 &\approx 2(8.9 + 8.5 + 7.8 + 6.6 + 5.1 + 2.8) \\
 &= 2(39.7) = 79.4
 \end{aligned}$$

(b) Since f is decreasing, we obtain an *overestimate* by using *left* endpoints; that is, L_6 .

(c) Since f is decreasing, we obtain an *underestimate* by using *right* endpoints; that is, R_6 .

(d) M_6 gives the best estimate, since the area of each rectangle appears to be closer to the true area than the overestimates and underestimates in L_6 and R_6 .

$$\begin{aligned}
 3. (a) R_4 &= \sum_{i=1}^4 f(x_i) \Delta x \quad [\Delta x = \frac{5-1}{4} = 1] \\
 &= f(x_1) \cdot 1 + f(x_2) \cdot 1 + f(x_3) \cdot 1 + f(x_4) \cdot 1 \\
 &= f(2) + f(3) + f(4) + f(5) \\
 &= \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} = \frac{77}{60} = 1.28\bar{3}
 \end{aligned}$$

Since f is decreasing on $[1, 5]$, an *underestimate* is obtained by using the *right* endpoint approximation, R_4 .

$$\begin{aligned}
 (b) L_4 &= \sum_{i=1}^4 f(x_{i-1}) \Delta x \\
 &= f(1) + f(2) + f(3) + f(4) \\
 &= 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} = \frac{25}{12} = 2.08\bar{3}
 \end{aligned}$$

L_4 is an overestimate. Alternatively, we could just add the area of the leftmost upper rectangle and subtract the area of the rightmost lower rectangle; that is, $L_4 = R_4 + f(1) \cdot 1 - f(5) \cdot 1$.

$$\begin{aligned}
 4. (a) R_5 &= \sum_{i=1}^5 f(x_i) \Delta x \quad [\Delta x = \frac{5-0}{5} = 1] \\
 &= f(x_1) \cdot 1 + f(x_2) \cdot 1 + f(x_3) \cdot 1 + f(x_4) \cdot 1 + f(x_5) \cdot 1 \\
 &= f(1) + f(2) + f(3) + f(4) + f(5) \\
 &= 24 + 21 + 16 + 9 + 0 = 70
 \end{aligned}$$

Since f is decreasing on $[0, 5]$, R_5 is an underestimate.

$$\begin{aligned}
 (b) L_5 &= \sum_{i=1}^5 f(x_{i-1}) \Delta x \\
 &= f(0) + f(1) + f(2) + f(3) + f(4) \\
 &= 25 + 24 + 21 + 16 + 9 = 95
 \end{aligned}$$

L_5 is an overestimate.

$$5. (a) f(x) = 1 + x^2 \text{ and } \Delta x = \frac{2 - (-1)}{3} = 1 \Rightarrow$$

$$R_3 = 1 \cdot f(0) + 1 \cdot f(1) + 1 \cdot f(2) = 1 \cdot 1 + 1 \cdot 2 + 1 \cdot 5 = 8.$$

$$\Delta x = \frac{2 - (-1)}{6} = 0.5 \Rightarrow$$

$$\begin{aligned}
 R_6 &= 0.5[f(-0.5) + f(0) + f(0.5) + f(1) + f(1.5) + f(2)] \\
 &= 0.5(1.25 + 1 + 1.25 + 2 + 3.25 + 5) \\
 &= 0.5(13.75) = 6.875
 \end{aligned}$$

$$(b) L_3 = 1 \cdot f(-1) + 1 \cdot f(0) + 1 \cdot f(1) = 1 \cdot 2 + 1 \cdot 1 + 1 \cdot 2 = 5$$

$$\begin{aligned}
 L_6 &= 0.5[f(-1) + f(-0.5) + f(0) + f(0.5) + f(1) + f(1.5)] \\
 &= 0.5(2 + 1.25 + 1 + 1.25 + 2 + 3.25) \\
 &= 0.5(10.75) = 5.375
 \end{aligned}$$

$$(c) M_3 = 1 \cdot f(-0.5) + 1 \cdot f(0.5) + 1 \cdot f(1.5)$$

$$= 1 \cdot 1.25 + 1 \cdot 1.25 + 1 \cdot 3.25 = 5.75$$

$$\begin{aligned}
 M_6 &= 0.5[f(-0.75) + f(-0.25) + f(0.25) \\
 &\quad + f(0.75) + f(1.25) + f(1.75)] \\
 &= 0.5(1.5625 + 1.0625 + 1.0625 + 1.5625 + 2.5625 + 4.0625) \\
 &= 0.5(11.875) = 5.9375
 \end{aligned}$$

(d) M_6 appears to be the best estimate.

6. (a)

(b) $f(x) = 1/(1+x^2)$ and $\Delta x = \frac{2-(-2)}{4} = 1 \Rightarrow$

$$\begin{aligned} \text{(i) } R_4 &= \sum_{i=1}^4 f(x_i) \Delta x \\ &= f(-1) \cdot 1 + f(0) \cdot 1 \\ &\quad + f(1) \cdot 1 + f(2) \cdot 1 \\ &= \frac{1}{2} + 1 + \frac{1}{2} + \frac{1}{5} = \frac{11}{5} = 2.2 \end{aligned}$$

$$\begin{aligned} \text{(ii) } M_4 &= \sum_{i=1}^4 f(\bar{x}_i) \Delta x \quad [\bar{x}_i = \frac{1}{2}(x_{i-1} + x_i)] \\ &= f(-1.5) \cdot 1 + f(-0.5) \cdot 1 \\ &\quad + f(0.5) \cdot 1 + f(1.5) \cdot 1 \\ &= \frac{4}{13} + \frac{4}{5} + \frac{4}{5} + \frac{4}{13} = \frac{144}{65} \approx 2.2154 \end{aligned}$$

(c) $n = 8$, so $\Delta x = \frac{2-(-2)}{8} = \frac{1}{2}$.

$$\begin{aligned} R_8 &= \frac{1}{2} [f(-1.5) + f(-1) + f(-0.5) + f(0) + f(0.5) + f(1) + f(1.5) + f(2)] \\ &= \frac{1}{2} \left[\frac{4}{13} + \frac{1}{2} + \frac{4}{5} + 1 + \frac{4}{5} + \frac{1}{2} + \frac{4}{13} + \frac{1}{5} \right] = \frac{287}{130} \approx 2.2077 \end{aligned}$$

$$\begin{aligned} M_8 &= \frac{1}{2} [f(-1.75) + f(-1.25) + f(-0.75) + f(-0.25) + f(0.25) + f(0.75) + f(1.25) + f(1.75)] \\ &= \frac{1}{2} \left[2 \left(\frac{16}{65} + \frac{16}{41} + \frac{16}{25} + \frac{16}{17} \right) \right] \approx 2.2176 \end{aligned}$$

7. Here is one possible algorithm (ordered sequence of operations) for calculating the sums:

1 Let $SUM = 0$, $X_MIN = 0$, $X_MAX = \pi$, $N = 10$ (or 30 or 50, depending on which sum we are calculating), $DELTA_X = (X_MAX - X_MIN)/N$, and $RIGHT_ENDPOINT = X_MIN + DELTA_X$.

2 Repeat steps 2a, 2b in sequence until $RIGHT_ENDPOINT > X_MAX$.

2a Add $\sin(RIGHT_ENDPOINT)$ to SUM .

2b Add $DELTA_X$ to $RIGHT_ENDPOINT$.

At the end of this procedure, $(DELTA_X) \cdot (SUM)$ is equal to the answer we are looking for. We find that

$$R_{10} = \frac{\pi}{10} \sum_{i=1}^{10} \sin\left(\frac{i\pi}{10}\right) \approx 1.9835, R_{30} = \frac{\pi}{30} \sum_{i=1}^{30} \sin\left(\frac{i\pi}{30}\right) \approx 1.9982, \text{ and } R_{50} = \frac{\pi}{50} \sum_{i=1}^{50} \sin\left(\frac{i\pi}{50}\right) \approx 1.9993.$$

It appears that the exact area is 2.

Shown below is program SUMRIGHT and its output from a TI-83 Plus calculator. To generalize the program, we have input (rather than assigned) values for Xmin, Xmax, and N. Also, the function, $\sin x$, is assigned to Y_1 , enabling us to evaluate any right sum merely by changing Y_1 and running the program.

```
PROGRAM: SUMRIGHT
:0→S

8. We can use the algorithm from Exercise 7 with $X_MIN = 1$, $X_MAX = 2$, and $1 / (\text{RIGHT_ENDPOINT})^2$ instead

of $\sin(\text{RIGHT_ENDPOINT})$ in step 2a. We find that $R_{10} = \frac{1}{10} \sum_{i=1}^{10} \frac{1}{(1+i/10)^2} \approx 0.4640$,

$R_{30} = \frac{1}{30} \sum_{i=1}^{30} \frac{1}{(1+i/30)^2} \approx 0.4877$, and $R_{50} = \frac{1}{50} \sum_{i=1}^{50} \frac{1}{(1+i/50)^2} \approx 0.4926$. It appears that the exact area is $\frac{1}{2}$.

9. In Maple, we have to perform a number of steps before getting a numerical answer. After

loading the student package [command: `with(student);`] we use the command

`left_sum:=leftsum(x^(1/2),x=1..4,10 [or 30, or 50]);` which gives us the expression in summation notation. To get a numerical approximation to the sum, we use `evalf(left_sum);`. Mathematica does not have

a special command for these sums, so we must type them in manually. For example, the first left sum is given by

$(3/10) * \text{Sum}[\text{Sqrt}[1+3(i-1)/10], \{i, 1, 10\}]$, and we use the `N` command on the resulting output to get a numerical approximation.

In Derive, we use the `LEFT_RIEMANN` command to get the left sums, but must define the right sums ourselves.

(We can define a new function using `LEFT_RIEMANN` with k ranging from 1 to n instead of from 0 to $n-1$.)

(a) With $f(x) = \sqrt{x}$, $1 \leq x \leq 4$, the left sums are of the form $L_n = \frac{3}{n} \sum_{i=1}^n \sqrt{1 + \frac{3(i-1)}{n}}$. Specifically,

$L_{10} \approx 4.5148$, $L_{30} \approx 4.6165$, and $L_{50} \approx 4.6366$. The right sums are of the form $R_n = \frac{3}{n} \sum_{i=1}^n \sqrt{1 + \frac{3i}{n}}$.

Specifically, $R_{10} \approx 4.8148$, $R_{30} \approx 4.7165$, and $R_{50} \approx 4.6966$.

- (b) In Maple, we use the `leftbox` and `rightbox` commands (with the same arguments as `leftsum` and `rightsum` above) to generate the graphs.

left endpoints, $n = 10$ left endpoints, $n = 30$ left endpoints, $n = 50$ right endpoints, $n = 10$ right endpoints, $n = 30$ right endpoints, $n = 50$

- (c) We know that since $\sqrt{x}$ is an increasing function on $(1, 4)$, all of the left sums are smaller than the actual area, and all of the right sums are larger than the actual area. Since the left sum with $n = 50$ is about $4.637 > 4.6$ and the right sum with $n = 50$ is about $4.697 < 4.7$, we conclude that $4.6 < L_{50} < \text{exact area} < R_{50} < 4.7$, so the exact area is between 4.6 and 4.7.

10. See the solution to Exercise 9 for the CAS commands for evaluating the sums.

- (a) With $f(x) = \sin(\sin x)$, $0 \leq x \leq \frac{\pi}{2}$, the left sums are of the form $L_n = \frac{\pi}{2n} \sum_{i=1}^n \sin\left(\sin \frac{\pi(i-1)}{2n}\right)$. In particular, $L_{10} \approx 0.8251$, $L_{30} \approx 0.8710$, and $L_{50} \approx 0.8799$. The right sums are of the form

$$R_n = \frac{\pi}{2n} \sum_{i=1}^n \sin\left(\sin \frac{\pi i}{2n}\right). \text{ In particular, } R_{10} \approx 0.9573, R_{30} \approx 0.9150, \text{ and } R_{50} \approx 0.9064.$$

- (b) In Maple, we use the `leftbox` and `rightbox` commands (with the same arguments as `leftsum` and `rightsum` above) to generate the graphs.

left endpoints, $n = 10$ left endpoints, $n = 30$ left endpoints, $n = 50$

right endpoints, $n = 10$ right endpoints, $n = 30$ right endpoints, $n = 50$

(c) We know that since $\sin(\sin x)$ is an increasing function on $(0, \frac{\pi}{2})$ [this is true because its derivative, $-\cos(\sin x)(-\cos x)$, is positive on that interval], all of the left sums are smaller than the actual area, and all of the right sums are larger than the actual area. Since the left sum with $n = 50$ is about $0.8799 > 0.87$ and the right sum with $n = 50$ is about $0.9064 < 0.91$, we conclude that $0.87 < L_{50} < \text{exact area} < R_{50} < 0.91$, so the exact area is between 0.87 and 0.91.

- 11.** Since v is an increasing function, L_6 will give us a lower estimate and R_6 will give us an upper estimate.

$$L_6 = (0 \text{ ft/s})(0.5 \text{ s}) + (6.2)(0.5) + (10.8)(0.5) + (14.9)(0.5) + (18.1)(0.5) + (19.4)(0.5) \\ = 0.5(69.4) = 34.7 \text{ ft}$$

$$R_6 = 0.5(6.2 + 10.8 + 14.9 + 18.1 + 19.4 + 20.2) = 0.5(89.6) = 44.8 \text{ ft}$$

- 12.** (a) $d \approx L_5 = (30 \text{ ft/s})(12 \text{ s}) + 28 \cdot 12 + 25 \cdot 12 + 22 \cdot 12 + 24 \cdot 12$

$$= (30 + 28 + 25 + 22 + 24) \cdot 12 = 129 \cdot 12 = 1548 \text{ ft}$$

(b) $d \approx R_5 = (28 + 25 + 22 + 24 + 27) \cdot 12 = 126 \cdot 12 = 1512$ ft

(c) The estimates are neither lower nor upper estimates since v is neither an increasing nor a decreasing function of t .

- 13.** Lower estimate for oil leakage: $R_5 = (7.6 + 6.8 + 6.2 + 5.7 + 5.3)(2) = (31.6)(2) = 63.2$ L.

Upper estimate for oil leakage: $L_5 = (8.7 + 7.6 + 6.8 + 6.2 + 5.7)(2) = (35)(2) = 70$ L.

- 14.** We can find an upper estimate by using the final velocity for each time interval. Thus, the distance d traveled after 62 seconds can be approximated by

$$d = \sum_{i=1}^6 v(t_i) \Delta t_i = (185 \text{ ft/s})(10 \text{ s}) + 319 \cdot 5 + 447 \cdot 5 + 742 \cdot 12 + 1325 \cdot 27 + 1445 \cdot 3 = 54,694 \text{ ft}$$

- 15.** For a decreasing function, using left endpoints gives us an overestimate and using right endpoints results in an underestimate. We will use M_6 to get an estimate. $\Delta t = 1$, so

$$M_6 = 1[v(0.5) + v(1.5) + v(2.5) + v(3.5) + v(4.5) + v(5.5)] \\ \approx 55 + 40 + 28 + 18 + 10 + 4 = 155 \text{ ft}$$

For a very rough check on the above calculation, we can draw a line from $(0, 70)$ to $(6, 0)$ and calculate the area of the triangle: $\frac{1}{2}(70)(6) = 210$. This is clearly an overestimate, so our midpoint estimate of 155 is reasonable.

- 16.** For an increasing function, using left endpoints gives us an underestimate and using right endpoints results in an overestimate. We will use M_6 to get an estimate. $\Delta t = \frac{30-0}{6} = 5 \text{ s} = \frac{5}{3600} \text{ h} = \frac{1}{720} \text{ h}$.

$$M_6 = \frac{1}{720} [v(2.5) + v(7.5) + v(12.5) + v(17.5) + v(22.5) + v(27.5)]$$

$$= \frac{1}{720} (31.25 + 66 + 88 + 103.5 + 113.75 + 119.25) = \frac{1}{720} (521.75) \approx 0.725 \text{ km}$$

For a very rough check on the above calculation, we can draw a line from $(0, 0)$ to $(30, 120)$ and calculate the area

of the triangle: $\frac{1}{2}(30)(120) = 1800$. Divide by 3600 to get 0.5, which is clearly an underestimate, making our midpoint estimate of 0.725 seem reasonable. Of course, answers will vary due to different readings of the graph.

17. $f(x) = \sqrt[4]{x}$, $1 \leq x \leq 16$. $\Delta x = (16 - 1)/n = 15/n$ and $x_i = 1 + i \Delta x = 1 + 15i/n$.

$$A = \lim_{n \rightarrow \infty} R_n = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \sqrt[4]{1 + \frac{15i}{n}} \cdot \frac{15}{n}.$$

18. $f(x) = 1 + x^4$, $2 \leq x \leq 5$. $\Delta x = (5 - 2)/n = 3/n$ and $x_i = 2 + i \Delta x = 2 + 3i/n$.

$$A = \lim_{n \rightarrow \infty} R_n = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \left[1 + \left(2 + \frac{3i}{n} \right)^4 \right] \cdot \frac{3}{n}.$$

19. $f(x) = x \cos x$, $0 \leq x \leq \frac{\pi}{2}$. $\Delta x = (\frac{\pi}{2} - 0)/n = \frac{\pi}{2n}$ and $x_i = 0 + i \Delta x = \frac{\pi}{2n} i$.

$$A = \lim_{n \rightarrow \infty} R_n = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{i\pi}{2n} \cos\left(\frac{i\pi}{2n}\right) \cdot \frac{\pi}{2n}.$$

20. $\lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{2}{n} \left(5 + \frac{2i}{n} \right)^{10}$ can be interpreted as the area of the region lying under the graph of $y = (5 + x)^{10}$ on the

interval $[0, 2]$, since for $y = (5 + x)^{10}$ on $[0, 2]$ with $\Delta x = \frac{2-0}{n} = \frac{2}{n}$, $x_i = 0 + i \Delta x = \frac{2i}{n}$, and $x_i^* = x_i$, the

expression for the area is $A = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i^*) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \left(5 + \frac{2i}{n} \right)^{10} \frac{2}{n}$. Note that the answer is not unique.

We could use $y = x^{10}$ on $[5, 7]$ or, in general, $y = ((5 - n) + x)^{10}$ on $[n, n + 2]$.

21. $\lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{\pi}{4n} \tan \frac{i\pi}{4n}$ can be interpreted as the area of the region lying under the graph of $y = \tan x$ on the interval

$[0, \frac{\pi}{4}]$, since for $y = \tan x$ on $[0, \frac{\pi}{4}]$ with $\Delta x = \frac{\pi/4 - 0}{n} = \frac{\pi}{4n}$, $x_i = 0 + i \Delta x = \frac{i\pi}{4n}$, and $x_i^* = x_i$, the

expression for the area is $A = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i^*) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \tan\left(\frac{i\pi}{4n}\right) \frac{\pi}{4n}$. Note that this answer is not unique,

since the expression for the area is the same for the function $y = \tan(x - k\pi)$ on the interval $[k\pi, k\pi + \frac{\pi}{4}]$, where k is any integer.

22. (a) $\Delta x = \frac{1-0}{n} = \frac{1}{n}$ and $x_i = 0 + i \Delta x = \frac{i}{n}$. $A = \lim_{n \rightarrow \infty} R_n = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \left(\frac{i}{n} \right)^3 \cdot \frac{1}{n}$.

$$(b) \lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{i^3}{n^3} \cdot \frac{1}{n} = \lim_{n \rightarrow \infty} \frac{1}{n^4} \sum_{i=1}^n i^3 = \lim_{n \rightarrow \infty} \frac{1}{n^4} \left[\frac{n(n+1)}{2} \right]^2 = \lim_{n \rightarrow \infty} \frac{(n+1)^2}{4n^2} = \frac{1}{4} \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n} \right)^2 = \frac{1}{4}$$

23. (a) $y = f(x) = x^5$. $\Delta x = \frac{2-0}{n} = \frac{2}{n}$ and $x_i = 0 + i \Delta x = \frac{2i}{n}$.

$$A = \lim_{n \rightarrow \infty} R_n = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \left(\frac{2i}{n} \right)^5 \cdot \frac{2}{n} = \lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{32i^5}{n^5} \cdot \frac{2}{n} = \lim_{n \rightarrow \infty} \frac{64}{n^6} \sum_{i=1}^n i^5.$$

$$(b) \sum_{i=1}^n i^5 \stackrel{\text{CAS}}{=} \frac{n^2(n+1)^2(2n^2+2n-1)}{12}$$

$$(c) \lim_{n \rightarrow \infty} \frac{64}{n^6} \cdot \frac{n^2(n+1)^2(2n^2+2n-1)}{12} = \frac{64}{12} \lim_{n \rightarrow \infty} \frac{(n^2+2n+1)(2n^2+2n-1)}{n^2 \cdot n^2} \\ = \frac{16}{3} \lim_{n \rightarrow \infty} \left(1 + \frac{2}{n} + \frac{1}{n^2} \right) \left(2 + \frac{2}{n} - \frac{1}{n^2} \right) = \frac{16}{3} \cdot 1 \cdot 2 = \frac{32}{3}$$

24. (a) $y = f(x) = x^4 + 5x^2 + x$, $2 \leq x \leq 7 \Rightarrow \Delta x = \frac{7-2}{n} = \frac{5}{n}$, $x_i = 2 + i\Delta x = 2 + \frac{5i}{n} \Rightarrow$

$$A = \lim_{n \rightarrow \infty} R_n = \lim_{n \rightarrow \infty} \frac{5}{n} \sum_{i=1}^n \left[\left(2 + \frac{5i}{n}\right)^4 + 5 \left(2 + \frac{5i}{n}\right)^2 + \left(2 + \frac{5i}{n}\right) \right]$$

(b) $R_n = \frac{5}{n} \cdot \frac{4723n^4 + 7845n^3 + 3475n^2 - 125}{6n^3}$

(c) $A = \lim_{n \rightarrow \infty} R_n = \frac{23,615}{6} = 3935.8\bar{3}$

25. $y = f(x) = \cos x$. $\Delta x = \frac{b-0}{n} = \frac{b}{n}$ and $x_i = 0 + i\Delta x = \frac{bi}{n}$.

$$A = \lim_{n \rightarrow \infty} R_n = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \cos\left(\frac{bi}{n}\right) \cdot \frac{b}{n} \stackrel{\text{CAS}}{=} \lim_{n \rightarrow \infty} \left[\frac{b \sin\left(b\left(\frac{1}{2n} + 1\right)\right)}{2n \sin\left(\frac{b}{2n}\right)} - \frac{b}{2n} \right] \stackrel{\text{CAS}}{=} \sin b$$

If $b = \frac{\pi}{2}$, then $A = \sin \frac{\pi}{2} = 1$. The value 1 is the *exact* area, whereas the value obtained in Example 3(b), 1.006, is just an *approximation*.

26. (a)

The diagram shows one of the n congruent triangles, $\triangle AOB$, with central angle $2\pi/n$. O is the center of the circle and AB is one of the sides of the polygon. Radius OC is drawn so as to bisect $\angle AOB$. It follows that OC intersects AB at right angles and bisects AB . Thus, $\triangle AOB$ is divided into two right triangles with legs of length

$$\frac{1}{2}(AB) = r \sin(\pi/n) \text{ and } r \cos(\pi/n).$$

$\triangle AOB$ has area $2 \cdot \frac{1}{2} [r \sin(\pi/n)] [r \cos(\pi/n)] = r^2 \sin(\pi/n) \cos(\pi/n) = \frac{1}{2} r^2 \sin(2\pi/n)$, so

$$A_n = n \cdot \text{area}(\triangle AOB) = \frac{1}{2} n r^2 \sin(2\pi/n).$$

(b) To use Equation 3.5.2, $\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} = 1$, we need to have the same expression in the denominator as we have in the argument of the sine function—in this case, $2\pi/n$.

$$\lim_{n \rightarrow \infty} A_n = \lim_{n \rightarrow \infty} \frac{1}{2} n r^2 \sin(2\pi/n) = \lim_{n \rightarrow \infty} \frac{1}{2} n r^2 \frac{\sin(2\pi/n)}{2\pi/n} \cdot \frac{2\pi}{n} = \lim_{n \rightarrow \infty} \frac{\sin(2\pi/n)}{2\pi/n} \pi r^2. \text{ Let } \theta = \frac{2\pi}{n}.$$

$$\text{Then as } n \rightarrow \infty, \theta \rightarrow 0, \text{ so } \lim_{n \rightarrow \infty} \frac{\sin(2\pi/n)}{2\pi/n} \pi r^2 = \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} \pi r^2 = (1) \pi r^2 = \pi r^2.$$

5.2 The Definite Integral

1. $R_4 = \sum_{i=1}^4 f(x_i) \Delta x$ [$x_i^* = x_i$ is a right endpoint and $\Delta x = 0.5$]
 $= 0.5 [f(0.5) + f(1) + f(1.5) + f(2)]$ [$f(x) = 2 - x^2$]
 $= 0.5 [1.75 + 1 + (-0.25) + (-2)]$
 $= 0.5(0.5) = 0.25$

The Riemann sum represents the sum of the areas of the two rectangles above the x -axis minus the sum of the areas of the two rectangles below the x -axis; that is, the *net area* of the rectangles with respect to the x -axis.

$$\begin{aligned}
 2. L_6 &= \sum_{i=1}^6 f(x_{i-1}) \Delta x \quad [x_i^* = x_{i-1} \text{ is a left endpoint and } \Delta x = 0.5] \\
 &= 0.5 [f(0) + f(0.5) + f(1) \\
 &\quad + f(1.5) + f(2) + f(2.5)] \quad [f(x) = 3x - 7] \\
 &= 0.5[-7 + (-5.5) + (-4) + (-2.5) + (-1) + 0.5] \\
 &= 0.5(-19.5) = -9.75
 \end{aligned}$$

The Riemann sum represents the area of the rectangle above the x -axis minus the area of the five rectangles below the x -axis.

$$\begin{aligned}
 3. M_5 &= \sum_{i=1}^5 f(\bar{x}_i) \Delta x \quad [x_i^* = \bar{x}_i = \frac{1}{2}(x_{i-1} + x_i) \text{ is a midpoint and } \Delta x = 1] \\
 &= 1 [f(1.5) + f(2.5) + f(3.5) \\
 &\quad + f(4.5) + f(5.5)] \quad [f(x) = \sqrt{x} - 2] \\
 &\approx -0.856759
 \end{aligned}$$

The Riemann sum represents the sum of the areas of the two rectangles above the x -axis minus the sum of the areas of the three rectangles below the x -axis.

$$\begin{aligned}
 4. (a) R_6 &= \sum_{i=1}^6 f(x_i) \Delta x \quad [x_i^* = x_i \text{ is a right endpoint and } \Delta x = 0.5] \\
 &= 0.5 [f(0.5) + f(1) + f(1.5) + f(2) \\
 &\quad + f(2.5) + f(3)] \quad [f(x) = x - 2 \sin 2x] \\
 &\approx 5.353254
 \end{aligned}$$

The Riemann sum represents the sum of the areas of the four rectangles above the x -axis minus the sum of the areas of the two rectangles below the x -axis.

$$\begin{aligned}
 (b) M_6 &= \sum_{i=1}^6 f(\bar{x}_i) \Delta x \quad [x_i^* = \bar{x}_i \text{ is a midpoint and } \Delta x = 0.5] \\
 &= 0.5 [f(0.25) + f(0.75) + f(1.25) + f(1.75) \\
 &\quad + f(2.25) + f(2.75)] \quad [f(x) = x - 2 \sin 2x] \\
 &\approx 4.458461
 \end{aligned}$$

The Riemann sum represents the sum of the areas of the four rectangles above the x -axis minus the sum of the areas of the two rectangles below the x -axis.

$$5. \Delta x = (b - a)/n = (8 - 0)/4 = 8/4 = 2.$$

(a) Using the right endpoints to approximate $\int_0^8 f(x) dx$, we have

$$\sum_{i=1}^4 f(x_i) \Delta x = 2[f(2) + f(4) + f(6) + f(8)] \approx 2[1 + 2 + (-2) + 1] = 4.$$

(b) Using the left endpoints to approximate $\int_0^8 f(x) dx$, we have

$$\sum_{i=1}^4 f(x_{i-1}) \Delta x = 2[f(0) + f(2) + f(4) + f(6)] \approx 2[2 + 1 + 2 + (-2)] = 6.$$

(c) Using the midpoint of each subinterval to approximate $\int_0^8 f(x) dx$, we have

$$\sum_{i=1}^4 f(\bar{x}_i) \Delta x = 2[f(1) + f(3) + f(5) + f(7)] \approx 2[3 + 2 + 1 + (-1)] = 10.$$

6. (a) Using the right endpoints to approximate $\int_{-3}^3 g(x) dx$, we have

$$\begin{aligned} \sum_{i=1}^6 g(x_i) \Delta x &= 1[g(-2) + g(-1) + g(0) + g(1) + g(2) + g(3)] \\ &\approx 1 - 0.5 - 1.5 - 1.5 - 0.5 + 2.5 = -0.5 \end{aligned}$$

(b) Using the left endpoints to approximate $\int_{-3}^3 g(x) dx$, we have

$$\begin{aligned} \sum_{i=1}^6 g(x_{i-1}) \Delta x &= 1[g(-3) + g(-2) + g(-1) + g(0) + g(1) + g(2)] \\ &\approx 2 + 1 - 0.5 - 1.5 - 1.5 - 0.5 = -1 \end{aligned}$$

(c) Using the midpoint of each subinterval to approximate $\int_{-3}^3 g(x) dx$, we have

$$\begin{aligned} \sum_{i=1}^6 g(\bar{x}_i) \Delta x &= 1[g(-2.5) + g(-1.5) + g(-0.5) + g(0.5) + g(1.5) + g(2.5)] \\ &\approx 1.5 + 0 - 1 - 1.75 - 1 + 0.5 = -1.75 \end{aligned}$$

7. Since f is increasing, $L_5 \leq \int_0^{25} f(x) dx \leq R_5$.

$$\begin{aligned} \text{Lower estimate} = L_5 &= \sum_{i=1}^5 f(x_{i-1}) \Delta x = 5[f(0) + f(5) + f(10) + f(15) + f(20)] \\ &= 5(-42 - 37 - 25 - 6 + 15) = 5(-95) = -475 \end{aligned}$$

$$\begin{aligned} \text{Upper estimate} = R_5 &= \sum_{i=1}^5 f(x_i) \Delta x = 5[f(5) + f(10) + f(15) + f(20) + f(25)] \\ &= 5(-37 - 25 - 6 + 15 + 36) = 5(-17) = -85 \end{aligned}$$

8. (a) Using the right endpoints to approximate $\int_0^6 f(x) dx$, we have

$$\sum_{i=1}^3 f(x_i) \Delta x = 2[f(2) + f(4) + f(6)] = 2(8.3 + 2.3 - 10.5) = 0.2$$

(b) Using the left endpoints to approximate $\int_0^6 f(x) dx$, we have

$$\sum_{i=1}^3 f(x_{i-1}) \Delta x = 2[f(0) + f(2) + f(4)] = 2(9.3 + 8.3 + 2.3) = 39.8$$

(c) Using the midpoint of each interval to approximate $\int_0^6 f(x) dx$, we have

$$\sum_{i=1}^3 f(\bar{x}_i) \Delta x = 2[f(1) + f(3) + f(5)] = 2(9.0 + 6.5 - 7.6) = 15.8.$$

The estimate using the right endpoints must be less than $\int_0^6 f(x) dx$, since if we take x_i^* to be the right endpoint x_i of each interval, then $f(x_i) \leq f(x)$ for all x on $[x_{i-1}, x_i]$, which implies that $f(x_i) \Delta x \leq \int_{x_{i-1}}^{x_i} f(x) dx$, and so

the sum $\sum_{i=1}^3 [f(x_i) \Delta x] \leq \sum_{i=1}^3 \left[\int_{x_{i-1}}^{x_i} f(x) dx \right] = \int_0^6 f(x) dx$. Similarly, if we take x_i^* to be the left endpoint x_{i-1}

of each interval, then $f(x_{i-1}) \geq f(x)$ for all x on $[x_{i-1}, x_i]$, and so $\sum_{i=1}^3 [f(x_{i-1}) \Delta x] \geq \int_0^6 f(x) dx$. We cannot

say anything about the midpoint estimate.

9. $\Delta x = (10 - 2)/4 = 2$, so the endpoints are 2, 4, 6, 8, and 10, and the midpoints are 3, 5, 7, and 9. The Midpoint Rule gives

$$\int_2^{10} \sqrt{x^3 + 1} \, dx \approx \sum_{i=1}^4 f(\bar{x}_i) \Delta x = 2(\sqrt{3^3 + 1} + \sqrt{5^3 + 1} + \sqrt{7^3 + 1} + \sqrt{9^3 + 1}) \approx 124.1644.$$

10. $\Delta x = (\pi - 0)/6 = \frac{\pi}{6}$, so the endpoints are 0, $\frac{\pi}{6}$, $\frac{2\pi}{6}$, $\frac{3\pi}{6}$, $\frac{4\pi}{6}$, $\frac{5\pi}{6}$, and $\frac{6\pi}{6}$, and the midpoints are $\frac{\pi}{12}$, $\frac{3\pi}{12}$, $\frac{5\pi}{12}$, $\frac{7\pi}{12}$, $\frac{9\pi}{12}$, and $\frac{11\pi}{12}$. The Midpoint Rule gives

$$\int_0^{\pi} \sec(x/3) \, dx \approx \sum_{i=1}^6 f(\bar{x}_i) \Delta x = \frac{\pi}{6} \left(\sec \frac{\pi}{36} + \sec \frac{3\pi}{36} + \sec \frac{5\pi}{36} + \sec \frac{7\pi}{36} + \sec \frac{9\pi}{36} + \sec \frac{11\pi}{36} \right) \approx 3.9379.$$

11. $\Delta x = (1 - 0)/5 = 0.2$, so the endpoints are 0, 0.2, 0.4, 0.6, 0.8, and 1, and the midpoints are 0.1, 0.3, 0.5, 0.7, and 0.9. The Midpoint Rule gives

$$\int_0^1 \sin(x^2) \, dx \approx \sum_{i=1}^5 f(\bar{x}_i) \Delta x = 0.2 [\sin(0.1)^2 + \sin(0.3)^2 + \sin(0.5)^2 + \sin(0.7)^2 + \sin(0.9)^2] \approx 0.3084.$$

12. $\Delta x = \frac{5-1}{4} = 1$, so the endpoints are 1, 2, 3, 4, and 5, and the midpoints are 1.5, 2.5, 3.5, and 4.5. The Midpoint Rule gives

$$\int_1^5 \frac{x-1}{x+1} \, dx \approx \sum_{i=1}^4 f(\bar{x}_i) \Delta x = 1 \left[\frac{1.5-1}{1.5+1} + \frac{2.5-1}{2.5+1} + \frac{3.5-1}{3.5+1} + \frac{4.5-1}{4.5+1} \right] \approx 1.8205.$$

13. In Maple, we use the command `with(student)`; to load the sum and box commands, then

`m:=middlesum(sin(x^2), x=0..1, 5)`; which gives us the sum in summation notation, then

`M:=evalf(m)`; which gives $M_5 \approx 0.30843908$, confirming the result of Exercise 11. The command

`middlebox(sin(x^2), x=0..1, 5)` generates the graph. Repeating for $n = 10$ and $n = 20$ gives

$M_{10} \approx 0.30981629$ and $M_{20} \approx 0.31015563$.

14. See the solution to Exercise 5.1.7 for a possible algorithm to calculate the sums. With $\Delta x = (1 - 0)/100 = 0.01$ and subinterval endpoints 1, 1.01, 1.02, ..., 1.99, 2, we calculate that the left Riemann sum is

$$L_{100} = \sum_{i=1}^{100} \sin(x_{i-1}^2) \Delta x \approx 0.30607, \text{ and the right Riemann sum is } R_{100} = \sum_{i=1}^{100} \sin(x_i^2) \Delta x \approx 0.31448.$$

Since $f(x) = \sin(x^2)$ is an increasing function, we must have $L_{100} \leq \int_0^1 \sin(x^2) \, dx \leq R_{100}$, so

$0.306 < L_{100} \leq \int_0^1 \sin(x^2) \, dx \leq R_{100} < 0.315$. Therefore, the approximate value $0.3084 \approx 0.31$ in Exercise 11 must be accurate to two decimal places.

15. We'll create the table of values to approximate $\int_0^\pi \sin x \, dx$ by using the program in the solution to Exercise 5.1.7 with $Y_1 = \sin x$, $X_{\min} = 0$, $X_{\max} = \pi$, and $n = 5, 10, 50$, and 100 .

The values of R_n appear to be approaching 2.

n	R_n
5	1.933766
10	1.983524
50	1.999342
100	1.999836

16. $\int_0^2 \sqrt{1+x^4} \, dx$ with $n = 5, 10, 50$, and 100 .

n	L_n	R_n
5	3.080614	4.329856
10	3.354110	3.978731
50	3.591540	3.716464
100	3.622383	3.684845

The value of the integral lies between 3.622 and 3.685. Note that

$f(x) = \sqrt{1+x^4}$ is increasing on $(0, 2)$. We cannot make a similar statement for $\int_{-1}^2 \sqrt{1+x^4} \, dx$ since f is decreasing on $(-1, 0)$.

17. On $[0, \pi]$, $\lim_{n \rightarrow \infty} \sum_{i=1}^n x_i \sin x_i \Delta x = \int_0^\pi x \sin x \, dx$.
18. On $[1, 5]$, $\lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{x_i}{1+x_i} \Delta x = \int_1^5 \frac{x}{1+x} \, dx$.
19. On $[1, 8]$, $\lim_{n \rightarrow \infty} \sum_{i=1}^n \sqrt{2x_i^* + (x_i^*)^2} \Delta x = \int_1^8 \sqrt{2x+x^2} \, dx$.
20. On $[0, 2]$, $\lim_{n \rightarrow \infty} \sum_{i=1}^n [4 - 3(x_i^*)^2 + 6(x_i^*)^5] \Delta x = \int_0^2 (4 - 3x^2 + 6x^5) \, dx$.
21. Note that $\Delta x = \frac{5 - (-1)}{n} = \frac{6}{n}$ and $x_i = -1 + i \Delta x = -1 + \frac{6i}{n}$.

$$\begin{aligned}
 \int_{-1}^5 (1+3x) \, dx &= \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \left[1 + 3 \left(-1 + \frac{6i}{n} \right) \right] \frac{6}{n} \\
 &= \lim_{n \rightarrow \infty} \frac{6}{n} \sum_{i=1}^n \left[-2 + \frac{18i}{n} \right] = \lim_{n \rightarrow \infty} \frac{6}{n} \left[\sum_{i=1}^n (-2) + \sum_{i=1}^n \frac{18i}{n} \right] \\
 &= \lim_{n \rightarrow \infty} \frac{6}{n} \left[-2n + \frac{18}{n} \sum_{i=1}^n i \right] = \lim_{n \rightarrow \infty} \frac{6}{n} \left[-2n + \frac{18}{n} \cdot \frac{n(n+1)}{2} \right] \\
 &= \lim_{n \rightarrow \infty} \left[-12 + \frac{108}{n^2} \cdot \frac{n(n+1)}{2} \right] = \lim_{n \rightarrow \infty} \left[-12 + 54 \frac{n+1}{n} \right] \\
 &= \lim_{n \rightarrow \infty} \left[-12 + 54 \left(1 + \frac{1}{n} \right) \right] = -12 + 54 \cdot 1 = 42
 \end{aligned}$$

$$\begin{aligned}
22. \int_1^4 (x^2 + 2x - 5) dx &= \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x \quad [\Delta x = 3/n \text{ and } x_i = 1 + 3i/n] \\
&= \lim_{n \rightarrow \infty} \sum_{i=1}^n \left[\left(1 + \frac{3i}{n}\right)^2 + 2\left(1 + \frac{3i}{n}\right) - 5 \right] \left(\frac{3}{n}\right) \\
&= \lim_{n \rightarrow \infty} \frac{3}{n} \left[\sum_{i=1}^n \left(1 + \frac{6i}{n} + \frac{9i^2}{n^2} + 2 + \frac{6i}{n} - 5\right) \right] \\
&= \lim_{n \rightarrow \infty} \frac{3}{n} \left[\sum_{i=1}^n \left(\frac{9}{n^2} \cdot i^2 + \frac{12}{n} \cdot i - 2\right) \right] \\
&= \lim_{n \rightarrow \infty} \frac{3}{n} \left[\frac{9}{n^2} \sum_{i=1}^n i^2 + \frac{12}{n} \sum_{i=1}^n i - \sum_{i=1}^n 2 \right] \\
&= \lim_{n \rightarrow \infty} \left(\frac{27}{n^3} \cdot \frac{n(n+1)(2n+1)}{6} + \frac{36}{n^2} \cdot \frac{n(n+1)}{2} - \frac{6}{n} \cdot n \right) \\
&= \lim_{n \rightarrow \infty} \left(\frac{9}{2} \cdot \frac{n+1}{n} \cdot \frac{2n+1}{n} + 18 \cdot \frac{n+1}{n} - 6 \right) \\
&= \lim_{n \rightarrow \infty} \left[\frac{9}{2} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right) + 18 \left(1 + \frac{1}{n}\right) - 6 \right] = \frac{9}{2} \cdot 1 \cdot 2 + 18 \cdot 1 - 6 = 21
\end{aligned}$$

23. Note that $\Delta x = \frac{2-0}{n} = \frac{2}{n}$ and $x_i = 0 + i \Delta x = \frac{2i}{n}$.

$$\begin{aligned}
\int_0^2 (2 - x^2) dx &= \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \left(2 - \frac{4i^2}{n^2}\right) \left(\frac{2}{n}\right) \\
&= \lim_{n \rightarrow \infty} \frac{2}{n} \left[\sum_{i=1}^n 2 - \frac{4}{n^2} \sum_{i=1}^n i^2 \right] = \lim_{n \rightarrow \infty} \frac{2}{n} \left(2n - \frac{4}{n^2} \sum_{i=1}^n i^2 \right) \\
&= \lim_{n \rightarrow \infty} \left[4 - \frac{8}{n^3} \cdot \frac{n(n+1)(2n+1)}{6} \right] = \lim_{n \rightarrow \infty} \left(4 - \frac{4}{3} \cdot \frac{n+1}{n} \cdot \frac{2n+1}{n} \right) \\
&= \lim_{n \rightarrow \infty} \left[4 - \frac{4}{3} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right) \right] = 4 - \frac{4}{3} \cdot 1 \cdot 2 = \frac{4}{3}
\end{aligned}$$

$$\begin{aligned}
24. \int_0^5 (1 + 2x^3) dx &= \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x \quad [\Delta x = 5/n \text{ and } x_i = 5i/n] \\
&= \lim_{n \rightarrow \infty} \sum_{i=1}^n \left(1 + 2 \cdot \frac{125i^3}{n^3}\right) \left(\frac{5}{n}\right) = \lim_{n \rightarrow \infty} \frac{5}{n} \left[\sum_{i=1}^n 1 + \frac{250}{n^3} \sum_{i=1}^n i^3 \right] \\
&= \lim_{n \rightarrow \infty} \frac{5}{n} \left(1 \cdot n + \frac{250}{n^3} \sum_{i=1}^n i^3 \right) = \lim_{n \rightarrow \infty} \left[5 + \frac{1250}{n^4} \cdot \frac{n^2(n+1)^2}{4} \right] \\
&= \lim_{n \rightarrow \infty} \left[5 + 312.5 \cdot \frac{(n+1)^2}{n^2} \right] = \lim_{n \rightarrow \infty} \left[5 + 312.5 \left(1 + \frac{1}{n}\right)^2 \right] \\
&= 5 + 312.5 = 317.5
\end{aligned}$$

25. Note that $\Delta x = \frac{2-1}{n} = \frac{1}{n}$ and $x_i = 1 + i\Delta x = 1 + i(1/n) = 1 + i/n$.

$$\begin{aligned}
 \int_1^2 x^3 dx &= \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x = \lim_{n \rightarrow \infty} \sum_{i=1}^n \left(1 + \frac{i}{n}\right)^3 \left(\frac{1}{n}\right) = \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \left(\frac{n+i}{n}\right)^3 \\
 &= \lim_{n \rightarrow \infty} \frac{1}{n^4} \sum_{i=1}^n (n^3 + 3n^2 i + 3ni^2 + i^3) = \lim_{n \rightarrow \infty} \frac{1}{n^4} \left[\sum_{i=1}^n n^3 + \sum_{i=1}^n 3n^2 i + \sum_{i=1}^n 3ni^2 + \sum_{i=1}^n i^3 \right] \\
 &= \lim_{n \rightarrow \infty} \frac{1}{n^4} \left[n \cdot n^3 + 3n^2 \sum_{i=1}^n i + 3n \sum_{i=1}^n i^2 + \sum_{i=1}^n i^3 \right] \\
 &= \lim_{n \rightarrow \infty} \left[1 + \frac{3}{n^2} \cdot \frac{n(n+1)}{2} + \frac{3}{n^3} \cdot \frac{n(n+1)(2n+1)}{6} + \frac{1}{n^4} \cdot \frac{n^2(n+1)^2}{4} \right] \\
 &= \lim_{n \rightarrow \infty} \left[1 + \frac{3}{2} \cdot \frac{n+1}{n} + \frac{1}{2} \cdot \frac{n+1}{n} \cdot \frac{2n+1}{n} + \frac{1}{4} \cdot \frac{(n+1)^2}{n^2} \right] \\
 &= \lim_{n \rightarrow \infty} \left[1 + \frac{3}{2} \left(1 + \frac{1}{n}\right) + \frac{1}{2} \left(1 + \frac{1}{n}\right) \left(2 + \frac{1}{n}\right) + \frac{1}{4} \left(1 + \frac{1}{n}\right)^2 \right] = 1 + \frac{3}{2} + \frac{1}{2} \cdot 2 + \frac{1}{4} = 3.75
 \end{aligned}$$

26. (a) $\Delta x = (4-0)/8 = 0.5$ and $x_i^* = x_i = 0.5i$.

$$\begin{aligned}
 \int_0^4 (x^2 - 3x) dx &\approx \sum_{i=1}^8 f(x_i^*) \Delta x \\
 &= 0.5 \{ [0.5^2 - 3(0.5)] + [1.0^2 - 3(1.0)] + \cdots \\
 &\quad + [3.5^2 - 3(3.5)] + [4.0^2 - 3(4.0)] \} \\
 &= \frac{1}{2} \left(-\frac{5}{4} - 2 - \frac{9}{4} - 2 - \frac{5}{4} + 0 + \frac{7}{4} + 4 \right) = -1.5
 \end{aligned}$$

(b)

$$\begin{aligned}
 \text{(c)} \quad \int_0^4 (x^2 - 3x) dx &= \lim_{n \rightarrow \infty} \sum_{i=1}^n \left[\left(\frac{4i}{n} \right)^2 - 3 \left(\frac{4i}{n} \right) \right] \left(\frac{4}{n} \right) \\
 &= \lim_{n \rightarrow \infty} \frac{4}{n} \left[\frac{16}{n^2} \sum_{i=1}^n i^2 - \frac{12}{n} \sum_{i=1}^n i \right] \\
 &= \lim_{n \rightarrow \infty} \left[\frac{64}{n^3} \cdot \frac{n(n+1)(2n+1)}{6} - \frac{48}{n^2} \cdot \frac{n(n+1)}{2} \right] \\
 &= \lim_{n \rightarrow \infty} \left[\frac{32}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) - 24 \left(1 + \frac{1}{n} \right) \right] \\
 &= \frac{32}{3} \cdot 2 - 24 = -\frac{8}{3}
 \end{aligned}$$

- (d) $\int_0^4 (x^2 - 3x) dx = A_1 - A_2$,
where A_1 is the area marked + and
 A_2 is the area marked -.

$$\begin{aligned}
 27. \quad \int_a^b x dx &= \lim_{n \rightarrow \infty} \frac{b-a}{n} \sum_{i=1}^n \left[a + \frac{b-a}{n} i \right] = \lim_{n \rightarrow \infty} \left[\frac{a(b-a)}{n} \sum_{i=1}^n 1 + \frac{(b-a)^2}{n^2} \sum_{i=1}^n i \right] \\
 &= \lim_{n \rightarrow \infty} \left[\frac{a(b-a)}{n} n + \frac{(b-a)^2}{n^2} \cdot \frac{n(n+1)}{2} \right] = a(b-a) + \lim_{n \rightarrow \infty} \frac{(b-a)^2}{2} \left(1 + \frac{1}{n} \right) \\
 &= a(b-a) + \frac{1}{2}(b-a)^2 = (b-a) \left(a + \frac{1}{2}b - \frac{1}{2}a \right) = (b-a) \frac{1}{2}(b+a) = \frac{1}{2}(b^2 - a^2)
 \end{aligned}$$

$$\begin{aligned}
 28. \int_a^b x^2 dx &= \lim_{n \rightarrow \infty} \frac{b-a}{n} \sum_{i=1}^n \left[a + \frac{b-a}{n} i \right]^2 = \lim_{n \rightarrow \infty} \frac{b-a}{n} \sum_{i=1}^n \left[a^2 + 2a \frac{b-a}{n} i + \frac{(b-a)^2}{n^2} i^2 \right] \\
 &= \lim_{n \rightarrow \infty} \left[\frac{(b-a)^3}{n^3} \sum_{i=1}^n i^2 + \frac{2a(b-a)^2}{n^2} \sum_{i=1}^n i + \frac{a^2(b-a)}{n} \sum_{i=1}^n 1 \right] \\
 &= \lim_{n \rightarrow \infty} \left[\frac{(b-a)^3}{n^3} \frac{n(n+1)(2n+1)}{6} + \frac{2a(b-a)^2}{n^2} \frac{n(n+1)}{2} + \frac{a^2(b-a)}{n} n \right] \\
 &= \lim_{n \rightarrow \infty} \left[\frac{(b-a)^3}{6} \cdot 1 \cdot \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) + a(b-a)^2 \cdot 1 \cdot \left(1 + \frac{1}{n} \right) + a^2(b-a) \right] \\
 &= \frac{(b-a)^3}{3} + a(b-a)^2 + a^2(b-a) = \frac{b^3 - 3ab^2 + 3a^2b - a^3}{3} + ab^2 - 2a^2b + a^3 + a^2b - a^3 \\
 &= \frac{b^3}{3} - \frac{a^3}{3} - ab^2 + a^2b + ab^2 - a^2b = \frac{b^3 - a^3}{3}
 \end{aligned}$$

29. $f(x) = \frac{x}{1+x^5}$, $a = 2$, $b = 6$, and $\Delta x = \frac{6-2}{n} = \frac{4}{n}$. Using Equation 3, we get $x_i^* = x_i = 2 + i \Delta x = 2 + \frac{4i}{n}$,

$$\text{so } \int_2^6 \frac{x}{1+x^5} dx = \lim_{n \rightarrow \infty} R_n = \lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{2 + \frac{4i}{n}}{1 + \left(2 + \frac{4i}{n} \right)^5} \cdot \frac{4}{n}.$$

30. $f(x) = x^2 \sin x$, $[a, b] = [0, 2\pi]$, $\Delta x = \frac{2\pi - 0}{n} = \frac{2\pi}{n}$, and $x_i = a + i \Delta x = \frac{2\pi i}{n}$, so

$$\int_0^{2\pi} x^2 \sin x dx = \lim_{n \rightarrow \infty} R_n = \lim_{n \rightarrow \infty} \sum_{i=1}^n \left[\left(\frac{2\pi i}{n} \right)^2 \sin \left(\frac{2\pi i}{n} \right) \right] \cdot \frac{2\pi}{n}.$$

31. $\Delta x = (\pi - 0)/n = \pi/n$ and $x_i^* = x_i = \pi i/n$.

$$\int_0^\pi \sin 5x dx = \lim_{n \rightarrow \infty} \sum_{i=1}^n (\sin 5x_i) \left(\frac{\pi}{n} \right) = \lim_{n \rightarrow \infty} \sum_{i=1}^n \left(\sin \frac{5\pi i}{n} \right) \frac{\pi}{n} \stackrel{\text{CAS}}{=} \pi \lim_{n \rightarrow \infty} \frac{1}{n} \cot \left(\frac{5\pi}{2n} \right) \stackrel{\text{CAS}}{=} \pi \left(\frac{2}{5\pi} \right) = \frac{2}{5}$$

32. $\Delta x = (10 - 2)/n = 8/n$ and $x_i^* = x_i = 2 + 8i/n$.

$$\begin{aligned}
 \int_2^{10} x^6 dx &= \lim_{n \rightarrow \infty} \sum_{i=1}^n \left(2 + \frac{8i}{n} \right)^6 \left(\frac{8}{n} \right) = 8 \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \left(2 + \frac{8i}{n} \right)^6 \\
 &\stackrel{\text{CAS}}{=} 8 \lim_{n \rightarrow \infty} \frac{1}{n} \cdot \frac{64(58,593n^6 + 164,052n^5 + 131,208n^4 - 27,776n^2 + 2048)}{21n^5} \\
 &\stackrel{\text{CAS}}{=} 8 \left(\frac{1,249,984}{7} \right) = \frac{9,999,872}{7} \approx 1,428,553.1
 \end{aligned}$$

33. (a) Think of $\int_0^2 f(x) dx$ as the area of a trapezoid with bases 1 and 3 and height 2. The area of a trapezoid is

$$A = \frac{1}{2}(b + B)h, \text{ so } \int_0^2 f(x) dx = \frac{1}{2}(1 + 3)2 = 4.$$

$$\begin{aligned}
 \text{(b) } \int_0^5 f(x) dx &= \int_0^2 f(x) dx + \int_2^3 f(x) dx + \int_3^5 f(x) dx \\
 &\quad \text{trapezoid} \quad \text{rectangle} \quad \text{triangle} \\
 &= \frac{1}{2}(1 + 3)2 + 3 \cdot 1 + \frac{1}{2} \cdot 2 \cdot 3 = 4 + 3 + 3 = 10
 \end{aligned}$$

(c) $\int_5^7 f(x) dx$ is the negative of the area of the triangle with base 2 and height 3. $\int_5^7 f(x) dx = -\frac{1}{2} \cdot 2 \cdot 3 = -3.$

- (d) $\int_7^9 f(x) dx$ is the negative of the area of a trapezoid with bases 3 and 2 and height 2, so it equals $-\frac{1}{2}(B+b)h = -\frac{1}{2}(3+2)2 = -5$. Thus,
- $$\int_0^9 f(x) dx = \int_0^5 f(x) dx + \int_5^7 f(x) dx + \int_7^9 f(x) dx = 10 + (-3) + (-5) = 2.$$

34. (a) $\int_0^2 g(x) dx = \frac{1}{2} \cdot 4 \cdot 2 = 4$ (area of a triangle)
 (b) $\int_2^6 g(x) dx = -\frac{1}{2}\pi(2)^2 = -2\pi$ (negative of the area of a semicircle)
 (c) $\int_6^7 g(x) dx = \frac{1}{2} \cdot 1 \cdot 1 = \frac{1}{2}$ (area of a triangle)
 $\int_0^7 g(x) dx = \int_0^2 g(x) dx + \int_2^6 g(x) dx + \int_6^7 g(x) dx = 4 - 2\pi + \frac{1}{2} = 4.5 - 2\pi$

35. $\int_0^3 (\frac{1}{2}x - 1) dx$ can be interpreted as the area of the triangle above the x -axis minus the area of the triangle below the x -axis; that is,
- $$\frac{1}{2}(1)(\frac{1}{2}) - \frac{1}{2}(2)(1) = \frac{1}{4} - 1 = -\frac{3}{4}.$$

36. $\int_{-2}^2 \sqrt{4-x^2} dx$ can be interpreted as the area under the graph of $f(x) = \sqrt{4-x^2}$ between $x = -2$ and $x = 2$. This is equal to half the area of the circle with radius 2, so $\int_{-2}^2 \sqrt{4-x^2} dx = \frac{1}{2}\pi \cdot 2^2 = 2\pi$.

37. $\int_{-3}^0 (1 + \sqrt{9-x^2}) dx$ can be interpreted as the area under the graph of $f(x) = 1 + \sqrt{9-x^2}$ between $x = -3$ and $x = 0$. This is equal to one-quarter the area of the circle with radius 3, plus the area of the rectangle, so
- $$\int_{-3}^0 (1 + \sqrt{9-x^2}) dx = \frac{1}{4}\pi \cdot 3^2 + 1 \cdot 3 = 3 + \frac{9}{4}\pi.$$

38. $\int_{-1}^3 (3-2x) dx$ can be interpreted as the area of the triangle above the x -axis minus the area of the triangle below the x -axis; that is,
- $$\frac{1}{2}(\frac{5}{2})(5) - \frac{1}{2}(\frac{3}{2})(3) = \frac{25}{4} - \frac{9}{4} = 4.$$

39. $\int_{-1}^2 |x| dx$ can be interpreted as the sum of the areas of the two shaded triangles; that is, $\frac{1}{2}(1)(1) + \frac{1}{2}(2)(2) = \frac{1}{2} + \frac{4}{2} = \frac{5}{2}$.

40. $\int_0^{10} |x - 5| dx$ can be interpreted as the sum of the areas of the two shaded triangles; that is, $2(\frac{1}{2})(5)(5) = 25$.

41. $\int_9^4 \sqrt{t} dt = -\int_4^9 \sqrt{t} dt$ [because we reversed the limits of integration]
 $= -\int_4^9 \sqrt{x} dx$ [we can use any letter without changing the value of the integral]
 $= -\frac{38}{3}$
42. $\int_1^1 x^2 \cos x dx = 0$ since the limits of integration are equal.
43. $\int_0^1 (5 - 6x^2) dx = \int_0^1 5 dx - 6 \int_0^1 x^2 dx = 5(1 - 0) - 6(\frac{1}{3}) = 5 - 2 = 3$
44. $\int_2^5 (1 + 3x^4) dx = \int_2^5 1 dx + \int_2^5 3x^4 dx = 1(5 - 2) + 3 \int_2^5 x^4 dx = 1(3) + 3(618.6) = 1858.8$
45. $\int_1^4 (2x^2 - 3x + 1) dx = 2 \int_1^4 x^2 dx - 3 \int_1^4 x dx + \int_1^4 1 dx$
 $= 2 \cdot \frac{1}{3}(4^3 - 1^3) - 3 \cdot \frac{1}{2}(4^2 - 1^2) + 1(4 - 1) = \frac{45}{2} = 22.5$
46. $\int_0^{\pi/2} (2 \cos x - 5x) dx = \int_0^{\pi/2} 2 \cos x dx - \int_0^{\pi/2} 5x dx = 2 \int_0^{\pi/2} \cos x dx - 5 \int_0^{\pi/2} x dx$
 $= 2(1) - 5 \frac{(\pi/2)^2 - 0^2}{2} = 2 - \frac{5\pi^2}{8}$
47. $\int_{-2}^2 f(x) dx + \int_2^5 f(x) dx - \int_{-2}^{-1} f(x) dx = \int_{-2}^5 f(x) dx + \int_{-1}^{-2} f(x) dx$ [by Property 5 and reversing limits]
 $= \int_{-1}^5 f(x) dx$ [Property 5]
48. $\int_1^4 f(x) dx = \int_1^5 f(x) dx - \int_4^5 f(x) dx = 12 - 3.6 = 8.4$
49. $\int_0^9 [2f(x) + 3g(x)] dx = 2 \int_0^9 f(x) dx + 3 \int_0^9 g(x) dx = 2(37) + 3(16) = 122$
50. If $f(x) = \begin{cases} 3 & \text{for } x < 3 \\ x & \text{for } x \geq 3 \end{cases}$, then $\int_0^5 f(x) dx$ can be interpreted as the area of the shaded region, which consists of a 5-by-3 rectangle surmounted by an isosceles right triangle whose legs have length 2. Thus,
 $\int_0^5 f(x) dx = 5(3) + \frac{1}{2}(2)(2) = 17$.
51. $0 \leq \sin x < 1$ on $[0, \frac{\pi}{4}]$, so $\sin^3 x \leq \sin^2 x$ on $[0, \frac{\pi}{4}]$. Hence, $\int_0^{\pi/4} \sin^3 x dx \leq \int_0^{\pi/4} \sin^2 x dx$ (Property 7).
52. $5 - x \geq 3 \geq x + 1$ on $[1, 2]$, so $\sqrt{5 - x} \geq \sqrt{x + 1}$ and $\int_1^2 \sqrt{5 - x} dx \geq \int_1^2 \sqrt{x + 1} dx$.
53. If $-1 \leq x \leq 1$, then $0 \leq x^2 \leq 1$ and $1 \leq 1 + x^2 \leq 2$, so $1 \leq \sqrt{1 + x^2} \leq \sqrt{2}$ and
 $1[1 - (-1)] \leq \int_{-1}^1 \sqrt{1 + x^2} dx \leq \sqrt{2}[1 - (-1)]$ [Property 8]; that is, $2 \leq \int_{-1}^1 \sqrt{1 + x^2} dx \leq 2\sqrt{2}$.
54. $\frac{1}{2} \leq \sin x \leq 1$ for $\frac{\pi}{6} \leq x \leq \frac{\pi}{2}$, so $\frac{1}{2}(\frac{\pi}{2} - \frac{\pi}{6}) \leq \int_{\pi/6}^{\pi/2} \sin x dx \leq 1(\frac{\pi}{2} - \frac{\pi}{6})$ [Property 8]; that is,
 $\frac{\pi}{6} \leq \int_{\pi/6}^{\pi/2} \sin x dx \leq \frac{\pi}{3}$.
55. If $1 \leq x \leq 2$, then $\frac{1}{2} \leq \frac{1}{x} \leq 1$, so $\frac{1}{2}(2 - 1) \leq \int_1^2 \frac{1}{x} dx \leq 1(2 - 1)$ or $\frac{1}{2} \leq \int_1^2 \frac{1}{x} dx \leq 1$.

56. If $0 \leq x \leq 2$, then $0 \leq x^3 \leq 8$, so $1 \leq x^3 + 1 \leq 9$ and $1 \leq \sqrt{x^3 + 1} \leq 3$. Thus,
 $1(2 - 0) \leq \int_0^2 \sqrt{x^3 + 1} dx \leq 3(2 - 0)$ that is, $2 \leq \int_0^2 \sqrt{x^3 + 1} dx \leq 6$.
57. If $\frac{\pi}{4} \leq x \leq \frac{\pi}{3}$, then $1 \leq \tan x \leq \sqrt{3}$, so $1(\frac{\pi}{3} - \frac{\pi}{4}) \leq \int_{\pi/4}^{\pi/3} \tan x dx \leq \sqrt{3}(\frac{\pi}{3} - \frac{\pi}{4})$ or
 $\frac{\pi}{12} \leq \int_{\pi/4}^{\pi/3} \tan x dx \leq \frac{\pi}{12}\sqrt{3}$.
58. Let $f(x) = x^3 - 3x + 3$ for $0 \leq x \leq 2$. Then $f'(x) = 3x^2 - 3 = 3(x+1)(x-1)$, so f is decreasing on $(0, 1)$ and increasing on $(1, 2)$. f has the absolute minimum value $f(1) = 1$. Since $f(0) = 3$ and $f(2) = 5$, the absolute maximum value of f is $f(2) = 5$. Thus, $1 \leq x^3 - 3x + 3 \leq 5$ for x in $[0, 2]$. It follows from Property 8 that
 $1 \cdot (2 - 0) \leq \int_0^2 (x^3 - 3x + 3) dx \leq 5 \cdot (2 - 0)$; that is, $2 \leq \int_0^2 (x^3 - 3x + 3) dx \leq 10$.
59. For $-1 \leq x \leq 1$, $0 \leq x^4 \leq 1$ and $1 \leq \sqrt{1+x^4} \leq \sqrt{2}$, so $1[1 - (-1)] \leq \int_{-1}^1 \sqrt{1+x^4} dx \leq \sqrt{2}[1 - (-1)]$ or
 $2 \leq \int_{-1}^1 \sqrt{1+x^4} dx \leq 2\sqrt{2}$.
60. If $\frac{1}{4}\pi \leq x \leq \frac{3}{4}\pi$, then $\frac{\sqrt{2}}{2} \leq \sin x \leq 1$ and $\frac{1}{2} \leq \sin^2 x \leq 1$, so $\frac{1}{2}(\frac{3}{4}\pi - \frac{1}{4}\pi) \leq \int_{\pi/4}^{3\pi/4} \sin^2 x dx \leq 1(\frac{3}{4}\pi - \frac{1}{4}\pi)$;
that is, $\frac{1}{4}\pi \leq \int_{\pi/4}^{3\pi/4} \sin^2 x dx \leq \frac{1}{2}\pi$.
61. $\sqrt{x^4 + 1} \geq \sqrt{x^4} = x^2$, so $\int_1^3 \sqrt{x^4 + 1} dx \geq \int_1^3 x^2 dx = \frac{1}{3}(3^3 - 1^3) = \frac{26}{3}$.
62. $0 \leq \sin x \leq 1$ for $0 \leq x \leq \frac{\pi}{2}$, so $x \sin x \leq x \Rightarrow \int_0^{\pi/2} x \sin x dx \leq \int_0^{\pi/2} x dx = \frac{1}{2}[(\frac{\pi}{2})^2 - 0^2] = \frac{\pi^2}{8}$.
63. Using a regular partition and right endpoints as in the proof of Property 2, we calculate
 $\int_a^b cf(x) dx = \lim_{n \rightarrow \infty} \sum_{i=1}^n cf(x_i) \Delta x_i = \lim_{n \rightarrow \infty} c \sum_{i=1}^n f(x_i) \Delta x_i = c \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x_i = c \int_a^b f(x) dx$.
64. As in the proof of Property 2, we write $\int_a^b f(x) dx = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x$. Now $f(x_i) \geq 0$ and $\Delta x \geq 0$, so
 $f(x_i) \Delta x \geq 0$ and therefore $\sum_{i=1}^n f(x_i) \Delta x \geq 0$. But the limit of nonnegative quantities is nonnegative by
Theorem 2.3.2, so $\int_a^b f(x) dx \geq 0$.
65. Since $-|f(x)| \leq f(x) \leq |f(x)|$, it follows from Property 7 that
 $-\int_a^b |f(x)| dx \leq \int_a^b f(x) dx \leq \int_a^b |f(x)| dx \Rightarrow \left| \int_a^b f(x) dx \right| \leq \int_a^b |f(x)| dx$
- Note that the definite integral is a real number, and so the following property applies: $-a \leq b \leq a \Rightarrow |b| \leq a$
for all real numbers b and nonnegative numbers a .
66. $\left| \int_0^{2\pi} f(x) \sin 2x dx \right| \leq \int_0^{2\pi} |f(x) \sin 2x| dx$ [by Exercise 65] $= \int_0^{2\pi} |f(x)| |\sin 2x| dx \leq \int_0^{2\pi} |f(x)| dx$ by
Property 7, since $|\sin 2x| \leq 1 \Rightarrow |f(x)| |\sin 2x| \leq |f(x)|$.
67. $\lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{i^4}{n^5} = \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \left(\frac{i}{n}\right)^4 = \int_0^1 x^4 dx$
68. $\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \frac{1}{1 + (i/n)^2} = \int_0^1 \frac{dx}{1 + x^2}$

69. Choose $x_i = 1 + \frac{i}{n}$ and $x_i^* = \sqrt{x_{i-1}x_i} = \sqrt{\left(1 + \frac{i-1}{n}\right)\left(1 + \frac{i}{n}\right)}$. Then

$$\begin{aligned}
 \int_1^2 x^{-2} dx &= \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \frac{1}{\left(1 + \frac{i-1}{n}\right)\left(1 + \frac{i}{n}\right)} \\
 &= \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \frac{1}{(n+i-1)(n+i)} \\
 &= \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \left(\frac{1}{n+i-1} - \frac{1}{n+i} \right) \quad [\text{by the hint}] \\
 &= \lim_{n \rightarrow \infty} \frac{1}{n} \left(\sum_{i=1}^n \frac{1}{n+i-1} - \sum_{i=1}^n \frac{1}{n+i} \right) \\
 &= \lim_{n \rightarrow \infty} \frac{1}{n} \left(\left[\frac{1}{n} + \frac{1}{n+1} + \cdots + \frac{1}{2n-1} \right] - \left[\frac{1}{n+1} + \cdots + \frac{1}{2n-1} + \frac{1}{2n} \right] \right) \\
 &= \lim_{n \rightarrow \infty} \frac{1}{n} \left(\frac{1}{n} - \frac{1}{2n} \right) = \lim_{n \rightarrow \infty} \left(1 - \frac{1}{2} \right) = \frac{1}{2}
 \end{aligned}$$

DISCOVERY PROJECT Area Functions

1. (a)

$$\begin{aligned}
 \text{Area of trapezoid} &= \frac{1}{2}(b_1 + b_2)h \\
 &= \frac{1}{2}(3 + 7)2 \\
 &= 10 \text{ square units}
 \end{aligned}$$

Or:

$$\begin{aligned}
 \text{Area of rectangle} + \text{area of triangle} \\
 &= b_r h_r + \frac{1}{2} b_t h_t \\
 &= (2)(3) + \frac{1}{2}(2)(4) = 10 \text{ square units}
 \end{aligned}$$

(c) $A'(x) = 2x + 1$. This is the y -coordinate of the point $(x, 2x + 1)$ on the given line.

(b)

As in part (a),

$$\begin{aligned}
 A(x) &= \frac{1}{2}[3 + (2x + 1)](x - 1) \\
 &= \frac{1}{2}(2x + 4)(x - 1) \\
 &= (x + 2)(x - 1) \\
 &= x^2 + x - 2 \text{ square units}
 \end{aligned}$$

2. (a)

$$\begin{aligned} \text{(b) } A(x) &= \int_{-1}^x (1+t^2) dt = \int_{-1}^x 1 dt + \int_{-1}^x t^2 dt \quad [\text{Property 2}] \\ &= 1[x - (-1)] + \frac{x^3 - (-1)^3}{3} \quad \left[\begin{array}{l} \text{Property 1 and} \\ \text{Exercise 5.2.28} \end{array} \right] \\ &= x + 1 + \frac{1}{3}x^3 + \frac{1}{3} \\ &= \frac{1}{3}x^3 + x + \frac{4}{3} \end{aligned}$$

(c) $A'(x) = x^2 + 1$. This is the y -coordinate of the point $(x, 1 + x^2)$ on the given curve.

(d)

$A(x+h) - A(x)$ is the area under the curve $y = 1 + t^2$ from $t = x$ to $t = x+h$.

(e)

An approximating rectangle is shown in the figure.

It has height $1 + x^2$, width h , and area $h(1 + x^2)$, so

$$A(x+h) - A(x) \approx h(1+x^2) \Rightarrow$$

$$\frac{A(x+h) - A(x)}{h} \approx 1 + x^2.$$

(f) Part (e) says that the average rate of change of A is approximately $1 + x^2$. As h approaches 0, the quotient approaches the instantaneous rate of change—namely, $A'(x)$. So the result of part (c), $A'(x) = x^2 + 1$, is geometrically plausible.

3. (a) $f(x) = \cos(x^2)$

(b) $g(x)$ starts to decrease at that value of x where $\cos(t^2)$ changes from positive to negative; that is, at about $x = 1.25$.

- (c) $g(x) = \int_0^x \cos(t^2) dt$. Using an integration command, we find that $g(0) = 0$, $g(0.2) \approx 0.200$, $g(0.4) \approx 0.399$, $g(0.6) \approx 0.592$, $g(0.8) \approx 0.768$, $g(1.0) \approx 0.905$, $g(1.2) \approx 0.974$, $g(1.4) \approx 0.950$, $g(1.6) \approx 0.826$, $g(1.8) \approx 0.635$, and $g(2.0) \approx 0.461$.

- (d) We sketch the graph of g' using the method of Example 1 in Section 3.2. The graphs of $g'(x)$ and $f(x)$ look alike, so we guess that $g'(x) = f(x)$.

4. In Problems 1 and 2, we showed that if $g(x) = \int_a^x f(t) dt$, then $g'(x) = f(x)$, for the functions $f(t) = 2t + 1$ and $f(t) = 1 + t^2$. In Problem 3 we guessed that the same is true for $f(t) = \cos(t^2)$, based on visual evidence. So we conjecture that $g'(x) = f(x)$ for any continuous function f . This turns out to be true and is proved in Section 5.3 (the Fundamental Theorem of Calculus).

5.3 The Fundamental Theorem of Calculus

1. The precise version of this statement is given by the Fundamental Theorem of Calculus. See the statement of this theorem and the paragraph that follows it at the end of Section 5.3.

2. (a) $g(x) = \int_0^x f(t) dt$, so $g(0) = \int_0^0 f(t) dt = 0$.

$$g(1) = \int_0^1 f(t) dt = \frac{1}{2} \cdot 1 \cdot 1 \text{ [area of triangle]} = \frac{1}{2}.$$

$$g(2) = \int_0^2 f(t) dt = \int_0^1 f(t) dt + \int_1^2 f(t) dt \text{ [below the } x\text{-axis]} \\ = \frac{1}{2} - \frac{1}{2} \cdot 1 \cdot 1 = 0.$$

$$g(3) = g(2) + \int_2^3 f(t) dt = 0 - \frac{1}{2} \cdot 1 \cdot 1 = -\frac{1}{2}.$$

$$g(4) = g(3) + \int_3^4 f(t) dt = -\frac{1}{2} + \frac{1}{2} \cdot 1 \cdot 1 = 0.$$

$$g(5) = g(4) + \int_4^5 f(t) dt = 0 + 1.5 = 1.5.$$

$$g(6) = g(5) + \int_5^6 f(t) dt = 1.5 + 2.5 = 4.$$

- (b) $g(7) = g(6) + \int_6^7 f(t) dt \approx 4 + 2.2 \text{ [estimate from the graph]} = 6.2$.

- (c) The answers from part (a) and part (b) indicate that g has a minimum at $x = 3$ and a maximum at $x = 7$. This makes sense from the graph of f since we are subtracting area on $1 < x < 3$ and adding area on $3 < x < 7$.

(d)

3. (a) $g(x) = \int_0^x f(t) dt$.

$$g(0) = \int_0^0 f(t) dt = 0$$

$$g(1) = \int_0^1 f(t) dt = 1 \cdot 2 = 2 \text{ [rectangle]},$$

$$g(2) = \int_0^2 f(t) dt = \int_0^1 f(t) dt + \int_1^2 f(t) dt = g(1) + \int_1^2 f(t) dt \\ = 2 + 1 \cdot 2 + \frac{1}{2} \cdot 1 \cdot 2 = 5 \text{ [rectangle plus triangle]},$$

$$g(3) = \int_0^3 f(t) dt = g(2) + \int_2^3 f(t) dt = 5 + \frac{1}{2} \cdot 1 \cdot 4 = 7,$$

$$g(6) = g(3) + \int_3^6 f(t) dt \text{ [the integral is negative since } f \text{ lies under the } x\text{-axis]} \\ = 7 + \left[-\left(\frac{1}{2} \cdot 2 \cdot 2 + 1 \cdot 2\right) \right] = 7 - 4 = 3$$

 (b) g is increasing on $(0, 3)$ because as x increases from 0 to 3, we keep adding more area.

 (c) g has a maximum value when we start subtracting area; that is, at $x = 3$.

4. (a) $g(-3) = \int_{-3}^{-3} f(t) dt = 0$, $g(3) = \int_{-3}^3 f(t) dt = \int_{-3}^0 f(t) dt + \int_0^3 f(t) dt = 0$ by symmetry, since the area above the x -axis is the same as the area below the axis.

(b) From the graph, it appears that to the nearest $\frac{1}{2}$, $g(-2) = \int_{-3}^{-2} f(t) dt \approx 1$, $g(-1) = \int_{-3}^{-1} f(t) dt \approx 3\frac{1}{2}$, and $g(0) = \int_{-3}^0 f(t) dt \approx 5\frac{1}{2}$.

 (c) g is increasing on $(-3, 0)$ because as x increases from -3 to 0, we keep adding more area.

 (d) g has a maximum value when we start subtracting area; that is, at $x = 0$.

 (f) The graph of $g'(x)$ is the same as that of $f(x)$, as indicated by FTC1.

(d)

(e)

5.

(a) By FTC1 with $f(t) = t^2$ and $a = 1$, $g(x) = \int_1^x t^2 dt \Rightarrow$

$$g'(x) = f(x) = x^2.$$

(b) Using FTC2, $g(x) = \int_1^x t^2 dt = \left[\frac{1}{3}t^3 \right]_1^x = \frac{1}{3}x^3 - \frac{1}{3} \Rightarrow$

$$g'(x) = x^2.$$

6.

(a) By FTC1 with $f(t) = 1 + \sqrt{t}$ and $a = 0$,

$$g(x) = \int_0^x (1 + \sqrt{t}) dt \Rightarrow g'(x) = f(x) = 1 + \sqrt{x}.$$

(b) Using FTC2, $g(x) = \int_0^x (1 + \sqrt{t}) dt = \left[t + \frac{2}{3}t^{3/2} \right]_0^x = x + \frac{2}{3}x^{3/2}$

$$\Rightarrow g'(x) = 1 + x^{1/2} = 1 + \sqrt{x}.$$

7. $f(t) = \sqrt{1+2t}$ and $g(x) = \int_0^x \sqrt{1+2t} dt$, so by FTC1, $g'(x) = f(x) = \sqrt{1+2x}$.

8. $f(t) = (2+t^4)^5$ and $g(x) = \int_1^x (2+t^4)^5 dt$, so $g'(x) = f(x) = (2+x^4)^5$.

9. $f(t) = t^2 \sin t$ and $g(y) = \int_2^y t^2 \sin t dt$, so by FTC1, $g'(y) = f(y) = y^2 \sin y$.

10. $f(x) = \frac{1}{x+x^2}$ and $g(u) = \int_3^u \frac{1}{x+x^2} dx$, so $g'(u) = f(u) = \frac{1}{u+u^2}$.

$$11. F(x) = \int_x^2 \cos(t^2) dt = - \int_2^x \cos(t^2) dt \Rightarrow F'(x) = -\cos(x^2)$$

$$12. f(\theta) = \tan \theta \text{ and } F(x) = \int_x^{10} \tan \theta d\theta = - \int_{10}^x \tan \theta d\theta, \text{ so by FTC1, } F'(x) = -f(x) = -\tan x.$$

$$13. \text{ Let } u = \frac{1}{x}. \text{ Then } \frac{du}{dx} = -\frac{1}{x^2}. \text{ Also, } \frac{dh}{dx} = \frac{dh}{du} \frac{du}{dx}, \text{ so}$$

$$h'(x) = \frac{d}{dx} \int_2^{1/x} \sin^4 t dt = \frac{d}{du} \int_2^u \sin^4 t dt \cdot \frac{du}{dx} = \sin^4 u \frac{du}{dx} = \frac{-\sin^4(1/x)}{x^2}.$$

$$14. \text{ Let } u = x^2. \text{ Then } \frac{du}{dx} = 2x. \text{ Also, } \frac{dh}{dx} = \frac{dh}{du} \frac{du}{dx}, \text{ so}$$

$$h'(x) = \frac{d}{dx} \int_0^{x^2} \sqrt{1+r^3} dr = \frac{d}{du} \int_0^u \sqrt{1+r^3} dr \cdot \frac{du}{dx} = \sqrt{1+u^3}(2x) = 2x \sqrt{1+(x^2)^3} = 2x \sqrt{1+x^6}.$$

$$15. \text{ Let } u = \sqrt{x}. \text{ Then } \frac{du}{dx} = \frac{1}{2\sqrt{x}}. \text{ Also, } \frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx}, \text{ so}$$

$$y' = \frac{d}{dx} \int_3^{\sqrt{x}} \frac{\cos t}{t} dt = \frac{d}{du} \int_3^u \frac{\cos t}{t} dt \cdot \frac{du}{dx} = \frac{\cos u}{u} \cdot \frac{1}{2\sqrt{x}} = \frac{\cos \sqrt{x}}{\sqrt{x}} \cdot \frac{1}{2\sqrt{x}} = \frac{\cos \sqrt{x}}{2x}.$$

$$16. \text{ Let } u = \cos x. \text{ Then } \frac{du}{dx} = -\sin x. \text{ Also, } \frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx}, \text{ so}$$

$$\begin{aligned} y' &= \frac{d}{dx} \int_1^{\cos x} (t + \sin t) dt = \frac{d}{du} \int_1^u (t + \sin t) dt \cdot \frac{du}{dx} \\ &= (u + \sin u) \cdot (-\sin x) = -\sin x [\cos x + \sin(\cos x)] \end{aligned}$$

$$17. \text{ Let } w = 1 - 3x. \text{ Then } \frac{dw}{dx} = -3. \text{ Also, } \frac{dy}{dx} = \frac{dy}{dw} \frac{dw}{dx}, \text{ so}$$

$$\begin{aligned} y' &= \frac{d}{dx} \int_{1-3x}^1 \frac{u^3}{1+u^2} du = \frac{d}{dw} \int_w^1 \frac{u^3}{1+u^2} du \cdot \frac{dw}{dx} \\ &= -\frac{d}{dw} \int_1^w \frac{u^3}{1+u^2} du \cdot \frac{dw}{dx} = -\frac{w^3}{1+w^2}(-3) = \frac{3(1-3x)^3}{1+(1-3x)^2} \end{aligned}$$

$$18. \text{ Let } u = \frac{1}{x^2}. \text{ Then } \frac{du}{dx} = -\frac{2}{x^3}. \text{ Also, } \frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx}, \text{ so}$$

$$y' = \frac{d}{dx} \int_{1/x^2}^0 \sin^3 t dt = \frac{d}{du} \int_u^0 \sin^3 t dt \cdot \frac{du}{dx} = -\frac{d}{du} \int_0^u \sin^3 t dt \cdot \frac{du}{dx} = -\sin^3 u \left(-\frac{2}{x^3}\right) = \frac{2 \sin^3(1/x^2)}{x^3}.$$

$$19. \int_{-1}^3 x^5 dx = \left[\frac{x^6}{6} \right]_{-1}^3 = \frac{3^6}{6} - \frac{(-1)^6}{6} = \frac{729-1}{6} = \frac{364}{3}$$

$$20. \int_{-2}^5 6 dx = [6x]_{-2}^5 = 6[5 - (-2)] = 6(7) = 42$$

$$21. \int_2^8 (4x+3) dx = \left[\frac{4}{2}x^2 + 3x \right]_2^8 = (2 \cdot 8^2 + 3 \cdot 8) - (2 \cdot 2^2 + 3 \cdot 2) = 152 - 14 = 138$$

$$22. \int_0^4 (1+3y-y^2) dy = \left[y + \frac{3}{2}y^2 - \frac{1}{3}y^3 \right]_0^4 = \left(4 + \frac{3}{2} \cdot 16 - \frac{1}{3} \cdot 64 \right) - (0) = \frac{20}{3}$$

$$23. \int_0^1 x^{4/5} dx = \left[\frac{5}{9}x^{9/5} \right]_0^1 = \frac{5}{9} - 0 = \frac{5}{9}$$

$$24. \int_1^8 \sqrt[3]{x} dx = \int_1^8 x^{1/3} dx = \left[\frac{3}{4}x^{4/3} \right]_1^8 = \frac{3}{4}(8^{4/3} - 1^{4/3}) = \frac{3}{4}(2^4 - 1) = \frac{3}{4}(16 - 1) = \frac{3}{4}(15) = \frac{45}{4}$$

$$25. \int_1^2 \frac{3}{t^4} dt = 3 \int_1^2 t^{-4} dt = 3 \left[\frac{t^{-3}}{-3} \right]_1^2 = \frac{3}{-3} \left[\frac{1}{t^3} \right]_1^2 = -1 \left(\frac{1}{8} - 1 \right) = \frac{7}{8}$$

26. $\int_{-2}^3 x^{-5} dx$ does not exist because the function $f(x) = x^{-5}$ has an infinite discontinuity at $x = 0$; that is, f is discontinuous on the interval $[-2, 3]$.
27. $\int_{-5}^5 \frac{2}{x^3} dx$ does not exist because the function $f(x) = \frac{2}{x^3}$ has an infinite discontinuity at $x = 0$; that is, f is discontinuous on the interval $[-5, 5]$.
28. $\int_{\pi}^{2\pi} \cos \theta d\theta = [\sin \theta]_{\pi}^{2\pi} = \sin 2\pi - \sin \pi = 0 - 0 = 0$
29. $\int_0^2 x(2 + x^5) dx = \int_0^2 (2x + x^6) dx = [x^2 + \frac{1}{7}x^7]_0^2 = (4 + \frac{128}{7}) - (0 + 0) = \frac{156}{7}$
30. $\int_1^4 \frac{1}{\sqrt{x}} dx = \int_1^4 x^{-1/2} dx = \left[\frac{x^{1/2}}{1/2} \right]_1^4 = [2x^{1/2}]_1^4 = 2\sqrt{4} - 2\sqrt{1} = 4 - 2 = 2$
31. $\int_0^{\pi/4} \sec^2 t dt = [\tan t]_0^{\pi/4} = \tan \frac{\pi}{4} - \tan 0 = 1 - 0 = 1$
32. $\int_0^1 (3 + x\sqrt{x}) dx = \int_0^1 (3 + x^{3/2}) dx = [3x + \frac{2}{5}x^{5/2}]_0^1 = [(3 + \frac{2}{5}) - 0] = \frac{17}{5}$
33. $\int_{\pi}^{2\pi} \csc^2 \theta d\theta$ does not exist because the function $f(\theta) = \csc^2 \theta$ has infinite discontinuities at $\theta = \pi$ and $\theta = 2\pi$; that is, f is discontinuous on the interval $[\pi, 2\pi]$.
34. $\int_0^{\pi/6} \csc \theta \cot \theta d\theta$ does not exist because the function $f(\theta) = \csc \theta \cot \theta$ has an infinite discontinuity at $\theta = 0$; that is, f is discontinuous on the interval $[0, \frac{\pi}{6}]$.
35. $\int_0^2 f(x) dx = \int_0^1 x^4 dx + \int_1^2 x^5 dx = [\frac{1}{5}x^5]_0^1 + [\frac{1}{6}x^6]_1^2 = (\frac{1}{5} - 0) + (\frac{64}{6} - \frac{1}{6}) = 10.7$
36. $\int_{-\pi}^{\pi} f(x) dx = \int_{-\pi}^0 x dx + \int_0^{\pi} \sin x dx = [\frac{1}{2}x^2]_{-\pi}^0 - [\cos x]_0^{\pi} = (0 - \frac{\pi^2}{2}) - (\cos \pi - \cos 0)$
 $= -\frac{\pi^2}{2} - (-1 - 1) = 2 - \frac{\pi^2}{2}$
37. From the graph, it appears that the area is about 60. The actual area is
 $\int_0^{27} x^{1/3} dx = [\frac{3}{4}x^{4/3}]_0^{27} = \frac{3}{4} \cdot 81 - 0 = \frac{243}{4} = 60.75$. This is $\frac{3}{4}$ of the area of the viewing rectangle.

38. From the graph, it appears that the area is about $\frac{1}{3}$. The actual area is

$$\int_1^6 x^{-4} dx = \left[\frac{x^{-3}}{-3} \right]_1^6 = \left[\frac{-1}{3x^3} \right]_1^6 = -\frac{1}{3 \cdot 216} + \frac{1}{3} = \frac{215}{648} \approx 0.3318.$$

39. It appears that the area under the graph is about $\frac{2}{3}$ of the area of the viewing rectangle, or about $\frac{2}{3}\pi \approx 2.1$. The actual area is

$$\int_0^{\pi} \sin x dx = [-\cos x]_0^{\pi} = (-\cos \pi) - (-\cos 0) = -(-1) + 1 = 2.$$

40. Splitting up the region as shown, we estimate that the area under the graph

is $\frac{\pi}{3} + \frac{1}{4}(3 \cdot \frac{\pi}{3}) \approx 1.8$. The actual area is

$$\int_0^{\pi/3} \sec^2 x \, dx = [\tan x]_0^{\pi/3} = \sqrt{3} - 0 = \sqrt{3} \approx 1.73.$$

41. $\int_{-1}^2 x^3 \, dx = [\frac{1}{4}x^4]_{-1}^2 = 4 - \frac{1}{4} = \frac{15}{4} = 3.75$

42. $\int_{\pi/4}^{5\pi/2} \sin x \, dx = [-\cos x]_{\pi/4}^{5\pi/2} = 0 + \frac{\sqrt{2}}{2} = \frac{\sqrt{2}}{2}$

43. $g(x) = \int_{2x}^{3x} \frac{u^2 - 1}{u^2 + 1} \, du = \int_{2x}^0 \frac{u^2 - 1}{u^2 + 1} \, du + \int_0^{3x} \frac{u^2 - 1}{u^2 + 1} \, du = -\int_0^{2x} \frac{u^2 - 1}{u^2 + 1} \, du + \int_0^{3x} \frac{u^2 - 1}{u^2 + 1} \, du \Rightarrow$

$$g'(x) = -\frac{(2x)^2 - 1}{(2x)^2 + 1} \cdot \frac{d}{dx}(2x) + \frac{(3x)^2 - 1}{(3x)^2 + 1} \cdot \frac{d}{dx}(3x) = -2 \cdot \frac{4x^2 - 1}{4x^2 + 1} + 3 \cdot \frac{9x^2 - 1}{9x^2 + 1}$$

44. $g(x) = \int_{\tan x}^{x^2} \frac{1}{\sqrt{2+t^4}} \, dt = \int_{\tan x}^1 \frac{dt}{\sqrt{2+t^4}} + \int_1^{x^2} \frac{dt}{\sqrt{2+t^4}} = -\int_1^{\tan x} \frac{dt}{\sqrt{2+t^4}} + \int_1^{x^2} \frac{dt}{\sqrt{2+t^4}} \Rightarrow$

$$g'(x) = \frac{-1}{\sqrt{2+\tan^4 x}} \frac{d}{dx}(\tan x) + \frac{1}{\sqrt{2+x^8}} \frac{d}{dx}(x^2) = -\frac{\sec^2 x}{\sqrt{2+\tan^4 x}} + \frac{2x}{\sqrt{2+x^8}}$$

45. $y = \int_{\sqrt{x}}^{x^3} \sqrt{t} \sin t \, dt = \int_{\sqrt{x}}^1 \sqrt{t} \sin t \, dt + \int_1^{x^3} \sqrt{t} \sin t \, dt = -\int_1^{\sqrt{x}} \sqrt{t} \sin t \, dt + \int_1^{x^3} \sqrt{t} \sin t \, dt \Rightarrow$

$$y' = -\frac{1}{2\sqrt{x}} (\sin \sqrt{x}) \cdot \frac{d}{dx}(\sqrt{x}) + x^{3/2} \sin(x^3) \cdot \frac{d}{dx}(x^3) = -\frac{\sqrt{x} \sin \sqrt{x}}{2\sqrt{x}} + x^{3/2} \sin(x^3) (3x^2)$$

$$= 3x^{7/2} \sin(x^3) - \frac{\sin \sqrt{x}}{2\sqrt{x}}$$

46. $y = \int_{\cos x}^{5x} \cos(u^2) \, du = \int_0^{5x} \cos(u^2) \, du - \int_0^{\cos x} \cos(u^2) \, du \Rightarrow$

$$y' = \cos(25x^2) \cdot \frac{d}{dx}(5x) - \cos(\cos^2 x) \cdot \frac{d}{dx}(\cos x) = \cos(25x^2) \cdot 5 - \cos(\cos^2 x) \cdot (-\sin x)$$

$$= 5 \cos(25x^2) + \sin x \cos(\cos^2 x)$$

47. $F(x) = \int_1^x f(t) \, dt \Rightarrow F'(x) = f(x) = \int_1^{x^2} \frac{\sqrt{1+u^4}}{u} \, du \left[\text{since } f(t) = \int_1^{t^2} \frac{\sqrt{1+u^4}}{u} \, du \right] \Rightarrow$

$$F''(x) = f'(x) = \frac{\sqrt{1+(x^2)^4}}{x^2} \cdot \frac{d}{dx}(x^2) = \frac{\sqrt{1+x^8}}{x^2} \cdot 2x = \frac{2\sqrt{1+x^8}}{x}. \text{ So } F''(2) = \sqrt{1+2^8} = \sqrt{257}.$$

48. For the curve to be concave upward, we must have $y'' > 0$. $y = \int_0^x \frac{1}{1+t+t^2} \, dt \Rightarrow y' = \frac{1}{1+x+x^2} \Rightarrow$

$$y'' = \frac{-(1+2x)}{(1+x+x^2)^2}. \text{ For this expression to be positive, we must have } (1+2x) < 0, \text{ since } (1+x+x^2)^2 > 0 \text{ for}$$

all x . $(1+2x) < 0 \Leftrightarrow x < -\frac{1}{2}$. Thus, the curve is concave upward on $(-\infty, -\frac{1}{2})$.

49. (a) The Fresnel function $S(x) = \int_0^x \sin(\frac{\pi}{2}t^2) dt$ has local maximum values where $0 = S'(x) = \sin(\frac{\pi}{2}x^2)$ and S' changes from positive to negative. For $x > 0$, this happens when $\frac{\pi}{2}x^2 = (2n-1)\pi$ [odd multiples of π] $\Leftrightarrow x^2 = 2(2n-1) \Leftrightarrow x = \sqrt{4n-2}$, n any positive integer. For $x < 0$, S' changes from positive to negative where $\frac{\pi}{2}x^2 = 2n\pi$ [even multiples of π] $\Leftrightarrow x^2 = 4n \Leftrightarrow x = -2\sqrt{n}$. S' does not change sign at $x = 0$.
- (b) S is concave upward on those intervals where $S''(x) > 0$. Differentiating our expression for $S'(x)$, we get $S''(x) = \cos(\frac{\pi}{2}x^2)(2\frac{\pi}{2}x) = \pi x \cos(\frac{\pi}{2}x^2)$. For $x > 0$, $S''(x) > 0$ where $\cos(\frac{\pi}{2}x^2) > 0 \Leftrightarrow 0 < \frac{\pi}{2}x^2 < \frac{\pi}{2}$ or $(2n - \frac{1}{2})\pi < \frac{\pi}{2}x^2 < (2n + \frac{1}{2})\pi$, n any integer $\Leftrightarrow 0 < x < 1$ or $\sqrt{4n-1} < x < \sqrt{4n+1}$, n any positive integer. For $x < 0$, $S''(x) > 0$ where $\cos(\frac{\pi}{2}x^2) < 0 \Leftrightarrow (2n - \frac{3}{2})\pi < \frac{\pi}{2}x^2 < (2n - \frac{1}{2})\pi$, n any integer $\Leftrightarrow 4n-3 < x^2 < 4n-1 \Leftrightarrow \sqrt{4n-3} < |x| < \sqrt{4n-1} \Rightarrow \sqrt{4n-3} < -x < \sqrt{4n-1} \Rightarrow -\sqrt{4n-3} > x > -\sqrt{4n-1}$, so the intervals of upward concavity for $x < 0$ are $(-\sqrt{4n-1}, -\sqrt{4n-3})$, n any positive integer. To summarize: S is concave upward on the intervals $(0, 1)$, $(-\sqrt{3}, -1)$, $(\sqrt{3}, \sqrt{5})$, $(-\sqrt{7}, -\sqrt{5})$, $(\sqrt{7}, 3)$,
- (c) In Maple, we use `plot({int(sin(Pi*t^2/2), t=0..x), 0.2}, x=0..2);`. Note that Maple recognizes the Fresnel function, calling it `FresnelS(x)`. In Mathematica, we use `Plot[{Integrate[Sin[Pi*t^2/2], {t, 0, x}], 0.2}, {x, 0, 2}]`. In Derive, we load the utility file `FRESNEL` and plot `FRESNEL_SIN(x)`. From the graphs, we see that $\int_0^x \sin(\frac{\pi}{2}t^2) dt = 0.2$ at $x \approx 0.74$.

50. (a) In Maple, we should start by setting `si:=int(sin(t)/t, t=0..x);`. In Mathematica, the command is `si=Integrate[Sin[t]/t, {t, 0, x}]`. Note that both systems recognize this function; Maple calls it `Si(x)` and Mathematica calls it `SinIntegral[x]`. In Maple, the command to generate the graph is `plot(si, x=-4*Pi..4*Pi);`. In Mathematica, it is `Plot[si, {x, -4*Pi, 4*Pi}]`. In Derive, we load the utility file `EXP_INT` and plot `SI(x)`.

- (b) $Si(x)$ has local maximum values where $Si'(x)$ changes from positive to negative, passing through 0. From the Fundamental Theorem we know that $Si'(x) = \frac{d}{dx} \int_0^x \frac{\sin t}{t} dt = \frac{\sin x}{x}$, so we must have $\sin x = 0$ for a maximum, and for $x > 0$ we must have $x = (2n-1)\pi$, n any positive integer, for Si' to be changing from positive to negative at x . For $x < 0$, we must have $x = 2n\pi$, n any positive integer, for a maximum, since the denominator of $Si'(x)$ is negative for $x < 0$. Thus, the local maxima occur at $x = \pi, -2\pi, 3\pi, -4\pi, 5\pi, -6\pi, \dots$
- (c) To find the first inflection point, we solve $Si''(x) = \frac{\cos x}{x} - \frac{\sin x}{x^2} = 0$. We can see from the graph that the first inflection point lies somewhere between $x = 3$ and $x = 5$. Using a root finder gives the value $x \approx 4.4934$. To find the y -coordinate of the inflection point, we evaluate $Si(4.4934) \approx 1.6556$. So the coordinates of the first

inflection point to the right of the origin are about (4.4934, 1.6556). Alternatively, we could graph $S''(x)$ and estimate the first positive x -value at which it changes sign.

- (d) It seems from the graph that the function has horizontal asymptotes at $y \approx 1.5$, with $\lim_{x \rightarrow \pm\infty} \text{Si}(x) \approx \pm 1.5$ respectively. Using the limit command, we get $\lim_{x \rightarrow \infty} \text{Si}(x) = \frac{\pi}{2}$. Since $\text{Si}(x)$ is an odd function,

$\lim_{x \rightarrow -\infty} \text{Si}(x) = -\frac{\pi}{2}$. So $\text{Si}(x)$ has the horizontal asymptotes $y = \pm \frac{\pi}{2}$.

- (e) We use the `fsolve` command in Maple (or `FindRoot` in Mathematica) to find that the solution is $x \approx 1.1$. Or, as in Exercise 49(c), we graph $y = \text{Si}(x)$ and $y = 1$ on the same screen to see where they intersect.

51. (a) By FTC1, $g'(x) = f(x)$. So $g'(x) = f(x) = 0$ at $x = 1, 3, 5, 7$, and 9 . g has local maxima at $x = 1$ and 5 (since $f = g'$ changes from positive to negative there) and local minima at $x = 3$ and 7 . There is no local maximum or minimum at $x = 9$, since f is not defined for $x > 9$.

- (b) We can see from the graph that $\left| \int_0^1 f \, dt \right| < \left| \int_1^3 f \, dt \right| < \left| \int_3^5 f \, dt \right| < \left| \int_5^7 f \, dt \right| < \left| \int_7^9 f \, dt \right|$.

So $g(1) = \left| \int_0^1 f \, dt \right|$, $g(5) = \int_0^5 f \, dt = g(1) - \left| \int_1^3 f \, dt \right| + \left| \int_3^5 f \, dt \right|$, and

$g(9) = \int_0^9 f \, dt = g(5) - \left| \int_5^7 f \, dt \right| + \left| \int_7^9 f \, dt \right|$. Thus, $g(1) < g(5) < g(9)$, and so the absolute maximum of $g(x)$ occurs at $x = 9$.

- (c) g is concave downward on those intervals where $g'' < 0$. But

$g'(x) = f(x)$, so $g''(x) = f'(x)$, which is negative on

(approximately) $(\frac{1}{2}, 2)$, $(4, 6)$ and $(8, 9)$. So g is concave downward on these intervals.

52. (a) By FTC1, $g'(x) = f(x)$. So $g'(x) = f(x) = 0$ at $x = 2, 4, 6, 8$, and 10 . g has local maxima at $x = 2$ and 6 (since $f = g'$ changes from positive to negative there) and local minima at $x = 4$ and 8 . There is no local maximum or minimum at $x = 10$, since f is not defined for $x > 10$.

- (b) We can see from the graph that $\left| \int_0^2 f \, dt \right| > \left| \int_2^4 f \, dt \right| > \left| \int_4^6 f \, dt \right| > \left| \int_6^8 f \, dt \right| > \left| \int_8^{10} f \, dt \right|$.

So $g(2) = \left| \int_0^2 f \, dt \right|$, $g(6) = \int_0^6 f \, dt = g(2) - \left| \int_2^4 f \, dt \right| + \left| \int_4^6 f \, dt \right|$, and

$g(10) = \int_0^{10} f \, dt = g(6) - \left| \int_6^8 f \, dt \right| + \left| \int_8^{10} f \, dt \right|$. Thus, $g(2) > g(6) > g(10)$, and so the absolute maximum of $g(x)$ occurs at $x = 2$.

- (c) g is concave downward on those intervals where $g'' < 0$. But

$g'(x) = f(x)$, so $g''(x) = f'(x)$, which is negative on $(1, 3)$, $(5, 7)$

and $(9, 10)$. So g is concave downward on these intervals.

53. $\lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{i^3}{n^4} = \lim_{n \rightarrow \infty} \frac{1-0}{n} \sum_{i=1}^n \left(\frac{i}{n} \right)^3 = \int_0^1 x^3 \, dx = \left[\frac{x^4}{4} \right]_0^1 = \frac{1}{4}$

54. $\lim_{n \rightarrow \infty} \frac{1}{n} \left(\sqrt{\frac{1}{n}} + \sqrt{\frac{2}{n}} + \cdots + \sqrt{\frac{n}{n}} \right) = \lim_{n \rightarrow \infty} \frac{1-0}{n} \sum_{i=1}^n \sqrt{\frac{i}{n}} = \int_0^1 \sqrt{x} \, dx = \left[\frac{2x^{3/2}}{3} \right]_0^1 = \frac{2}{3} - 0 = \frac{2}{3}$

55. Suppose $h < 0$. Since f is continuous on $[x + h, x]$, the Extreme Value Theorem says that there are numbers u and v in $[x + h, x]$ such that $f(u) = m$ and $f(v) = M$, where m and M are the absolute minimum and maximum values of f on $[x + h, x]$. By Property 8 of integrals, $m(-h) \leq \int_{x+h}^x f(t) dt \leq M(-h)$; that is,

$$f(u)(-h) \leq -\int_{x+h}^x f(t) dt \leq f(v)(-h). \text{ Since } -h > 0, \text{ we can divide this inequality by } -h:$$

$$f(u) \leq \frac{1}{h} \int_x^{x+h} f(t) dt \leq f(v). \text{ By Equation 2, } \frac{g(x+h) - g(x)}{h} = \frac{1}{h} \int_x^{x+h} f(t) dt \text{ for } h \neq 0, \text{ and hence}$$

$$f(u) \leq \frac{g(x+h) - g(x)}{h} \leq f(v), \text{ which is Equation 3 in the case where } h < 0.$$

$$\begin{aligned} 56. \frac{d}{dx} \int_{g(x)}^{h(x)} f(t) dt &= \frac{d}{dx} \left[\int_{g(x)}^a f(t) dt + \int_a^{h(x)} f(t) dt \right] \quad (\text{where } a \text{ is in the domain of } f) \\ &= \frac{d}{dx} \left[-\int_a^{g(x)} f(t) dt \right] + \frac{d}{dx} \left[\int_a^{h(x)} f(t) dt \right] = -f(g(x)) g'(x) + f(h(x)) h'(x) \\ &= f(h(x)) h'(x) - f(g(x)) g'(x) \end{aligned}$$

57. (a) Let $f(x) = \sqrt{x} \Rightarrow f'(x) = 1/(2\sqrt{x}) > 0$ for $x > 0 \Rightarrow f$ is increasing on $(0, \infty)$. If $x \geq 0$, then $x^3 \geq 0$, so $1 + x^3 \geq 1$ and since f is increasing, this means that $f(1 + x^3) \geq f(1) \Rightarrow \sqrt{1 + x^3} \geq 1$ for $x \geq 0$. Next let $g(t) = t^2 - t \Rightarrow g'(t) = 2t - 1 \Rightarrow g'(t) > 0$ when $t \geq 1$. Thus, g is increasing on $(1, \infty)$. And since $g(1) = 0$, $g(t) \geq 0$ when $t \geq 1$. Now let $t = \sqrt{1 + x^3}$, where $x \geq 0$. $\sqrt{1 + x^3} \geq 1$ (from above) $\Rightarrow t \geq 1 \Rightarrow g(t) \geq 0 \Rightarrow (1 + x^3) - \sqrt{1 + x^3} \geq 0$ for $x \geq 0$. Therefore, $1 \leq \sqrt{1 + x^3} \leq 1 + x^3$ for $x \geq 0$.

$$\begin{aligned} \text{(b) From part (a) and Property 7: } \int_0^1 1 dx &\leq \int_0^1 \sqrt{1 + x^3} dx \leq \int_0^1 (1 + x^3) dx \Leftrightarrow \\ [x]_0^1 &\leq \int_0^1 \sqrt{1 + x^3} dx \leq [x + \frac{1}{4}x^4]_0^1 \Leftrightarrow 1 \leq \int_0^1 \sqrt{1 + x^3} dx \leq 1 + \frac{1}{4} = 1.25. \end{aligned}$$

58. (a) If $x < 0$, then $g(x) = \int_0^x f(t) dt = \int_0^x 0 dt = 0$.

$$\text{If } 0 \leq x \leq 1, \text{ then } g(x) = \int_0^x f(t) dt = \int_0^x t dt = \left[\frac{1}{2}t^2 \right]_0^x = \frac{1}{2}x^2.$$

If $1 < x \leq 2$, then

$$\begin{aligned} g(x) &= \int_0^x f(t) dt = \int_0^1 f(t) dt + \int_1^x f(t) dt \\ &= g(1) + \int_1^x (2 - t) dt = \frac{1}{2}(1)^2 + \left[2t - \frac{1}{2}t^2 \right]_1^x \\ &= \frac{1}{2} + (2x - \frac{1}{2}x^2) - (2 - \frac{1}{2}) = 2x - \frac{1}{2}x^2 - 1. \end{aligned}$$

$$\text{If } x > 2, \text{ then } g(x) = \int_0^x f(t) dt = g(2) + \int_2^x 0 dt = 1 + 0 = 1. \text{ So}$$

$$g(x) = \begin{cases} 0 & \text{if } x < 0 \\ \frac{1}{2}x^2 & \text{if } 0 \leq x \leq 1 \\ 2x - \frac{1}{2}x^2 - 1 & \text{if } 1 < x \leq 2 \\ 1 & \text{if } x > 2 \end{cases}$$

(b)

- (c) f is not differentiable at its corners at $x = 0, 1$, and 2 . f is differentiable on $(-\infty, 0)$, $(0, 1)$, $(1, 2)$ and $(2, \infty)$. g is differentiable on $(-\infty, \infty)$.

59. Using FTC1, we differentiate both sides of $6 + \int_a^x \frac{f(t)}{t^2} dt = 2\sqrt{x}$ to get $\frac{f(x)}{x^2} = 2 \frac{1}{2\sqrt{x}} \Rightarrow f(x) = x^{3/2}$.

To find a , we substitute $x = a$ in the original equation to obtain $6 + \int_a^a \frac{f(t)}{t^2} dt = 2\sqrt{a} \Rightarrow 6 + 0 = 2\sqrt{a} \Rightarrow 3 = \sqrt{a} \Rightarrow a = 9$.

60. By the Fundamental Theorem of Calculus, $\int_1^2 (h')'(u) du = h'(2) - h'(1) = 5 - 2 = 3$. The other information is unnecessary.

61. (a) Let $F(t) = \int_0^t f(s) ds$. Then, by FTC1, $F'(t) = f(t) = \text{rate of depreciation}$, so $F(t)$ represents the loss in value over the interval $[0, t]$.

(b) $C(t) = \frac{1}{t} \left[A + \int_0^t f(s) ds \right] = \frac{A + F(t)}{t}$ represents the average expenditure per unit of t during the interval $[0, t]$, assuming that there has been only one overhaul during that time period. The company wants to minimize average expenditure.

(c) $C(t) = \frac{1}{t} \left[A + \int_0^t f(s) ds \right]$. Using FTC1, we have $C'(t) = -\frac{1}{t^2} \left[A + \int_0^t f(s) ds \right] + \frac{1}{t} f(t)$.

$$C'(t) = 0 \Rightarrow t f(t) = A + \int_0^t f(s) ds \Rightarrow f(t) = \frac{1}{t} \left[A + \int_0^t f(s) ds \right] = C(t).$$

62. (a) $C(t) = \frac{1}{t} \int_0^t [f(s) + g(s)] ds$. Using FTC1 and the Product Rule, we have

$$C'(t) = \frac{1}{t} [f(t) + g(t)] - \frac{1}{t^2} \int_0^t [f(s) + g(s)] ds. \text{ Set } C'(t) = 0:$$

$$\frac{1}{t} [f(t) + g(t)] - \frac{1}{t^2} \int_0^t [f(s) + g(s)] ds = 0 \Rightarrow [f(t) + g(t)] - \frac{1}{t} \int_0^t [f(s) + g(s)] ds = 0 \Rightarrow$$

$$[f(t) + g(t)] - C(t) = 0 \Rightarrow C(t) = f(t) + g(t).$$

(b) For $0 \leq t \leq 30$, we have $D(t) = \int_0^t \left(\frac{V}{15} - \frac{V}{450}s \right) ds = \left[\frac{V}{15}s - \frac{V}{900}s^2 \right]_0^t = \frac{V}{15}t - \frac{V}{900}t^2$.

$$\text{So } D(t) = V \Rightarrow \frac{V}{15}t - \frac{V}{900}t^2 = V \Rightarrow 60t - t^2 = 900 \Rightarrow t^2 - 60t + 900 = 0 \Rightarrow$$

$$(t - 30)^2 = 0 \Rightarrow t = 30. \text{ So the length of time } T \text{ is 30 months.}$$

(c) $C(t) = \frac{1}{t} \int_0^t \left(\frac{V}{15} - \frac{V}{450}s + \frac{V}{12,900}s^2 \right) ds = \frac{1}{t} \left[\frac{V}{15}s - \frac{V}{900}s^2 + \frac{V}{38,700}s^3 \right]_0^t$

$$= \frac{1}{t} \left(\frac{V}{15}t - \frac{V}{900}t^2 + \frac{V}{38,700}t^3 \right) = \frac{V}{15} - \frac{V}{900}t + \frac{V}{38,700}t^2 \Rightarrow$$

$$C'(t) = -\frac{V}{900} + \frac{V}{19,350}t = 0 \text{ when } \frac{1}{19,350}t = \frac{1}{900} \Rightarrow t = 21.5.$$

$$C(21.5) = \frac{V}{15} - \frac{V}{900}(21.5) + \frac{V}{38,700}(21.5)^2 \approx 0.05472V, C(0) = \frac{V}{15} \approx 0.06667V, \text{ and}$$

$$C(30) = \frac{V}{15} - \frac{V}{900}(30) + \frac{V}{38,700}(30)^2 \approx 0.05659V, \text{ so the absolute minimum is } C(21.5) \approx 0.05472V.$$

(d) As in part (c), we have $C(t) = \frac{V}{15} - \frac{V}{900}t + \frac{V}{38,700}t^2$, so $C(t) = f(t) + g(t)$

$$\Leftrightarrow \frac{V}{15} - \frac{V}{900}t + \frac{V}{38,700}t^2 = \frac{V}{15} - \frac{V}{450}t + \frac{V}{12,900}t^2 \Leftrightarrow$$

$$t^2 \left(\frac{1}{12,900} - \frac{1}{38,700} \right) = t \left(\frac{1}{450} - \frac{1}{900} \right) \Leftrightarrow$$

$$t = \frac{1/900}{2/38,700} = \frac{43}{2} = 21.5. \text{ This is the value of } t \text{ that we obtained as the critical}$$

number of C in part (c), so we have verified the result of (a) in this case.

$$63. \int_1^9 \frac{1}{2x} dx = \frac{1}{2} \int_1^9 \frac{1}{x} dx = \frac{1}{2} [\ln |x|]_1^9 = \frac{1}{2} (\ln 9 - \ln 1) = \frac{1}{2} \ln 9 - 0 = \ln 9^{1/2} = \ln 3$$

$$64. \int_0^1 10^x dx = \left[\frac{10^x}{\ln 10} \right]_0^1 = \frac{10}{\ln 10} - \frac{1}{\ln 10} = \frac{9}{\ln 10}$$

$$65. \int_{1/2}^{\sqrt{3}/2} \frac{6}{\sqrt{1-t^2}} dt = 6 \int_{1/2}^{\sqrt{3}/2} \frac{1}{\sqrt{1-t^2}} dt = 6 [\sin^{-1} t]_{1/2}^{\sqrt{3}/2} = 6 \left[\sin^{-1} \left(\frac{\sqrt{3}}{2} \right) - \sin^{-1} \left(\frac{1}{2} \right) \right]$$

$$= 6 \left(\frac{\pi}{3} - \frac{\pi}{6} \right) = 6 \left(\frac{\pi}{6} \right) = \pi$$

$$66. \int_0^1 \frac{4}{t^2+1} dt = 4 \int_0^1 \frac{1}{1+t^2} dt = 4 [\tan^{-1} t]_0^1 = 4 (\tan^{-1} 1 - \tan^{-1} 0) = 4 \left(\frac{\pi}{4} - 0 \right) = \pi$$

$$67. \int_{-1}^1 e^{u+1} du = [e^{u+1}]_{-1}^1 = e^2 - e^0 = e^2 - 1 \quad [\text{or start with } e^{u+1} = e^u e^1]$$

$$68. \int_1^2 \frac{4+u^2}{u^3} du = \int_1^2 (4u^{-3} + u^{-1}) du = \left[-\frac{4}{2} u^{-2} + \ln |u| \right]_1^2 = \left[-\frac{2}{u^2} + \ln u \right]_1^2$$

$$= \left(-\frac{1}{2} + \ln 2 \right) - \left(-2 + \ln 1 \right) = \frac{3}{2} + \ln 2$$

5.4 Indefinite Integrals and the Net Change Theorem

$$1. \frac{d}{dx} [\sqrt{x^2+1} + C] = \frac{d}{dx} [(x^2+1)^{1/2} + C] = \frac{1}{2}(x^2+1)^{-1/2} \cdot 2x = \frac{x}{\sqrt{x^2+1}}$$

$$2. \frac{d}{dx} [x \sin x + \cos x + C] = x \cos x + (\sin x) \cdot 1 - \sin x = x \cos x$$

$$3. \frac{d}{dx} \left[\frac{x}{a^2 \sqrt{a^2-x^2}} + C \right] = \frac{1}{a^2} \frac{\sqrt{a^2-x^2} - x(-x)/\sqrt{a^2-x^2}}{a^2-x^2} = \frac{1}{a^2} \frac{(a^2-x^2) + x^2}{(a^2-x^2)^{3/2}} = \frac{1}{\sqrt{(a^2-x^2)^3}}$$

41. The graph shows that $y = x + x^2 - x^4$ has x -intercepts at $x = 0$ and at $x = a \approx 1.32$. So the area of the region that lies under the curve and above the x -axis is

$$\begin{aligned}\int_0^a (x + x^2 - x^4) dx &= \left[\frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{5}x^5 \right]_0^a \\ &= \left(\frac{1}{2}a^2 + \frac{1}{3}a^3 - \frac{1}{5}a^5 \right) - 0 \\ &\approx 0.84\end{aligned}$$

42. The graph shows that $y = 2x + 3x^4 - 2x^6$ has x -intercepts at $x = 0$ and at $x = a \approx 1.37$. So the area of the region that lies under the curve and above the x -axis is

$$\begin{aligned}\int_0^a (2x + 3x^4 - 2x^6) dx &= \left[x^2 + \frac{3}{5}x^5 - \frac{2}{7}x^7 \right]_0^a \\ &= \left(a^2 + \frac{3}{5}a^5 - \frac{2}{7}a^7 \right) - 0 \\ &\approx 2.18\end{aligned}$$

43. $A = \int_0^2 (2y - y^2) dy = \left[y^2 - \frac{1}{3}y^3 \right]_0^2 = \left(4 - \frac{8}{3} \right) - 0 = \frac{4}{3}$
44. $y = \sqrt[4]{x} \Rightarrow x = y^4$, so $A = \int_0^1 y^4 dy = \left[\frac{1}{5}y^5 \right]_0^1 = \frac{1}{5}$.
45. If $w'(t)$ is the rate of change of weight in pounds per year, then $w(t)$ represents the weight in pounds of the child at age t . We know from the Net Change Theorem that $\int_5^{10} w'(t) dt = w(10) - w(5)$, so the integral represents the increase in the child's weight (in pounds) between the ages of 5 and 10.
46. $\int_a^b I(t) dt = \int_a^b Q'(t) dt = Q(b) - Q(a)$ by the Net Change Theorem, so it represents the change in the charge Q from time $t = a$ to $t = b$.
47. Since $r(t)$ is the rate at which oil leaks, we can write $r(t) = -V'(t)$, where $V(t)$ is the volume of oil at time t . [Note that the minus sign is needed because V is decreasing, so $V'(t)$ is negative, but $r(t)$ is positive.] Thus, by the Net Change Theorem, $\int_0^{120} r(t) dt = -\int_0^{120} V'(t) dt = -[V(120) - V(0)] = V(0) - V(120)$, which is the number of gallons of oil that leaked from the tank in the first two hours (120 minutes).
48. By the Net Change Theorem, $\int_0^{15} n'(t) dt = n(15) - n(0) = n(15) - 100$ represents the increase in the bee population in 15 weeks. So $100 + \int_0^{15} n'(t) dt = n(15)$ represents the total bee population after 15 weeks.
49. By the Net Change Theorem, $\int_{1000}^{5000} R'(x) dx = R(5000) - R(1000)$, so it represents the increase in revenue when production is increased from 1000 units to 5000 units.
50. The slope of the trail is the rate of change of the elevation E , so $f(x) = E'(x)$. By the Net Change Theorem, $\int_3^5 f(x) dx = \int_3^5 E'(x) dx = E(5) - E(3)$ is the change in the elevation E between $x = 3$ miles and $x = 5$ miles from the start of the trail.
51. In general, the unit of measurement for $\int_a^b f(x) dx$ is the product of the unit for $f(x)$ and the unit for x . Since $f(x)$ is measured in newtons and x is measured in meters, the units for $\int_0^{100} f(x) dx$ are newton-meters. (A newton-meter is abbreviated N-m and is called a joule.)
52. The units for $a(x)$ are pounds per foot and the units for x are feet, so the units for da/dx are pounds per foot per foot, denoted (lb/ft)/ft. The unit of measurement for $\int_2^8 a(x) dx$ is the product of pounds per foot and feet; that is, pounds.

$$53. (a) \text{ displacement} = \int_0^3 (3t - 5) dt = \left[\frac{3}{2}t^2 - 5t \right]_0^3 = \frac{27}{2} - 15 = -\frac{3}{2} \text{ m}$$

$$(b) \text{ distance traveled} = \int_0^3 |3t - 5| dt = \int_0^{5/3} (5 - 3t) dt + \int_{5/3}^3 (3t - 5) dt$$

$$= \left[5t - \frac{3}{2}t^2 \right]_0^{5/3} + \left[\frac{3}{2}t^2 - 5t \right]_{5/3}^3 = \frac{25}{3} - \frac{3}{2} \cdot \frac{25}{9} + \frac{27}{2} - 15 - \left(\frac{3}{2} \cdot \frac{25}{9} - \frac{25}{3} \right) = \frac{41}{6} \text{ m}$$

$$54. (a) \text{ displacement} = \int_1^6 (t^2 - 2t - 8) dt = \left[\frac{1}{3}t^3 - t^2 - 8t \right]_1^6 = (72 - 36 - 48) - \left(\frac{1}{3} - 1 - 8 \right) = -\frac{10}{3} \text{ m}$$

$$(b) \text{ distance traveled} = \int_1^6 |t^2 - 2t - 8| dt = \int_1^6 |(t - 4)(t + 2)| dt$$

$$= \int_1^4 (-t^2 + 2t + 8) dt + \int_4^6 (t^2 - 2t - 8) dt = \left[-\frac{1}{3}t^3 + t^2 + 8t \right]_1^4 + \left[\frac{1}{3}t^3 - t^2 - 8t \right]_4^6$$

$$= \left(-\frac{64}{3} + 16 + 32 \right) - \left(-\frac{1}{3} + 1 + 8 \right) + (72 - 36 - 48) - \left(\frac{64}{3} - 16 - 32 \right) = \frac{98}{3} \text{ m}$$

$$55. (a) v'(t) = a(t) = t + 4 \Rightarrow v(t) = \frac{1}{2}t^2 + 4t + C \Rightarrow v(0) = C = 5 \Rightarrow v(t) = \frac{1}{2}t^2 + 4t + 5 \text{ m/s}$$

$$(b) \text{ distance traveled} = \int_0^{10} |v(t)| dt = \int_0^{10} \left| \frac{1}{2}t^2 + 4t + 5 \right| dt = \int_0^{10} \left(\frac{1}{2}t^2 + 4t + 5 \right) dt$$

$$= \left[\frac{1}{6}t^3 + 2t^2 + 5t \right]_0^{10} = \frac{500}{3} + 200 + 50 = 416\frac{2}{3} \text{ m}$$

$$56. (a) v'(t) = a(t) = 2t + 3 \Rightarrow v(t) = t^2 + 3t + C \Rightarrow v(0) = C = -4 \Rightarrow v(t) = t^2 + 3t - 4$$

$$(b) \text{ distance traveled} = \int_0^3 |t^2 + 3t - 4| dt = \int_0^3 |(t + 4)(t - 1)| dt$$

$$= \int_0^1 (-t^2 - 3t + 4) dt + \int_1^3 (t^2 + 3t - 4) dt$$

$$= \left[-\frac{1}{3}t^3 - \frac{3}{2}t^2 + 4t \right]_0^1 + \left[\frac{1}{3}t^3 + \frac{3}{2}t^2 - 4t \right]_1^3$$

$$= \left(-\frac{1}{3} - \frac{3}{2} + 4 \right) + \left(9 + \frac{27}{2} - 12 \right) - \left(\frac{1}{3} + \frac{3}{2} - 4 \right) = \frac{89}{6} \text{ m}$$

$$57. \text{ Since } m'(x) = \rho(x), m = \int_0^4 \rho(x) dx = \int_0^4 (9 + 2\sqrt{x}) dx = \left[9x + \frac{4}{3}x^{3/2} \right]_0^4 = 36 + \frac{32}{3} - 0 = \frac{140}{3} = 46\frac{2}{3} \text{ kg.}$$

58. By the Net Change Theorem, the amount of water that flows from the tank is

$$\int_0^{10} r(t) dt = \int_0^{10} (200 - 4t) dt = [200t - 2t^2]_0^{10} = (2000 - 200) - 0 = 1800 \text{ liters.}$$

59. Let s be the position of the car. We know from Equation 2 that $s(100) - s(0) = \int_0^{100} v(t) dt$. We use the Midpoint Rule for $0 \leq t \leq 100$ with $n = 5$. Note that the length of each of the five time intervals is

$$20 \text{ seconds} = \frac{20}{3600} \text{ hour} = \frac{1}{180} \text{ hour. So the distance traveled is}$$

$$\int_0^{100} v(t) dt \approx \frac{1}{180} [v(10) + v(30) + v(50) + v(70) + v(90)]$$

$$= \frac{1}{180} (38 + 58 + 51 + 53 + 47)$$

$$= \frac{247}{180} \approx 1.4 \text{ miles}$$

60. (a) By the Net Change Theorem, the total amount spewed into the atmosphere is

$$Q(6) - Q(0) = \int_0^6 r(t) dt = Q(6) \text{ since } Q(0) = 0. \text{ The rate } r(t) \text{ is positive, so } Q \text{ is an increasing function.}$$

$$\text{Thus, an upper estimate for } Q(6) \text{ is } R_6 \text{ and a lower estimate for } Q(6) \text{ is } L_6. \quad \Delta t = \frac{b-a}{n} = \frac{6-0}{6} = 1.$$

$$R_6 = \sum_{i=1}^6 r(t_i) \Delta t = 10 + 24 + 36 + 46 + 54 + 60 = 230 \text{ tonnes.}$$

$$L_6 = \sum_{i=1}^6 r(t_{i-1}) \Delta t = R_6 + r(0) - r(6) = 230 + 2 - 60 = 172 \text{ tonnes.}$$

$$(b) \Delta t = \frac{b-a}{n} = \frac{6-0}{3} = 2.$$

$$Q(6) \approx M_3 = 2[r(1) + r(3) + r(5)] = 2(10 + 36 + 54) = 2(100) = 200 \text{ tonnes.}$$

61. From the Net Change Theorem, the increase in cost if the production level is raised from 2000 yards to 4000 yards

$$\text{is } C(4000) - C(2000) = \int_{2000}^{4000} C'(x) dx.$$

$$\begin{aligned} \int_{2000}^{4000} C'(x) dx &= \int_{2000}^{4000} (3 - 0.01x + 0.000006x^2) dx \\ &= [3x - 0.005x^2 + 0.000002x^3]_{2000}^{4000} = 60,000 - 2,000 = \$58,000 \end{aligned}$$

62. By the Net Change Theorem, the amount of water after four days is

$$\begin{aligned} 25,000 + \int_0^4 r(t) dt &\approx 25,000 + M_4 \\ &= 25,000 + \frac{4-0}{4} [r(0.5) + r(1.5) + r(2.5) + r(3.5)] \\ &\approx 25,000 + [1500 + 1770 + 740 + (-690)] = 28,320 \text{ liters} \end{aligned}$$

63. (a) We can find the area between the Lorenz curve and the line $y = x$ by subtracting the area under $y = L(x)$ from the area under $y = x$. Thus,

$$\begin{aligned} \text{coefficient of inequality} &= \frac{\text{area between Lorenz curve and line } y = x}{\text{area under line } y = x} = \frac{\int_0^1 [x - L(x)] dx}{\int_0^1 x dx} \\ &= \frac{\int_0^1 [x - L(x)] dx}{[x^2/2]_0^1} = \frac{\int_0^1 [x - L(x)] dx}{1/2} = 2 \int_0^1 [x - L(x)] dx \end{aligned}$$

(b) $L(x) = \frac{5}{12}x^2 + \frac{7}{12}x \Rightarrow L(50\%) = L(\frac{1}{2}) = \frac{5}{48} + \frac{7}{24} = \frac{19}{48} = 0.3958\bar{3}$, so the bottom 50% of the households receive at most about 40% of the income. Using the result in part (a),

$$\begin{aligned} \text{coefficient of inequality} &= 2 \int_0^1 [x - L(x)] dx = 2 \int_0^1 (x - \frac{5}{12}x^2 - \frac{7}{12}x) dx \\ &= 2 \int_0^1 (\frac{5}{12}x - \frac{5}{12}x^2) dx = 2 \int_0^1 \frac{5}{12}(x - x^2) dx \\ &= \frac{5}{6} [\frac{1}{2}x^2 - \frac{1}{3}x^3]_0^1 = \frac{5}{6} (\frac{1}{2} - \frac{1}{3}) = \frac{5}{6} (\frac{1}{6}) = \frac{5}{36} \end{aligned}$$

64. (a) From Exercise 4.1.66(a), $v(t) = 0.00146t^3 - 0.11553t^2 + 24.98169t - 21.26872$.

$$(b) h(125) - h(0) = \int_0^{125} v(t) dt = [0.000365t^4 - 0.03851t^3 + 12.490845t^2 - 21.26872t]_0^{125} \approx 206,407 \text{ ft}$$

$$\begin{aligned} 65. \int_1^e \frac{x^2 + x + 1}{x} dx &= \int_1^e \left(x + 1 + \frac{1}{x} \right) dx = [\frac{1}{2}x^2 + x + \ln|x|]_1^e \\ &= (\frac{1}{2}e^2 + e + \ln e) - (\frac{1}{2} + 1 + \ln 1) = \frac{1}{2}e^2 + e - \frac{1}{2} \end{aligned}$$

$$\begin{aligned} 66. \int_4^9 \left(\sqrt{x} + \frac{1}{\sqrt{x}} \right)^2 dx &= \int_4^9 \left(x + 2 + \frac{1}{x} \right) dx = [\frac{1}{2}x^2 + 2x + \ln|x|]_4^9 \\ &= \frac{81}{2} + 18 + \ln 9 - (8 + 8 + \ln 4) = \frac{85}{2} + \ln \frac{9}{4} \end{aligned}$$

$$67. \int \left(x^2 + 1 + \frac{1}{x^2 + 1} \right) dx = \frac{x^3}{3} + x + \tan^{-1} x + C$$

$$\begin{aligned} 68. B = 3A &\Rightarrow \int_0^b e^x dx = 3 \int_0^a e^x dx \Rightarrow [e^x]_0^b = 3[e^x]_0^a \Rightarrow e^b - 1 = 3(e^a - 1) \Rightarrow \\ e^b &= 3e^a - 2 \Rightarrow b = \ln(3e^a - 2) \end{aligned}$$

5.5 The Substitution Rule

1. Let $u = 3x$. Then $du = 3 dx$, so $dx = \frac{1}{3} du$. Thus,

$\int \cos 3x dx = \int \cos u \left(\frac{1}{3} du\right) = \frac{1}{3} \int \cos u du = \frac{1}{3} \sin u + C = \frac{1}{3} \sin 3x + C$. Don't forget that it is often very easy to check an indefinite integration by differentiating your answer. In this case,

$$\frac{d}{dx} \left(\frac{1}{3} \sin 3x + C \right) = \frac{1}{3} (\cos 3x) \cdot 3 = \cos 3x, \text{ the desired result.}$$

2. Let $u = 4 + x^2$. Then $du = 2x dx$ and $x dx = \frac{1}{2} du$, so

$$\int x(4 + x^2)^{10} dx = \int u^{10} \left(\frac{1}{2} du\right) = \frac{1}{2} \cdot \frac{1}{11} u^{11} + C = \frac{1}{22} (4 + x^2)^{11} + C.$$

3. Let $u = x^3 + 1$. Then $du = 3x^2 dx$ and $x^2 dx = \frac{1}{3} du$, so

$$\int x^2 \sqrt{x^3 + 1} dx = \int \sqrt{u} \left(\frac{1}{3} du\right) = \frac{1}{3} \frac{u^{3/2}}{3/2} + C = \frac{1}{3} \cdot \frac{2}{3} u^{3/2} + C = \frac{2}{9} (x^3 + 1)^{3/2} + C.$$

4. Let $u = \sqrt{x}$. Then $du = \frac{1}{2\sqrt{x}} dx$ and $\frac{1}{\sqrt{x}} dx = 2 du$, so

$$\int \frac{\sin \sqrt{x}}{\sqrt{x}} dx = \int \sin u (2 du) = 2(-\cos u) + C = -2 \cos \sqrt{x} + C.$$

5. Let $u = 1 + 2x$. Then $du = 2 dx$ and $dx = \frac{1}{2} du$, so

$$\int \frac{4}{(1 + 2x)^3} dx = 4 \int u^{-3} \left(\frac{1}{2} du\right) = 2 \frac{u^{-2}}{-2} + C = -\frac{1}{u^2} + C = -\frac{1}{(1 + 2x)^2} + C.$$

6. Let $u = \cos \theta$. Then $du = -\sin \theta d\theta$ and $\sin \theta d\theta = -du$, so

$$\int \cos^4 \theta \sin \theta d\theta = \int u^4 (-du) = -\frac{1}{5} u^5 + C = -\frac{1}{5} \cos^5 \theta + C.$$

7. Let $u = x^2 + 3$. Then $du = 2x dx$, so $\int 2x(x^2 + 3)^4 dx = \int u^4 du = \frac{1}{5} u^5 + C = \frac{1}{5} (x^2 + 3)^5 + C$.

8. Let $u = x^3 + 5$. Then $du = 3x^2 dx$ and $x^2 dx = \frac{1}{3} du$, so

$$\int x^2 (x^3 + 5)^9 dx = \int u^9 \left(\frac{1}{3} du\right) = \frac{1}{3} \cdot \frac{1}{10} u^{10} + C = \frac{1}{30} (x^3 + 5)^{10} + C.$$

9. Let $u = 3x - 2$. Then $du = 3 dx$ and $dx = \frac{1}{3} du$, so

$$\int (3x - 2)^{20} dx = \int u^{20} \left(\frac{1}{3} du\right) = \frac{1}{3} \cdot \frac{1}{21} u^{21} + C = \frac{1}{63} (3x - 2)^{21} + C.$$

10. Let $u = 2 - x$. Then $du = -dx$ and $dx = -du$, so

$$\int (2 - x)^6 dx = \int u^6 (-du) = -\frac{1}{7} u^7 + C = -\frac{1}{7} (2 - x)^7 + C.$$

11. Let $u = 1 + x + 2x^2$. Then $du = (1 + 4x) dx$, so

$$\int \frac{1 + 4x}{\sqrt{1 + x + 2x^2}} dx = \int \frac{du}{\sqrt{u}} = \int u^{-1/2} du = \frac{u^{1/2}}{1/2} + C = 2\sqrt{1 + x + 2x^2} + C.$$

12. Let $u = x^2 + 1$. Then $du = 2x dx$ and $x dx = \frac{1}{2} du$, so

$$\int \frac{x}{(x^2 + 1)^2} dx = \int u^{-2} \left(\frac{1}{2} du\right) = \frac{1}{2} \cdot \frac{-1}{u} + C = \frac{-1}{2u} + C = \frac{-1}{2(x^2 + 1)} + C.$$

13. Let $u = 2y + 1$. Then $du = 2 dy$ and $dy = \frac{1}{2} du$, so

$$\int \frac{3}{(2y + 1)^5} dy = \int 3u^{-5} \left(\frac{1}{2} du\right) = \frac{3}{2} \cdot \frac{1}{-4} u^{-4} + C = \frac{-3}{8(2y + 1)^4} + C.$$

14. Let $u = 5t + 4$. Then $du = 5 dt$ and $dt = \frac{1}{5} du$, so

$$\int \frac{1}{(5t+4)^{2.7}} dt = \int u^{-2.7} \left(\frac{1}{5} du\right) = \frac{1}{5} \cdot \frac{1}{-1.7} u^{-1.7} + C = \frac{-1}{8.5} u^{-1.7} + C = \frac{-2}{17(5t+4)^{1.7}} + C.$$

15. Let $u = 4 - t$. Then $du = -dt$ and $dt = -du$, so

$$\int \sqrt{4-t} dt = \int u^{1/2} (-du) = -\frac{2}{3} u^{3/2} + C = -\frac{2}{3} (4-t)^{3/2} + C.$$

16. Let $u = 2y^4 - 1$. Then $du = 8y^3 dy$ and $y^3 dy = \frac{1}{8} du$, so

$$\int y^3 \sqrt{2y^4 - 1} dy = \int u^{1/2} \left(\frac{1}{8} du\right) = \frac{1}{8} \cdot \frac{2}{3} u^{3/2} + C = \frac{1}{12} (2y^4 - 1)^{3/2} + C.$$

17. Let $u = \pi t$. Then $du = \pi dt$ and $dt = \frac{1}{\pi} du$, so

$$\int \sin \pi t dt = \int \sin u \left(\frac{1}{\pi} du\right) = \frac{1}{\pi} (-\cos u) + C = -\frac{1}{\pi} \cos \pi t + C.$$

18. Let $u = 2\theta$. Then $du = 2 d\theta$ and $d\theta = \frac{1}{2} du$, so

$$\int \sec 2\theta \tan 2\theta d\theta = \int \sec u \tan u \left(\frac{1}{2} du\right) = \frac{1}{2} \sec u + C = \frac{1}{2} \sec 2\theta + C.$$

19. Let $u = \sqrt{t}$. Then $du = \frac{dt}{2\sqrt{t}}$ and $\frac{1}{\sqrt{t}} dt = 2 du$, so

$$\int \frac{\cos \sqrt{t}}{\sqrt{t}} dt = \int \cos u (2 du) = 2 \sin u + C = 2 \sin \sqrt{t} + C.$$

20. Let $u = 1 + x^{3/2}$. Then $du = \frac{3}{2} x^{1/2} dx$ and $\sqrt{x} dx = \frac{2}{3} du$, so

$$\int \sqrt{x} \sin(1 + x^{3/2}) dx = \int \sin u \left(\frac{2}{3} du\right) = \frac{2}{3} \cdot (-\cos u) + C = -\frac{2}{3} \cos(1 + x^{3/2}) + C.$$

21. Let $u = \sin \theta$. Then $du = \cos \theta d\theta$, so $\int \cos \theta \sin^6 \theta d\theta = \int u^6 du = \frac{1}{7} u^7 + C = \frac{1}{7} \sin^7 \theta + C.$

22. Let $u = 1 + \tan \theta$. Then $du = \sec^2 \theta d\theta$, so

$$\int (1 + \tan \theta)^5 \sec^2 \theta d\theta = \int u^5 du = \frac{1}{6} u^6 + C = \frac{1}{6} (1 + \tan \theta)^6 + C.$$

23. Let $u = 1 + z^3$. Then $du = 3z^2 dz$ and $z^2 dz = \frac{1}{3} du$, so

$$\int \frac{z^2}{\sqrt[3]{1+z^3}} dz = \int u^{-1/3} \left(\frac{1}{3} du\right) = \frac{1}{3} \cdot \frac{3}{2} u^{2/3} + C = \frac{1}{2} (1 + z^3)^{2/3} + C.$$

24. Let $u = ax^2 + 2bx + c$. Then $du = 2(ax + b) dx$ and $(ax + b) dx = \frac{1}{2} du$, so

$$\int \frac{(ax+b) dx}{\sqrt{ax^2+2bx+c}} = \int \frac{\frac{1}{2} du}{\sqrt{u}} = \frac{1}{2} \int u^{-1/2} du = u^{1/2} + C = \sqrt{ax^2+2bx+c} + C.$$

25. Let $u = \cot x$. Then $du = -\csc^2 x dx$ and $\csc^2 x dx = -du$, so

$$\int \sqrt{\cot x} \csc^2 x dx = \int \sqrt{u} (-du) = -\frac{u^{3/2}}{3/2} + C = -\frac{2}{3} (\cot x)^{3/2} + C.$$

26. Let $u = \frac{\pi}{x}$. Then $du = -\frac{\pi}{x^2} dx$ and $\frac{1}{x^2} dx = -\frac{1}{\pi} du$, so

$$\int \frac{\cos(\pi/x)}{x^2} dx = \int \cos u \left(-\frac{1}{\pi} du\right) = -\frac{1}{\pi} \sin u + C = -\frac{1}{\pi} \sin \frac{\pi}{x} + C.$$

27. Let $u = \sec x$. Then $du = \sec x \tan x dx$, so

$$\int \sec^3 x \tan x dx = \int \sec^2 x (\sec x \tan x) dx = \int u^2 du = \frac{1}{3} u^3 + C = \frac{1}{3} \sec^3 x + C.$$

28. Let $u = x^3 + 1$. Then $x^3 = u - 1$ and $du = 3x^2 dx$, so

$$\begin{aligned}\int \sqrt[3]{x^3 + 1} x^5 dx &= \int \sqrt[3]{x^3 + 1} \cdot x^3 \cdot x^2 dx = \int u^{1/3} (u - 1) \left(\frac{1}{3} du\right) = \frac{1}{3} \int (u^{4/3} - u^{1/3}) du \\ &= \frac{1}{3} \left(\frac{3}{7} u^{7/3} - \frac{3}{4} u^{4/3} \right) + C = \frac{1}{7} (x^3 + 1)^{7/3} - \frac{1}{4} (x^3 + 1)^{4/3} + C\end{aligned}$$

29. Let $u = b + cx^{a+1}$. Then $du = (a + 1)cx^a dx$, so

$$\int x^a \sqrt{b + cx^{a+1}} dx = \int u^{1/2} \frac{1}{(a + 1)c} du = \frac{1}{(a + 1)c} \left(\frac{2}{3} u^{3/2} \right) + C = \frac{2}{3c(a + 1)} (b + cx^{a+1})^{3/2} + C.$$

30. Let $u = \cos t$. Then $du = -\sin t dt$ and $\sin t dt = -du$, so

$$\int \sin t \sec^2(\cos t) dt = \int \sec^2 u \cdot (-du) = -\tan u + C = -\tan(\cos t) + C.$$

31. Let $u = x + 2$. Then $du = dx$, so

$$\begin{aligned}\int \frac{x}{\sqrt[4]{x+2}} dx &= \int \frac{u-2}{\sqrt[4]{u}} du = \int (u^{3/4} - 2u^{-1/4}) du = \frac{4}{7} u^{7/4} - 2 \cdot \frac{4}{3} u^{3/4} + C \\ &= \frac{4}{7} (x+2)^{7/4} - \frac{8}{3} (x+2)^{3/4} + C\end{aligned}$$

32. Let $u = 1 - x$. Then $x = 1 - u$ and $dx = -du$, so

$$\begin{aligned}\int \frac{x^2}{\sqrt{1-x}} dx &= \int \frac{(1-u)^2}{\sqrt{u}} (-du) = -\int \frac{1-2u+u^2}{\sqrt{u}} du = -\int (u^{-1/2} - 2u^{1/2} + u^{3/2}) du \\ &= -\left(2u^{1/2} - 2 \cdot \frac{2}{3} u^{3/2} + \frac{2}{5} u^{5/2} \right) + C = -2\sqrt{1-x} + \frac{4}{3}(1-x)^{3/2} - \frac{2}{5}(1-x)^{5/2} + C\end{aligned}$$

In Exercises 33–36, let $f(x)$ denote the integrand and $F(x)$ its antiderivative (with $C = 0$).

33. $f(x) = \frac{3x-1}{(3x^2-2x+1)^4}.$

$u = 3x^2 - 2x + 1 \Rightarrow du = (6x - 2) dx = 2(3x - 1) dx$, so

$$\begin{aligned}\int \frac{3x-1}{(3x^2-2x+1)^4} dx &= \int \frac{1}{u^4} \left(\frac{1}{2} du \right) = \frac{1}{2} \int u^{-4} du \\ &= -\frac{1}{6} u^{-3} + C = -\frac{1}{6(3x^2-2x+1)^3} + C\end{aligned}$$

Notice that at $x = \frac{1}{3}$, f changes from negative to positive, and F has a local minimum.

34. $f(x) = \frac{x}{\sqrt{x^2+1}}, u = x^2 + 1 \Rightarrow du = 2x dx$, so

$$\begin{aligned}\int \frac{x}{\sqrt{x^2+1}} dx &= \int \frac{1}{\sqrt{u}} \left(\frac{1}{2} du \right) = \frac{1}{2} \int u^{-1/2} du \\ &= u^{1/2} + C = \sqrt{x^2+1} + C.\end{aligned}$$

Note that at $x = 0$, f changes from negative to positive and F has a local minimum.

35. $f(x) = \sin^3 x \cos x$. $u = \sin x \Rightarrow du = \cos x dx$, so

$$\int \sin^3 x \cos x dx = \int u^3 du = \frac{1}{4}u^4 + C = \frac{1}{4}\sin^4 x + C$$

Note that at $x = \frac{\pi}{2}$, f changes from positive to negative and F has a local maximum. Also, both f and F are periodic with period π , so at $x = 0$ and at $x = \pi$, f changes from negative to positive and F has local minima.

36. $f(\theta) = \tan^2 \theta \sec^2 \theta$. $u = \tan \theta \Rightarrow du = \sec^2 \theta d\theta$, so

$$\int \tan^2 \theta \sec^2 \theta d\theta = \int u^2 du = \frac{1}{3}u^3 + C = \frac{1}{3}\tan^3 \theta + C$$

Note that f is positive and F is increasing. At $x = 0$, $f = 0$ and F has a horizontal tangent.

37. Let $u = x - 1$, so $du = dx$. When $x = 0$, $u = -1$; when $x = 2$, $u = 1$. Thus, $\int_0^2 (x-1)^{25} dx = \int_{-1}^1 u^{25} du = 0$ by Theorem 6(b), since $f(u) = u^{25}$ is an odd function.

38. Let $u = 4 + 3x$, so $du = 3 dx$. When $x = 0$, $u = 4$; when $x = 7$, $u = 25$. Thus,

$$\int_0^7 \sqrt{4+3x} dx = \int_4^{25} \sqrt{u} \left(\frac{1}{3} du\right) = \frac{1}{3} \left[\frac{u^{3/2}}{3/2} \right]_4^{25} = \frac{2}{9} (25^{3/2} - 4^{3/2}) = \frac{2}{9} (125 - 8) = \frac{234}{9} = 26$$

39. Let $u = 1 + 2x^3$, so $du = 6x^2 dx$. When $x = 0$, $u = 1$; when $x = 1$, $u = 3$. Thus,

$$\int_0^1 x^2 (1 + 2x^3)^5 dx = \int_1^3 u^5 \left(\frac{1}{6} du\right) = \frac{1}{6} \left[\frac{u^6}{6} \right]_1^3 = \frac{1}{36} (3^6 - 1^6) = \frac{1}{36} (729 - 1) = \frac{728}{36} = \frac{182}{9}$$

40. Let $u = x^2$, so $du = 2x dx$. When $x = 0$, $u = 0$; when $x = \sqrt{\pi}$, $u = \pi$. Thus,

$$\int_0^{\sqrt{\pi}} x \cos(x^2) dx = \int_0^{\pi} \cos u \left(\frac{1}{2} du\right) = \frac{1}{2} [\sin u]_0^{\pi} = \frac{1}{2} (\sin \pi - \sin 0) = \frac{1}{2} (0 - 0) = 0.$$

41. Let $u = t/4$, so $du = \frac{1}{4} dt$. When $t = 0$, $u = 0$; when $t = \pi$, $u = \pi/4$. Thus,

$$\int_0^{\pi} \sec^2(t/4) dt = \int_0^{\pi/4} \sec^2 u (4 du) = 4 [\tan u]_0^{\pi/4} = 4 (\tan \frac{\pi}{4} - \tan 0) = 4(1 - 0) = 4.$$

42. Let $u = \pi t$, so $du = \pi dt$. When $t = \frac{1}{6}$, $u = \frac{\pi}{6}$; when $t = \frac{1}{2}$, $u = \frac{\pi}{2}$. Thus,

$$\int_{1/6}^{1/2} \csc \pi t \cot \pi t dt = \int_{\pi/6}^{\pi/2} \csc u \cot u \left(\frac{1}{\pi} du\right) = \frac{1}{\pi} [-\csc u]_{\pi/6}^{\pi/2} = -\frac{1}{\pi} (1 - 2) = \frac{1}{\pi}.$$

43. $\int_{-\pi/6}^{\pi/6} \tan^3 \theta d\theta = 0$ by Theorem 6(b), since $f(\theta) = \tan^3 \theta$ is an odd function.

44. $\int_0^2 \frac{dx}{(2x-3)^2}$ does not exist since $f(x) = \frac{1}{(2x-3)^2}$ has an infinite discontinuity at $x = \frac{3}{2}$.

45. Let $u = \cos \theta$, so $du = -\sin \theta d\theta$. When $\theta = 0$, $u = 1$; when $\theta = \frac{\pi}{3}$, $u = \frac{1}{2}$. Thus,

$$\int_0^{\pi/3} \frac{\sin \theta}{\cos^2 \theta} d\theta = \int_1^{1/2} \frac{-du}{u^2} = \int_{1/2}^1 u^{-2} du = \left[-\frac{1}{u} \right]_{1/2}^1 = -1 - (-2) = 1.$$

46. $\int_{-\pi/2}^{\pi/2} \frac{x^2 \sin x}{1+x^6} dx = 0$ by Theorem 6(b), since $f(x) = \frac{x^2 \sin x}{1+x^6}$ is an odd function.

47. Let $u = 1 + 2x$, so $du = 2 dx$. When $x = 0$, $u = 1$; when $x = 13$, $u = 27$. Thus,

$$\int_0^{13} \frac{dx}{\sqrt[3]{(1+2x)^2}} = \int_1^{27} u^{-2/3} \left(\frac{1}{2} du\right) = \left[\frac{1}{2} \cdot 3u^{1/3} \right]_1^{27} = \frac{3}{2} (3 - 1) = 3.$$

48. Let $u = \sin x$, so $du = \cos x \, dx$. When $x = 0$, $u = 0$; when $x = \frac{\pi}{2}$, $u = 1$. Thus,

$$\int_0^{\pi/2} \cos x \sin(\sin x) \, dx = \int_0^1 \sin u \, du = [-\cos u]_0^1 = -(\cos 1 - 1) = 1 - \cos 1.$$

49. Let $u = x - 1$, so $u + 1 = x$ and $du = dx$. When $x = 1$, $u = 0$; when $x = 2$, $u = 1$. Thus,

$$\int_1^2 x \sqrt{x-1} \, dx = \int_0^1 (u+1)\sqrt{u} \, du = \int_0^1 (u^{3/2} + u^{1/2}) \, du = \left[\frac{2}{5} u^{5/2} + \frac{2}{3} u^{3/2} \right]_0^1 = \frac{2}{5} + \frac{2}{3} = \frac{16}{15}.$$

50. Let $u = 1 + 2x$, so $x = \frac{1}{2}(u - 1)$ and $du = 2 \, dx$. When $x = 0$, $u = 1$; when $x = 4$, $u = 9$. Thus,

$$\begin{aligned} \int_0^4 \frac{x \, dx}{\sqrt{1+2x}} &= \int_1^9 \frac{\frac{1}{2}(u-1)}{\sqrt{u}} \frac{du}{2} = \frac{1}{4} \int_1^9 (u^{1/2} - u^{-1/2}) \, du = \frac{1}{4} \left[\frac{2}{3} u^{3/2} - 2u^{1/2} \right]_1^9 \\ &= \frac{1}{4} \cdot \frac{2}{3} \left[u^{3/2} - 3u^{1/2} \right]_1^9 = \frac{1}{6} [(27 - 9) - (1 - 3)] = \frac{20}{6} = \frac{10}{3} \end{aligned}$$

51. $\int_0^4 \frac{dx}{(x-2)^3}$ does not exist since $f(x) = \frac{1}{(x-2)^3}$ has an infinite discontinuity at $x = 2$.

52. Assume $a > 0$. Let $u = a^2 - x^2$, so $du = -2x \, dx$. When $x = 0$, $u = a^2$; when $x = a$, $u = 0$. Thus,

$$\int_0^a x \sqrt{a^2 - x^2} \, dx = \int_{a^2}^0 u^{1/2} \left(-\frac{1}{2} du\right) = \frac{1}{2} \int_0^{a^2} u^{1/2} \, du = \frac{1}{2} \cdot \left[\frac{2}{3} u^{3/2} \right]_0^{a^2} = \frac{1}{3} a^3.$$

53. Let $u = x^2 + a^2$, so $du = 2x \, dx$ and $x \, dx = \frac{1}{2} du$. When $x = 0$, $u = a^2$; when $x = a$, $u = 2a^2$. Thus,

$$\begin{aligned} \int_0^a x \sqrt{x^2 + a^2} \, dx &= \int_{a^2}^{2a^2} u^{1/2} \left(\frac{1}{2} du\right) = \frac{1}{2} \left[\frac{2}{3} u^{3/2} \right]_{a^2}^{2a^2} = \left[\frac{1}{3} u^{3/2} \right]_{a^2}^{2a^2} \\ &= \frac{1}{3} \left[(2a^2)^{3/2} - (a^2)^{3/2} \right] = \frac{1}{3} (2\sqrt{2} - 1) a^3 \end{aligned}$$

54. $\int_{-a}^a x \sqrt{x^2 + a^2} \, dx = 0$ by Theorem 6(b), since $f(x) = x \sqrt{x^2 + a^2}$ is an odd function.

55. From the graph, it appears that the area under the curve is about

$1 + (\text{a little more than } \frac{1}{2} \cdot 1 \cdot 0.7)$, or about 1.4. The exact area is given by

$A = \int_0^1 \sqrt{2x+1} \, dx$. Let $u = 2x+1$, so $du = 2 \, dx$. The limits change to $2 \cdot 0 + 1 = 1$ and $2 \cdot 1 + 1 = 3$, and

$$A = \int_1^3 \sqrt{u} \left(\frac{1}{2} du\right) = \frac{1}{2} \left[\frac{2}{3} u^{3/2} \right]_1^3 = \frac{1}{3} (3\sqrt{3} - 1) = \sqrt{3} - \frac{1}{3} \approx 1.399.$$

56. From the graph, it appears that the area under the curve is almost

$\frac{1}{2} \cdot \pi \cdot 2.6$, or about 4. The exact area is given by

$$\begin{aligned} A &= \int_0^\pi (2 \sin x - \sin 2x) \, dx = -2 [\cos x]_0^\pi - \int_0^\pi \sin 2x \, dx \\ &= -2(-1 - 1) - 0 = 4 \end{aligned}$$

Note: $\int_0^\pi \sin 2x \, dx = 0$ since it is clear from the graph of $y = \sin 2x$

that $\int_{\pi/2}^\pi \sin 2x \, dx = -\int_0^{\pi/2} \sin 2x \, dx$.

57. First write the integral as a sum of two integrals:

$I = \int_{-2}^2 (x+3)\sqrt{4-x^2} dx = I_1 + I_2 = \int_{-2}^2 x\sqrt{4-x^2} dx + \int_{-2}^2 3\sqrt{4-x^2} dx$. $I_1 = 0$ by Theorem 6(b), since $f(x) = x\sqrt{4-x^2}$ is an odd function and we are integrating from $x = -2$ to $x = 2$. We interpret I_2 as three times the area of a semicircle with radius 2, so $I = 0 + 3 \cdot \frac{1}{2}(\pi \cdot 2^2) = 6\pi$.

58. Let $u = x^2$. Then $du = 2x dx$ and the limits are unchanged ($0^2 = 0$ and $1^2 = 1$), so

$I = \int_0^1 x\sqrt{1-x^4} dx = \frac{1}{2} \int_0^1 \sqrt{1-u^2} du$. But this integral can be interpreted as the area of a quarter-circle with radius 1. So $I = \frac{1}{2} \cdot \frac{1}{4}(\pi \cdot 1^2) = \frac{1}{8}\pi$.

59. The volume of inhaled air in the lungs at time t is

$$\begin{aligned} V(t) &= \int_0^t f(u) du = \int_0^t \frac{1}{2} \sin\left(\frac{2\pi}{5} u\right) du = \int_0^{2\pi t/5} \frac{1}{2} \sin v \left(\frac{5}{2\pi} dv\right) \quad [\text{substitute } v = \frac{2\pi}{5} u, dv = \frac{2\pi}{5} du] \\ &= \frac{5}{4\pi} [-\cos v]_0^{2\pi t/5} = \frac{5}{4\pi} [-\cos(\frac{2\pi}{5} t) + 1] = \frac{5}{4\pi} [1 - \cos(\frac{2\pi}{5} t)] \text{ liters} \end{aligned}$$

60. Number of calculators $= x(4) - x(2) = \int_2^4 5000 [1 - 100(t+10)^{-2}] dt$
 $= 5000 [t + 100(t+10)^{-1}]_2^4 = 5000 [(4 + \frac{100}{14}) - (2 + \frac{100}{12})] \approx 4048$

61. Let $u = 2x$. Then $du = 2 dx$, so $\int_0^2 f(2x) dx = \int_0^4 f(u) (\frac{1}{2} du) = \frac{1}{2} \int_0^4 f(u) du = \frac{1}{2}(10) = 5$.

62. Let $u = x^2$. Then $du = 2x dx$, so $\int_0^3 x f(x^2) dx = \int_0^9 f(u) (\frac{1}{2} du) = \frac{1}{2} \int_0^9 f(u) du = \frac{1}{2}(4) = 2$.

63. (a) Let $u = -x$. Then $du = -dx$, so

$$\int_a^b f(-x) dx = \int_{-a}^{-b} f(u)(-du) = \int_{-b}^{-a} f(u) du = \int_{-b}^{-a} f(x) dx$$

From the diagram, we see that the equality follows from the fact that we are reflecting the graph of f , and the limits of integration, about the y -axis.

(b) Let $u = x + c$. Then $du = dx$, so

$$\int_a^b f(x+c) dx = \int_{a+c}^{b+c} f(u) du = \int_{a+c}^{b+c} f(x) dx$$

From the diagram, we see that the equality follows from the fact that we are translating the graph of f , and the limits of integration, by a distance c .

64. The area under the graph of $y = \sin \sqrt{x}$ from 0 to 4 is $A_1 = \int_0^4 \sin \sqrt{x} dx$. The area under the graph of $y = 2x \sin x$ from 0 to 2 is $A_2 = \int_0^2 2x \sin x dx$ [$u = x^2$, $du = 2x dx$, $\sqrt{u} = x$ for $0 \leq x \leq 2$] $= \int_0^4 \sin \sqrt{u} du$. Since the integration variable is immaterial, $A_1 = A_2$.

65. Let $u = 1 - x$. Then $x = 1 - u$ and $dx = -du$, so

$$\int_0^1 x^a (1-x)^b dx = \int_1^0 (1-u)^a u^b (-du) = \int_0^1 u^b (1-u)^a du = \int_0^1 x^b (1-x)^a dx.$$

66. Let $u = \pi - x$. Then $du = -dx$. When $x = \pi$, $u = 0$ and when $x = 0$, $u = \pi$. So

$$\begin{aligned}\int_0^\pi x f(\sin x) dx &= -\int_\pi^0 (\pi - u) f(\sin(\pi - u)) du = \int_0^\pi (\pi - u) f(\sin u) du \\ &= \pi \int_0^\pi f(\sin u) du - \int_0^\pi u f(\sin u) du = \pi \int_0^\pi f(\sin x) dx - \int_0^\pi x f(\sin x) dx \\ \Rightarrow 2 \int_0^\pi x f(\sin x) dx &= \pi \int_0^\pi f(\sin x) dx \quad \Rightarrow \quad \int_0^\pi x f(\sin x) dx = \frac{\pi}{2} \int_0^\pi f(\sin x) dx.\end{aligned}$$

67. Let $u = 5 - 3x$. Then $du = -3 dx$ and $dx = -\frac{1}{3} du$, so

$$\int \frac{dx}{5 - 3x} = \int \frac{1}{u} \left(-\frac{1}{3} du\right) = -\frac{1}{3} \ln |u| + C = -\frac{1}{3} \ln |5 - 3x| + C.$$

68. Let $u = x^2 + 1$. Then $du = 2x dx$ and $x dx = \frac{1}{2} du$, so

$$\begin{aligned}\int \frac{x}{x^2 + 1} dx &= \int \frac{\frac{1}{2} du}{u} = \frac{1}{2} \ln |u| + C = \frac{1}{2} \ln |x^2 + 1| + C = \frac{1}{2} \ln(x^2 + 1) + C \quad [\text{since } x^2 + 1 > 0] \\ \text{or } \ln(x^2 + 1)^{1/2} + C &= \ln \sqrt{x^2 + 1} + C.\end{aligned}$$

69. Let $u = \ln x$. Then $du = \frac{dx}{x}$, so $\int \frac{(\ln x)^2}{x} dx = \int u^2 du = \frac{1}{3} u^3 + C = \frac{1}{3} (\ln x)^3 + C$.

70. Let $u = \tan^{-1} x$. Then $du = \frac{dx}{1 + x^2}$, so $\int \frac{\tan^{-1} x}{1 + x^2} dx = \int u du = \frac{u^2}{2} + C = \frac{(\tan^{-1} x)^2}{2} + C$.

71. Let $u = 1 + e^x$. Then $du = e^x dx$, so $\int e^x \sqrt{1 + e^x} dx = \int \sqrt{u} du = \frac{2}{3} u^{3/2} + C = \frac{2}{3} (1 + e^x)^{3/2} + C$.

Or: Let $u = \sqrt{1 + e^x}$. Then $u^2 = 1 + e^x$ and $2u du = e^x dx$, so

$$\int e^x \sqrt{1 + e^x} dx = \int u \cdot 2u du = \frac{2}{3} u^3 + C = \frac{2}{3} (1 + e^x)^{3/2} + C.$$

72. Let $u = \cos t$. Then $du = -\sin t dt$ and $\sin t dt = -du$, so

$$\int e^{\cos t} \sin t dt = \int e^u (-du) = -e^u + C = -e^{\cos t} + C.$$

73. Let $u = \ln x$. Then $du = \frac{dx}{x}$, so $\int \frac{dx}{x \ln x} = \int \frac{du}{u} = \ln |u| + C = \ln |\ln x| + C$.

74. Let $u = e^x + 1$. Then $du = e^x dx$, so $\int \frac{e^x}{e^x + 1} dx = \int \frac{du}{u} = \ln |u| + C = \ln(e^x + 1) + C$.

75. $\int \cot x dx = \int \frac{\cos x}{\sin x} dx$. Let $u = \sin x$. Then $du = \cos x dx$, so

$$\int \cot x dx = \int \frac{1}{u} du = \ln |u| + C = \ln |\sin x| + C.$$

76. Let $u = \cos x$. Then $du = -\sin x dx$ and $\sin x dx = -du$, so

$$\int \frac{\sin x}{1 + \cos^2 x} dx = \int \frac{-du}{1 + u^2} = -\tan^{-1} u + C = -\tan^{-1}(\cos x) + C.$$

77. Let $u = 1 + x^2$. Then $du = 2x dx$, so

$$\begin{aligned}\int \frac{1 + x}{1 + x^2} dx &= \int \frac{1}{1 + x^2} dx + \int \frac{x}{1 + x^2} dx = \tan^{-1} x + \int \frac{\frac{1}{2} du}{u} = \tan^{-1} x + \frac{1}{2} \ln |u| + C \\ &= \tan^{-1} x + \frac{1}{2} \ln |1 + x^2| + C = \tan^{-1} x + \frac{1}{2} \ln(1 + x^2) + C \quad [\text{since } 1 + x^2 > 0].\end{aligned}$$

78. Let $u = x^2$. Then $du = 2x dx$, so $\int \frac{x}{1+x^4} dx = \int \frac{\frac{1}{2} du}{1+u^2} = \frac{1}{2} \tan^{-1} u + C = \frac{1}{2} \tan^{-1}(x^2) + C$.

79. Let $u = 1/x$, so $du = -1/x^2 dx$. When $x = 1$, $u = 1$; when $x = 2$, $u = \frac{1}{2}$. Thus,

$$\int_1^2 \frac{e^{1/x}}{x^2} dx = \int_1^{1/2} e^u (-du) = -[e^u]_1^{1/2} = -(e^{1/2} - e) = e - \sqrt{e}.$$

80. Let $u = -x^2$, so $du = -2x dx$. When $x = 0$, $u = 0$; when $x = 1$, $u = -1$. Thus,

$$\int_0^1 x e^{-x^2} dx = \int_0^{-1} e^u \left(-\frac{1}{2} du\right) = -\frac{1}{2} [e^u]_0^{-1} = -\frac{1}{2} (e^{-1} - e^0) = \frac{1}{2} (1 - 1/e).$$

81. Let $u = \ln x$, so $du = \frac{dx}{x}$. When $x = e$, $u = 1$; when $x = e^4$, $u = 4$. Thus,

$$\int_e^{e^4} \frac{dx}{x \sqrt{\ln x}} = \int_1^4 u^{-1/2} du = 2[u^{1/2}]_1^4 = 2(2 - 1) = 2.$$

82. Let $u = \sin^{-1} x$, so $du = \frac{dx}{\sqrt{1-x^2}}$. When $x = 0$, $u = 0$; when $x = \frac{1}{2}$, $u = \frac{\pi}{6}$. Thus,

$$\int_0^{1/2} \frac{\sin^{-1} x}{\sqrt{1-x^2}} dx = \int_0^{\pi/6} u du = \left[\frac{u^2}{2}\right]_0^{\pi/6} = \frac{\pi^2}{72}.$$

83. $\frac{x \sin x}{1 + \cos^2 x} = x \cdot \frac{\sin x}{2 - \sin^2 x} = x f(\sin x)$, where $f(t) = \frac{t}{2 - t^2}$. By Exercise 66,

$$\int_0^\pi \frac{x \sin x}{1 + \cos^2 x} dx = \int_0^\pi x f(\sin x) dx = \frac{\pi}{2} \int_0^\pi f(\sin x) dx = \frac{\pi}{2} \int_0^\pi \frac{\sin x}{1 + \cos^2 x} dx$$

Let $u = \cos x$. Then $du = -\sin x dx$. When $x = \pi$, $u = -1$ and when $x = 0$, $u = 1$. So

$$\begin{aligned} \frac{\pi}{2} \int_0^\pi \frac{\sin x}{1 + \cos^2 x} dx &= -\frac{\pi}{2} \int_1^{-1} \frac{du}{1 + u^2} = \frac{\pi}{2} \int_{-1}^1 \frac{du}{1 + u^2} = \frac{\pi}{2} [\tan^{-1} u]_{-1}^1 \\ &= \frac{\pi}{2} [\tan^{-1} 1 - \tan^{-1}(-1)] = \frac{\pi}{2} \left[\frac{\pi}{4} - \left(-\frac{\pi}{4}\right) \right] = \frac{\pi^2}{4} \end{aligned}$$

5 Review

CONCEPT CHECK

- (a) $\sum_{i=1}^n f(x_i^*) \Delta x$ is an expression for a Riemann sum of a function f .
 x_i^* is a point in the i th subinterval $[x_{i-1}, x_i]$ and Δx is the length of the subintervals.
 (b) See Figure 1 in Section 5.2.
 (c) In Section 5.2, see Figure 3 and the paragraph beside it.
- (a) See Definition 5.2.2.
 (b) See Figure 2 in Section 5.2.
 (c) In Section 5.2, see Figure 4 and the paragraph above it.
- See the Fundamental Theorem of Calculus after Example 8 in Section 5.3.

4. (a) See the Net Change Theorem after Example 5 in Section 5.4.
 (b) $\int_{t_1}^{t_2} r(t) dt$ represents the change in the amount of water in the reservoir between time t_1 and time t_2 .
5. (a) $\int_{60}^{120} v(t) dt$ represents the change in position of the particle from $t = 60$ to $t = 120$ seconds.
 (b) $\int_{60}^{120} |v(t)| dt$ represents the total distance traveled by the particle from $t = 60$ to 120 seconds.
 (c) $\int_{60}^{120} a(t) dt$ represents the change in the velocity of the particle from $t = 60$ to $t = 120$ seconds.
6. (a) $\int f(x) dx$ is the family of functions $\{F \mid F' = f\}$. Any two such functions differ by a constant.
 (b) The connection is given by the Evaluation Theorem: $\int_a^b f(x) dx = [F(x)]_a^b$ if f is continuous.
7. The precise version of this statement is given by the Fundamental Theorem of Calculus. See the statement of this theorem and the paragraph that follows it at the end of Section 5.3.
8. See the Substitution Rule (5.5.4). This says that it is permissible to operate with the dx after an integral sign as if it were a differential.

 TRUE-FALSE QUIZ

1. True by Property 2 of the Integral in Section 5.2.
2. False. Try $a = 0$, $b = 2$, $f(x) = g(x) = 1$ as a counterexample.
3. True by Property 3 of the Integral in Section 5.2.
4. False. You can't take a variable outside the integral sign. For example, using $f(x) = 1$ on $[0, 1]$,

$$\int_0^1 x f(x) dx = \int_0^1 x dx = \left[\frac{1}{2}x^2\right]_0^1 = \frac{1}{2} \text{ (a constant) while } x \int_0^1 1 dx = x [x]_0^1 = x \cdot 1 = x \text{ (a variable).}$$
5. False. For example, let $f(x) = x^2$. Then $\int_0^1 \sqrt{x^2} dx = \int_0^1 x dx = \frac{1}{2}$, but $\sqrt{\int_0^1 x^2 dx} = \sqrt{\frac{1}{3}} = \frac{1}{\sqrt{3}}$.
6. True by the Net Change Theorem.
7. True by Comparison Property 7 of the Integral in Section 5.2.
8. False. For example, let $a = 0$, $b = 1$, $f(x) = 3$, $g(x) = x$. $f(x) > g(x)$ for each x in $(0, 1)$, but
 $f'(x) = 0 < 1 = g'(x)$ for $x \in (0, 1)$.
9. True. The integrand is an odd function that is continuous on $[-1, 1]$, so the result follows from Theorem 5.5.6(b).
10. True.
$$\int_{-5}^5 (ax^2 + bx + c) dx = \int_{-5}^5 (ax^2 + c) dx + \int_{-5}^5 bx dx$$

$$= 2 \int_0^5 (ax^2 + c) dx \text{ [by 5.5.6(a)] } + 0 \text{ [by 5.5.6(b)]}$$
11. False. The function $f(x) = 1/x^4$ is not bounded on the interval $[-2, 1]$. It has an infinite discontinuity at $x = 0$, so it is not integrable on the interval. (If the integral were to exist, a positive value would be expected, by Comparison Property 6 of Integrals.)
12. False. See the remarks and Figure 4 before Example 1 in Section 5.2, and notice that $y = x - x^3 < 0$ for $1 < x \leq 2$.
13. False. For example, the function $y = |x|$ is continuous on $\mathbb{R}$, but has no derivative at $x = 0$.
14. True by FTC1.

EXERCISES

1. (a)

$$\begin{aligned}
 L_6 &= \sum_{i=1}^6 f(x_{i-1}) \Delta x \quad [\Delta x = \frac{6-0}{6} = 1] \\
 &= f(x_0) \cdot 1 + f(x_1) \cdot 1 + f(x_2) \cdot 1 \\
 &\quad + f(x_3) \cdot 1 + f(x_4) \cdot 1 + f(x_5) \cdot 1 \\
 &\approx 2 + 3.5 + 4 + 2 + (-1) + (-2.5) = 8
 \end{aligned}$$

The Riemann sum represents the sum of the areas of the four rectangles above the x -axis minus the sum of the areas of the two rectangles below the x -axis.

(b)

$$\begin{aligned}
 M_6 &= \sum_{i=1}^6 f(\bar{x}_i) \Delta x \quad [\Delta x = \frac{6-0}{6} = 1] \\
 &= f(\bar{x}_1) \cdot 1 + f(\bar{x}_2) \cdot 1 + f(\bar{x}_3) \cdot 1 \\
 &\quad + f(\bar{x}_4) \cdot 1 + f(\bar{x}_5) \cdot 1 + f(\bar{x}_6) \cdot 1 \\
 &= f(0.5) + f(1.5) + f(2.5) + f(3.5) + f(4.5) + f(5.5) \\
 &\approx 3 + 3.9 + 3.4 + 0.3 + (-2) + (-2.9) = 5.7
 \end{aligned}$$

The Riemann sum represents the sum of the areas of the four rectangles above the x -axis minus the sum of the areas of the two rectangles below the x -axis.

2. (a)

$$f(x) = x^2 - x \text{ and } \Delta x = \frac{2-0}{4} = 0.5 \Rightarrow$$

$$\begin{aligned}
 R_4 &= 0.5f(0.5) + 0.5f(1) + 0.5f(1.5) + 0.5f(2) \\
 &= 0.5(-0.25 + 0 + 0.75 + 2) = 1.25
 \end{aligned}$$

The Riemann sum represents the sum of the areas of the two rectangles above the x -axis minus the area of the rectangle below the x -axis. (The second rectangle vanishes.)

$$\begin{aligned}
 \text{(b)} \quad \int_0^2 (x^2 - x) dx &= \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x \quad [\Delta x = 2/n \text{ and } x_i = 2i/n] \\
 &= \lim_{n \rightarrow \infty} \sum_{i=1}^n \left(\frac{4i^2}{n^2} - \frac{2i}{n} \right) \left(\frac{2}{n} \right) = \lim_{n \rightarrow \infty} \frac{2}{n} \left[\frac{4}{n^2} \sum_{i=1}^n i^2 - \frac{2}{n} \sum_{i=1}^n i \right] \\
 &= \lim_{n \rightarrow \infty} \left[\frac{8}{n^3} \cdot \frac{n(n+1)(2n+1)}{6} - \frac{4}{n^2} \cdot \frac{n(n+1)}{2} \right] \\
 &= \lim_{n \rightarrow \infty} \left[\frac{4}{3} \cdot \frac{n+1}{n} \cdot \frac{2n+1}{n} - 2 \cdot \frac{n+1}{n} \right] \\
 &= \lim_{n \rightarrow \infty} \left[\frac{4}{3} \left(1 + \frac{1}{n} \right) \left(2 + \frac{1}{n} \right) - 2 \left(1 + \frac{1}{n} \right) \right] = \frac{4}{3} \cdot 1 \cdot 2 - 2 \cdot 1 = \frac{2}{3}
 \end{aligned}$$

$$\text{(c)} \quad \int_0^2 (x^2 - x) dx = \left[\frac{1}{3}x^3 - \frac{1}{2}x^2 \right]_0^2 = \left(\frac{8}{3} - 2 \right) = \frac{2}{3}$$

(d)

$\int_0^2 (x^2 - x) dx = A_1 - A_2$, where A_1 and A_2 are the areas shown in the diagram.

$$3. \int_0^1 (x + \sqrt{1-x^2}) dx = \int_0^1 x dx + \int_0^1 \sqrt{1-x^2} dx = I_1 + I_2.$$

I_1 can be interpreted as the area of the triangle shown in the figure and I_2 can be interpreted as the area of the quarter-circle. Area $= \frac{1}{2}(1)(1) + \frac{1}{4}(\pi)(1)^2 = \frac{1}{2} + \frac{\pi}{4}$.

$$4. \text{ On } [0, \pi], \lim_{n \rightarrow \infty} \sum_{i=1}^n \sin x_i \Delta x = \int_0^\pi \sin x dx = [-\cos x]_0^\pi = -(-1) - (-1) = 2.$$

$$5. \int_0^6 f(x) dx = \int_0^4 f(x) dx + \int_4^6 f(x) dx \Rightarrow 10 = 7 + \int_4^6 f(x) dx \Rightarrow \int_4^6 f(x) dx = 10 - 7 = 3$$

$$6. (a) \int_1^5 (x + 2x^5) dx = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i) \Delta x \quad \left[\Delta x = \frac{5-1}{n} = \frac{4}{n}, x_i = 1 + \frac{4i}{n} \right]$$

$$= \lim_{n \rightarrow \infty} \sum_{i=1}^n \left[\left(1 + \frac{4i}{n} \right) + 2 \left(1 + \frac{4i}{n} \right)^5 \right] \cdot \frac{4}{n}$$

$$= \lim_{n \rightarrow \infty} \frac{1305n^4 + 3126n^3 + 2080n^2 - 256}{n^3} \cdot \frac{4}{n} = 5220$$

$$(b) \int_1^5 (x + 2x^5) dx = \left[\frac{1}{2}x^2 + \frac{2}{6}x^6 \right]_1^5 = \left(\frac{25}{2} + \frac{15,625}{3} \right) - \left(\frac{1}{2} + \frac{1}{3} \right) = 12 + 5208 = 5220$$

7. First note that either a or b must be the graph of $\int_0^x f(t) dt$, since $\int_0^0 f(t) dt = 0$, and $c(0) \neq 0$. Now notice that $b > 0$ when c is increasing, and that $c > 0$ when a is increasing. It follows that c is the graph of $f(x)$, b is the graph of $f'(x)$, and a is the graph of $\int_0^x f(t) dt$.

$$8. (a) \text{ By FTC2, we have } \int_0^{\pi/2} \frac{d}{dx} \left(\sin \frac{x}{2} \cos \frac{x}{3} \right) dx = \left[\sin \frac{x}{2} \cos \frac{x}{3} \right]_0^{\pi/2} = \frac{1}{\sqrt{2}} \cdot \frac{\sqrt{3}}{2} - 0 \cdot 1 = \frac{\sqrt{6}}{4}.$$

$$(b) \frac{d}{dx} \int_0^{\pi/2} \sin \frac{x}{2} \cos \frac{x}{3} dx = 0, \text{ since the definite integral is a constant.}$$

$$(c) \frac{d}{dx} \int_x^{\pi/2} \sin \frac{t}{2} \cos \frac{t}{3} dt = \frac{d}{dx} \left(- \int_{\pi/2}^x \sin \frac{t}{2} \cos \frac{t}{3} dt \right) = - \frac{d}{dx} \int_{\pi/2}^x \sin \frac{t}{2} \cos \frac{t}{3} dt = - \sin \frac{x}{2} \cos \frac{x}{3},$$

by FTC1.

$$9. \int_1^2 (8x^3 + 3x^2) dx = \left[8 \cdot \frac{1}{4} x^4 + 3 \cdot \frac{1}{3} x^3 \right]_1^2 = [2x^4 + x^3]_1^2 = (2 \cdot 2^4 + 2^3) - (2 + 1) = 40 - 3 = 37$$

$$10. \int_0^T (x^4 - 8x + 7) dx = \left[\frac{1}{5} x^5 - 4x^2 + 7x \right]_0^T = \left(\frac{1}{5} T^5 - 4T^2 + 7T \right) - 0 = \frac{1}{5} T^5 - 4T^2 + 7T$$

$$11. \int_0^1 (1 - x^9) dx = \left[x - \frac{1}{10} x^{10} \right]_0^1 = \left(1 - \frac{1}{10} \right) - 0 = \frac{9}{10}$$

12. Let $u = 1 - x$, so $du = -dx$ and $dx = -du$. When $x = 0$, $u = 1$; when $x = 1$, $u = 0$. Thus,

$$\int_0^1 (1 - x)^9 dx = \int_1^0 u^9 (-du) = \int_0^1 u^9 du = \frac{1}{10} [u^{10}]_0^1 = \frac{1}{10} (1 - 0) = \frac{1}{10}.$$

$$13. \int_1^9 \frac{\sqrt{u} - 2u^2}{u} du = \int_1^9 (u^{-1/2} - 2u) du = \left[2u^{1/2} - u^2 \right]_1^9 = (6 - 81) - (2 - 1) = -76$$

$$14. \int_0^1 (\sqrt[4]{u} + 1)^2 du = \int_0^1 (u^{1/2} + 2u^{1/4} + 1) du = \left[\frac{2}{3} u^{3/2} + \frac{8}{5} u^{5/4} + u \right]_0^1 = \left(\frac{2}{3} + \frac{8}{5} + 1 \right) - 0 = \frac{49}{15}$$

15. Let $u = y^2 + 1$, so $du = 2y dy$ and $y dy = \frac{1}{2} du$. When $y = 0$, $u = 1$; when $y = 1$, $u = 2$. Thus,

$$\int_0^1 y(y^2 + 1)^5 dy = \int_1^2 u^5 \left(\frac{1}{2} du \right) = \frac{1}{2} \left[\frac{1}{6} u^6 \right]_1^2 = \frac{1}{12} (64 - 1) = \frac{63}{12} = \frac{21}{4}.$$

16. Let $u = 1 + y^3$, so $du = 3y^2 dy$ and $y^2 dy = \frac{1}{3} du$. When $y = 0$, $u = 1$; when $y = 2$, $u = 9$. Thus,

$$\int_0^2 y^2 \sqrt{1 + y^3} dy = \int_1^9 u^{1/2} \left(\frac{1}{3} du \right) = \frac{1}{3} \left[\frac{2}{3} u^{3/2} \right]_1^9 = \frac{2}{9} (27 - 1) = \frac{52}{9}.$$

17. $\int_1^5 \frac{dt}{(t-4)^2}$ does not exist because the function $f(t) = \frac{1}{(t-4)^2}$ has an infinite discontinuity at $t = 4$; that is, f is discontinuous on the interval $[1, 5]$.

18. Let $u = 3\pi t$, so $du = 3\pi dt$. When $t = 0$, $u = 0$; when $t = 1$, $u = 3\pi$. Thus,

$$\int_0^1 \sin(3\pi t) dt = \int_0^{3\pi} \sin u \left(\frac{1}{3\pi} du \right) = \frac{1}{3\pi} [-\cos u]_0^{3\pi} = -\frac{1}{3\pi} (-1 - 1) = \frac{2}{3\pi}.$$

19. Let $u = v^3$, so $du = 3v^2 dv$. When $v = 0$, $u = 0$; when $v = 1$, $u = 1$. Thus,

$$\int_0^1 v^2 \cos(v^3) dv = \int_0^1 \cos u \left(\frac{1}{3} du \right) = \frac{1}{3} [\sin u]_0^1 = \frac{1}{3} (\sin 1 - 0) = \frac{1}{3} \sin 1.$$

20. $\int_{-1}^1 \frac{\sin x}{1 + x^2} dx = 0$ by Theorem 5.5.6(b), since $f(x) = \frac{\sin x}{1 + x^2}$ is an odd function.

21. Let $u = x^2 + 4x$. Then $du = (2x + 4) dx = 2(x + 2) dx$, so

$$\int \frac{x + 2}{\sqrt{x^2 + 4x}} dx = \int u^{-1/2} \left(\frac{1}{2} du \right) = \frac{1}{2} \cdot 2u^{1/2} + C = \sqrt{u} + C = \sqrt{x^2 + 4x} + C.$$

22. Let $u = 3t$. Then $du = 3 dt$, so $\int \csc^2 3t dt = \int \csc^2 u \left(\frac{1}{3} du \right) = \frac{1}{3} (-\cot u) + C = -\frac{1}{3} \cot 3t + C$.

23. Let $u = \sin \pi t$. Then $du = \pi \cos \pi t dt$, so $\int \sin \pi t \cos \pi t dt = \int u \left(\frac{1}{\pi} du \right) = \frac{1}{\pi} \cdot \frac{1}{2} u^2 + C = \frac{1}{2\pi} (\sin \pi t)^2 + C$.

24. Let $u = \cos x$. Then $du = -\sin x dx$, so

$$\int \sin x \cos(\cos x) dx = -\int \cos u du = -\sin u + C = -\sin(\cos x) + C.$$

25. Let $u = 2\theta$. Then $du = 2 d\theta$, so

$$\begin{aligned} \int_0^{\pi/8} \sec 2\theta \tan 2\theta d\theta &= \int_0^{\pi/4} \sec u \tan u \left(\frac{1}{2} du \right) = \frac{1}{2} [\sec u]_0^{\pi/4} = \frac{1}{2} (\sec \frac{\pi}{4} - \sec 0) \\ &= \frac{1}{2} (\sqrt{2} - 1) = \frac{1}{2} \sqrt{2} - \frac{1}{2} \end{aligned}$$

26. Let $u = 1 + \tan t$, so $du = \sec^2 t \, dt$. When $t = 0$, $u = 1$; when $t = \frac{\pi}{4}$, $u = 2$. Thus,

$$\int_0^{\pi/4} (1 + \tan t)^3 \sec^2 t \, dt = \int_1^2 u^3 \, du = \left[\frac{1}{4} u^4 \right]_1^2 = \frac{1}{4} (2^4 - 1^4) = \frac{1}{4} (16 - 1) = \frac{15}{4}.$$

27. Since $x^2 - 4 < 0$ for $0 \leq x < 2$ and $x^2 - 4 > 0$ for $2 < x \leq 3$, we have $|x^2 - 4| = -(x^2 - 4) = 4 - x^2$ for $0 \leq x < 2$ and $|x^2 - 4| = x^2 - 4$ for $2 < x \leq 3$. Thus,

$$\begin{aligned} \int_0^3 |x^2 - 4| \, dx &= \int_0^2 (4 - x^2) \, dx + \int_2^3 (x^2 - 4) \, dx = \left[4x - \frac{x^3}{3} \right]_0^2 + \left[\frac{x^3}{3} - 4x \right]_2^3 \\ &= \left(8 - \frac{8}{3} \right) - 0 + (9 - 12) - \left(\frac{8}{3} - 8 \right) = \frac{16}{3} - 3 + \frac{16}{3} = \frac{32}{3} - 3 = \frac{23}{3} \end{aligned}$$

28. Since $\sqrt{x} - 1 < 0$ for $0 \leq x < 1$ and $\sqrt{x} - 1 > 0$ for $1 < x \leq 4$, we have $|\sqrt{x} - 1| = -(\sqrt{x} - 1) = 1 - \sqrt{x}$ for $0 \leq x < 1$ and $|\sqrt{x} - 1| = \sqrt{x} - 1$ for $1 < x \leq 4$. Thus,

$$\begin{aligned} \int_0^4 |\sqrt{x} - 1| \, dx &= \int_0^1 (1 - \sqrt{x}) \, dx + \int_1^4 (\sqrt{x} - 1) \, dx = \left[x - \frac{2}{3} x^{3/2} \right]_0^1 + \left[\frac{2}{3} x^{3/2} - x \right]_1^4 \\ &= \left(1 - \frac{2}{3} \right) - 0 + \left(\frac{16}{3} - 4 \right) - \left(\frac{2}{3} - 1 \right) = \frac{1}{3} + \frac{16}{3} - 4 + \frac{1}{3} = 6 - 4 = 2 \end{aligned}$$

In Exercises 29 and 30, let $f(x)$ denote the integrand and $F(x)$ its antiderivative (with $C = 0$).

29. Let $u = 1 + \sin x$. Then $du = \cos x \, dx$, so

$$\int \frac{\cos x \, dx}{\sqrt{1 + \sin x}} = \int u^{-1/2} \, du = 2u^{1/2} + C = 2\sqrt{1 + \sin x} + C.$$

30. Let $u = x^2 + 1$. Then $x^2 = u - 1$ and $x \, dx = \frac{1}{2} \, du$, so

$$\begin{aligned} \int \frac{x^3}{\sqrt{x^2 + 1}} \, dx &= \int \frac{(u - 1)}{\sqrt{u}} \left(\frac{1}{2} \, du \right) = \frac{1}{2} \int (u^{1/2} - u^{-1/2}) \, du \\ &= \frac{1}{2} \left(\frac{2}{3} u^{3/2} - 2u^{1/2} \right) + C \\ &= \frac{1}{3} (x^2 + 1)^{3/2} - (x^2 + 1)^{1/2} + C \\ &= \frac{1}{3} (x^2 + 1)^{1/2} [(x^2 + 1) - 3] + C \\ &= \frac{1}{3} \sqrt{x^2 + 1} (x^2 - 2) + C \end{aligned}$$

31. From the graph, it appears that the area under the curve $y = x\sqrt{x}$ between $x = 0$ and $x = 4$ is somewhat less than half the area of an 8×4 rectangle, so perhaps about 13 or 14. To find the exact value, we evaluate

$$\int_0^4 x \sqrt{x} \, dx = \int_0^4 x^{3/2} \, dx = \left[\frac{2}{5} x^{5/2} \right]_0^4 = \frac{2}{5} (4)^{5/2} = \frac{64}{5} = 12.8.$$

32. From the graph, it seems as though $\int_0^{2\pi} \cos^2 x \sin^3 x \, dx$ is equal to 0.

To evaluate the integral, we write the integral as

$$I = \int_0^{2\pi} \cos^2 x (1 - \cos^2 x) \sin x \, dx \text{ and let } u = \cos x \Rightarrow$$

$$du = -\sin x \, dx. \text{ Thus, } I = \int_1^{-1} u^2(1 - u^2)(-du) = 0.$$

33. By FTC1, $F(x) = \int_1^x \sqrt{1+t^4} \, dt \Rightarrow F'(x) = \sqrt{1+x^4}$.

34. $F(x) = \int_{\pi}^x \tan(s^2) \, ds \Rightarrow F'(x) = \tan(x^2)$

35. $g(x) = \int_0^{x^3} \frac{t \, dt}{\sqrt{1+t^3}}$. Let $y = g(u)$ and $u = x^3$.

$$\text{Then } g'(x) = \frac{dy}{dx} = \frac{dy}{du} \frac{du}{dx} = \frac{u}{\sqrt{1+u^3}} 3x^2 = \frac{x^3}{\sqrt{1+x^9}} 3x^2 = \frac{3x^5}{\sqrt{1+x^9}}.$$

36. Let $u = \cos x$. Then $\frac{du}{dx} = -\sin x$. Also, $\frac{dg}{dx} = \frac{dg}{du} \frac{du}{dx}$, so

$$\begin{aligned} \frac{d}{dx} \int_1^{\cos x} \sqrt[3]{1-t^2} \, dt &= \frac{d}{du} \int_1^u \sqrt[3]{1-t^2} \, dt \cdot \frac{du}{dx} = \sqrt[3]{1-u^2} (-\sin x) \\ &= \sqrt[3]{1-\cos^2 x} (-\sin x) = -\sin x \sqrt[3]{\sin^2 x} = -(\sin x)^{5/3} \end{aligned}$$

37. $y = \int_{\sqrt{x}}^x \frac{\cos \theta}{\theta} \, d\theta = \int_1^x \frac{\cos \theta}{\theta} \, d\theta + \int_{\sqrt{x}}^1 \frac{\cos \theta}{\theta} \, d\theta = \int_1^x \frac{\cos \theta}{\theta} \, d\theta - \int_1^{\sqrt{x}} \frac{\cos \theta}{\theta} \, d\theta \Rightarrow$

$$y' = \frac{\cos x}{x} - \frac{\cos \sqrt{x}}{\sqrt{x}} \cdot \frac{1}{2\sqrt{x}} = \frac{2 \cos x - \cos \sqrt{x}}{2x}$$

38. $y = \int_{2x}^{3x+1} \sin(t^4) \, dt = \int_{2x}^0 \sin(t^4) \, dt + \int_0^{3x+1} \sin(t^4) \, dt = \int_0^{3x+1} \sin(t^4) \, dt - \int_0^{2x} \sin(t^4) \, dt \Rightarrow$

$$y' = \sin[(3x+1)^4] \cdot \frac{d}{dx}(3x+1) - \sin[(2x)^4] \cdot \frac{d}{dx}(2x) = 3 \sin[(3x+1)^4] - 2 \sin[(2x)^4]$$

39. If $1 \leq x \leq 3$, then $\sqrt{1^2+3} \leq \sqrt{x^2+3} \leq \sqrt{3^2+3} \Rightarrow 2 \leq \sqrt{x^2+3} \leq 2\sqrt{3}$, so

$$2(3-1) \leq \int_1^3 \sqrt{x^2+3} \, dx \leq 2\sqrt{3}(3-1); \text{ that is, } 4 \leq \int_1^3 \sqrt{x^2+3} \, dx \leq 4\sqrt{3}.$$

40. If $3 \leq x \leq 5$, then $4 \leq x+1 \leq 6$ and $\frac{1}{6} \leq \frac{1}{x+1} \leq \frac{1}{4}$, so $\frac{1}{6}(5-3) \leq \int_3^5 \frac{1}{x+1} \, dx \leq \frac{1}{4}(5-3)$; that is,

$$\frac{1}{3} \leq \int_3^5 \frac{1}{x+1} \, dx \leq \frac{1}{2}.$$

41. $0 \leq x \leq 1 \Rightarrow 0 \leq \cos x \leq 1 \Rightarrow x^2 \cos x \leq x^2 \Rightarrow$

$$\int_0^1 x^2 \cos x \, dx \leq \int_0^1 x^2 \, dx = \frac{1}{3} [x^3]_0^1 = \frac{1}{3} \text{ [Property 7].}$$

42. On the interval $\left[\frac{\pi}{4}, \frac{\pi}{2}\right]$, x is increasing and $\sin x$ is decreasing, so $\frac{\sin x}{x}$ is decreasing. Therefore, the largest value

of $\frac{\sin x}{x}$ on $\left[\frac{\pi}{4}, \frac{\pi}{2}\right]$ is $\frac{\sin(\pi/4)}{\pi/4} = \frac{\sqrt{2}/2}{\pi/4} = \frac{2\sqrt{2}}{\pi}$. By Property 8 with $M = \frac{2\sqrt{2}}{\pi}$ we get

$$\int_{\pi/4}^{\pi/2} \frac{\sin x}{x} \, dx \leq \frac{2\sqrt{2}}{\pi} \left(\frac{\pi}{2} - \frac{\pi}{4}\right) = \frac{\sqrt{2}}{2}.$$

43. Let $f(x) = \sqrt{1+x^3}$ on $[0, 1]$. The Midpoint Rule with $n = 5$ gives

$$\begin{aligned}\int_0^1 \sqrt{1+x^3} dx &\approx \frac{1}{5}[f(0.1) + f(0.3) + f(0.5) + f(0.7) + f(0.9)] \\ &= \frac{1}{5}[\sqrt{1+(0.1)^3} + \sqrt{1+(0.3)^3} + \cdots + \sqrt{1+(0.9)^3}] \approx 1.110\end{aligned}$$

44. (a) displacement $= \int_0^5 (t^2 - t) dt = [\frac{1}{3}t^3 - \frac{1}{2}t^2]_0^5 = \frac{125}{3} - \frac{25}{2} = \frac{175}{6} = 29.1\bar{6}$ meters

$$\begin{aligned}\text{(b) distance traveled} &= \int_0^5 |t^2 - t| dt = \int_0^1 |t(t-1)| dt + \int_1^5 (t^2 - t) dt \\ &= [\frac{1}{2}t^2 - \frac{1}{3}t^3]_0^1 + [\frac{1}{3}t^3 - \frac{1}{2}t^2]_1^5 \\ &= \frac{1}{2} - \frac{1}{3} - 0 + (\frac{125}{3} - \frac{25}{2}) - (\frac{1}{3} - \frac{1}{2}) = \frac{177}{6} = 29.5 \text{ meters}\end{aligned}$$

45. Note that $r(t) = b'(t)$, where $b(t)$ = the number of barrels of oil consumed up to time t . So, by the Net Change Theorem, $\int_0^3 r(t) dt = b(3) - b(0)$ represents the number of barrels of oil consumed from Jan. 1, 2000, through Jan. 1, 2003.

46. Distance covered $= \int_0^{5.0} v(t) dt \approx M_5 = \frac{5.0-0}{5}[v(0.5) + v(1.5) + v(2.5) + v(3.5) + v(4.5)]$
 $= 1(4.67 + 8.86 + 10.22 + 10.67 + 10.81) = 45.23$ m

47. We use the Midpoint Rule with $n = 6$ and $\Delta t = \frac{24-0}{6} = 4$. The increase in the bee population was

$$\begin{aligned}\int_0^{24} r(t) dt &\approx M_6 = 4[r(2) + r(6) + r(10) + r(14) + r(18) + r(22)] \\ &\approx 4[50 + 1000 + 7000 + 8550 + 1350 + 150] \\ &= 4(18,100) = 72,400\end{aligned}$$

48. $A_1 = \frac{1}{2}bh = \frac{1}{2}(2)(2) = 2$, $A_2 = \frac{1}{2}bh = \frac{1}{2}(1)(1) = \frac{1}{2}$, and since $y = -\sqrt{1-x^2}$ for $0 \leq x \leq 1$ represents a quarter-circle with radius 1, $A_3 = \frac{1}{4}\pi r^2 = \frac{1}{4}\pi(1)^2 = \frac{\pi}{4}$. So
 $\int_{-3}^1 f(x) dx = A_1 - A_2 - A_3 = 2 - \frac{1}{2} - \frac{\pi}{4} = \frac{1}{4}(6 - \pi)$.

49. By the Fundamental Theorem of Calculus, we know that $F(x) = \int_a^x t^2 \sin(t^2) dt$ is an antiderivative of $f(x) = x^2 \sin(x^2)$. This integral cannot be expressed in any simpler form. Since $\int_a^a f dt = 0$ for any a , we can take $a = 1$, and then $F(1) = 0$, as required. So $F(x) = \int_1^x t^2 \sin(t^2) dt$ is the desired function.

50. (a) C is increasing on those intervals where C' is positive. By the Fundamental Theorem of Calculus,

$$\begin{aligned}C'(x) &= \frac{d}{dx} \left[\int_0^x \cos\left(\frac{\pi}{2}t^2\right) dt \right] = \cos\left(\frac{\pi}{2}x^2\right). \text{ This is positive when } \frac{\pi}{2}x^2 \text{ is in the interval} \\ &((2n - \frac{1}{2})\pi, (2n + \frac{1}{2})\pi), n \text{ any integer. This implies that } (2n - \frac{1}{2})\pi < \frac{\pi}{2}x^2 < (2n + \frac{1}{2})\pi \Leftrightarrow \\ &0 \leq |x| \leq 1 \text{ or } \sqrt{4n-1} < |x| < \sqrt{4n+1}, n \text{ any positive integer. So } C \text{ is increasing on the intervals } [-1, 1], \\ &[\sqrt{3}, \sqrt{5}], [-\sqrt{5}, -\sqrt{3}], [\sqrt{7}, 3], [-3, -\sqrt{7}], \dots\end{aligned}$$

- (b) C is concave upward on those intervals where $C'' > 0$. We differentiate C' to find C'' : $C'(x) = \cos(\frac{\pi}{2}x^2)$
 $\Rightarrow C''(x) = -\sin(\frac{\pi}{2}x^2)(\frac{\pi}{2} \cdot 2x) = -\pi x \sin(\frac{\pi}{2}x^2)$. For $x > 0$, this is positive where

$(2n-1)\pi < \frac{\pi}{2}x^2 < 2n\pi$, n any positive integer $\Leftrightarrow \sqrt{2(2n-1)} < x < 2\sqrt{n}$, n any positive integer.

Since there is a factor of $-x$ in C'' , the intervals of upward concavity for $x < 0$ are $(-\sqrt{2(2n+1)}, -2\sqrt{n})$,

n any nonnegative integer. That is, C is concave upward on $(-\sqrt{2}, 0)$, $(\sqrt{2}, 2)$, $(-\sqrt{6}, -2)$, $(\sqrt{6}, 2\sqrt{2})$, $\dots$

(c)

From the graphs, we can determine that $\int_0^x \cos(\frac{\pi}{2}t^2) dt = 0.7$ at $x \approx 0.76$ and $x \approx 1.22$.

(d)

The graphs of $S(x)$ and $C(x)$ have similar shapes, except that S 's flattens out near the origin, while C 's does not. Note that for $x > 0$, C is increasing where S is concave up, and C is decreasing where S is concave down. Similarly, S is increasing where C is concave down, and S is decreasing where C is concave up. For $x < 0$, these relationships are reversed; that is, C is increasing where S is concave down, and S is increasing where C is concave up. See Example 5.3.3 and Exercise 5.3.49 for a discussion of $S(x)$.

$$51. \int_0^x f(t) dt = x \sin x + \int_0^x \frac{f(t)}{1+t^2} dt \Rightarrow f(x) = x \cos x + \sin x + \frac{f(x)}{1+x^2} \text{ (by differentiation)} \Rightarrow$$

$$f(x) \left(1 - \frac{1}{1+x^2} \right) = x \cos x + \sin x \Rightarrow f(x) \left(\frac{x^2}{1+x^2} \right) = x \cos x + \sin x \Rightarrow$$

$$f(x) = \frac{1+x^2}{x^2} (x \cos x + \sin x)$$

52. From the given equation, $\int_a^x f(t) dt = \sin x - \frac{1}{2}$. Differentiating both sides using FTC1 gives $f(x) = \cos x$. We put $x = a$ into the first equation to get $0 = \sin a - \frac{1}{2}$, so $a = \frac{\pi}{6}$ satisfies the given equation.

53. Let $u = f(x)$ and $du = f'(x) dx$. So $2 \int_a^b f(x) f'(x) dx = 2 \int_{f(a)}^{f(b)} u du = [u^2]_{f(a)}^{f(b)} = [f(b)]^2 - [f(a)]^2$.

54. Let $F(x) = \int_2^x \sqrt{1+t^3} dt$. Then $F'(2) = \lim_{h \rightarrow 0} \frac{F(2+h) - F(2)}{h} = \lim_{h \rightarrow 0} \frac{1}{h} \int_2^{2+h} \sqrt{1+t^3} dt$, and

$$F'(x) = \sqrt{1+x^3}, \text{ so } \lim_{h \rightarrow 0} \frac{1}{h} \int_2^{2+h} \sqrt{1+t^3} dt = F'(2) = \sqrt{1+2^3} = \sqrt{9} = 3.$$

55. Let $u = 1 - x$. Then $du = -dx$, so $\int_0^1 f(1-x) dx = \int_1^0 f(u)(-du) = \int_0^1 f(u) du = \int_0^1 f(x) dx$.

$$56. \lim_{n \rightarrow \infty} \frac{1}{n} \left[\left(\frac{1}{n} \right)^9 + \left(\frac{2}{n} \right)^9 + \left(\frac{3}{n} \right)^9 + \cdots + \left(\frac{n}{n} \right)^9 \right] = \lim_{n \rightarrow \infty} \frac{1-0}{n} \sum_{i=1}^n \left(\frac{i}{n} \right)^9 = \int_0^1 x^9 dx = \left[\frac{x^{10}}{10} \right]_0^1 = \frac{1}{10}$$

The limit is based on Riemann sums using right endpoints and subintervals of equal length.

□ PROBLEMS PLUS

1. Differentiating both sides of the equation $x \sin \pi x = \int_0^{x^2} f(t) dt$ (using FTC1 and the Chain Rule for the right side) gives $\sin \pi x + \pi x \cos \pi x = 2xf(x^2)$. Letting $x = 2$ so that $f(x^2) = f(4)$, we obtain $\sin 2\pi + 2\pi \cos 2\pi = 4f(4)$, so $f(4) = \frac{1}{4}(0 + 2\pi \cdot 1) = \frac{\pi}{2}$.

2. (a) Let $f(x) = ax^2 + bx + c$. $f(0) = f(\pi) = 0$, so we know that $f(0) = 0 \Rightarrow c = 0$, and $f(\pi) = 0 \Leftrightarrow a\pi^2 + b\pi = 0 \Leftrightarrow b = -a\pi$. So $f(x) = ax^2 - a\pi x$. Now we want the maximum value of $f(x)$ on $[0, \pi]$ to be the same as that of $\sin x$, that is, 1. So we find the value of x at which f has a maximum by differentiating and setting $f'(x) = 0 \Leftrightarrow 2ax - a\pi = 0 \Leftrightarrow x = \frac{\pi}{2}$. Now $f(\frac{\pi}{2}) = a(\frac{\pi}{2})^2 - a\pi(\frac{\pi}{2}) = -\frac{1}{4}\pi^2 a$. We set this equal to 1, in order to find a : $-\frac{1}{4}\pi^2 a = 1 \Leftrightarrow a = -\frac{4}{\pi^2} \Rightarrow b = -a\pi = \frac{4}{\pi}$. Thus, the desired function is $f(x) = -\frac{4}{\pi^2}x^2 + \frac{4}{\pi}x$.

Alternate solution (without calculus): Use $f(x) = ax(x - \pi)$.

- (b) Once again, $g(0) = g(\pi) = 0 \Rightarrow g(x) = ax^2 - a\pi x$. We want $g'(0) = [\frac{d}{dx}(\sin x)]_0 = \cos 0 = 1$. We calculated $g'(x)$ in part (a), so we set $g'(0) = 1 \Leftrightarrow 2a(0) - a\pi = 1 \Leftrightarrow a = -\frac{1}{\pi}$. We also want $g'(\pi) = [\frac{d}{dx}(\sin x)]_\pi = \cos \pi = -1$, so we check that $g'(\pi) = -1$ with $a = -\frac{1}{\pi}$: $g'(\pi) = 2(-\frac{1}{\pi})\pi - (-\frac{1}{\pi})\pi = -1$. Thus, the desired function is $g(x) = -\frac{1}{\pi}x^2 + x$.

- (c) Again, $h(x) = ax^2 - a\pi x$. Now we want the area under the curves of $h(x)$ and $\sin x$ to be the same; that is, $\int_0^\pi h(x) dx = \int_0^\pi \sin x dx = [-\cos x]_0^\pi = (1) - (-1) = 2$. We integrate h between 0 and π and set the result equal to 2: $\int_0^\pi (ax^2 - a\pi x) dx = [\frac{1}{3}ax^3 - \frac{1}{2}a\pi x^2]_0^\pi = \frac{1}{3}a\pi^3 - \frac{1}{2}a\pi^3 = -\frac{1}{6}a\pi^3 = 2 \Leftrightarrow a = -12/\pi^3$. Thus, the desired function is $h(x) = -\frac{12}{\pi^3}x^2 + \frac{12}{\pi^2}x$.

(d)

3. For $1 \leq x \leq 2$, we have $x^4 \leq 2^4 = 16$, so $1 + x^4 \leq 17$ and $\frac{1}{1+x^4} \geq \frac{1}{17}$. Thus,

$$\int_1^2 \frac{1}{1+x^4} dx \geq \int_1^2 \frac{1}{17} dx = \frac{1}{17}. \text{ Also } 1 + x^4 > x^4 \text{ for } 1 \leq x \leq 2, \text{ so } \frac{1}{1+x^4} < \frac{1}{x^4} \text{ and}$$

$$\int_1^2 \frac{1}{1+x^4} dx < \int_1^2 x^{-4} dx = \left[\frac{x^{-3}}{-3} \right]_1^2 = -\frac{1}{24} + \frac{1}{3} = \frac{7}{24}. \text{ Thus, we have the estimate}$$

$$\frac{1}{17} \leq \int_1^2 \frac{1}{1+x^4} dx \leq \frac{7}{24}.$$

4. By FTC2, $\int_0^1 f'(x) dx = f(1) - f(0) = 1 - 0 = 1$.

5. Such a function cannot exist. $f'(x) > 3$ for all x means that f is differentiable (and hence continuous) for all x . So by FTC2, $\int_1^4 f'(x) dx = f(4) - f(1) = 7 - (-1) = 8$. However, if $f'(x) > 3$ for all x , then $\int_1^4 f'(x) dx \geq 3 \cdot (4 - 1) = 9$ by Comparison Property 8 in Section 5.2.

Another solution: By the Mean Value Theorem, there exists a number $c \in (1, 4)$ such that

$$f'(c) = \frac{f(4) - f(1)}{4 - 1} = \frac{7 - (-1)}{3} = \frac{8}{3} \Rightarrow 8 = 3f'(c). \text{ But } f'(x) > 3 \Rightarrow 3f'(c) > 9, \text{ so such a function cannot exist.}$$

6. (a)

From the graph of $f(x) = \frac{2cx - x^2}{c^3}$, it appears that the areas are equal; that is, the area enclosed is independent of c .

- (b) We first find the x -intercepts of the curve, to determine the limits of integration: $y = 0 \Leftrightarrow 2cx - x^2 = 0 \Leftrightarrow x = 0$ or $x = 2c$. Now we integrate the function between these limits to find the enclosed area:

$$A = \int_0^{2c} \frac{2cx - x^2}{c^3} dx = \frac{1}{c^3} \left[cx^2 - \frac{1}{3}x^3 \right]_0^{2c} = \frac{1}{c^3} \left[c(2c)^2 - \frac{1}{3}(2c)^3 \right] = \frac{1}{c^3} \left[4c^3 - \frac{8}{3}c^3 \right] = \frac{4}{3}, \text{ a constant.}$$

(c)

The vertices of the family of parabolas seem to determine a branch of a hyperbola.

- (d) For a particular c , the vertex is the point where the maximum occurs. We have seen that the x -intercepts are 0 and $2c$, so by symmetry, the maximum occurs at $x = c$, and its value is $\frac{2c(c) - c^2}{c^3} = \frac{1}{c}$. So we are interested in the curve consisting of all points of the form $\left(c, \frac{1}{c}\right)$, $c > 0$. This is the part of the hyperbola $y = 1/x$ lying in the first quadrant.

7. $f(x) = \int_0^{g(x)} \frac{1}{\sqrt{1+t^3}} dt$, where $g(x) = \int_0^{\cos x} [1 + \sin(t^2)] dt$. Using FTC1 and the Chain Rule (twice) we have $f'(x) = \frac{1}{\sqrt{1+[g(x)]^3}} g'(x) = \frac{1}{\sqrt{1+[g(x)]^3}} [1 + \sin(\cos^2 x)] (-\sin x)$. Now $g\left(\frac{\pi}{2}\right) = \int_0^0 [1 + \sin(t^2)] dt = 0$, so $f'\left(\frac{\pi}{2}\right) = \frac{1}{\sqrt{1+0}} (1 + \sin 0)(-1) = 1 \cdot 1 \cdot (-1) = -1$.
8. If $f(x) = \int_0^x x^2 \sin(t^2) dt = x^2 \int_0^x \sin(t^2) dt$, then $f'(x) = x^2 \sin(x^2) + 2x \int_0^x \sin(t^2) dt$, by the Product Rule and FTC1.

9. $f(x) = 2 + x - x^2 = (-x + 2)(x + 1) = 0 \Leftrightarrow x = 2$ or $x = -1$. $f(x) \geq 0$ for $x \in [-1, 2]$ and $f(x) < 0$ everywhere else. The integral $\int_a^b (2 + x - x^2) dx$ has a maximum on the interval where the integrand is positive, which is $[-1, 2]$. So $a = -1$, $b = 2$. (Any larger interval gives a smaller integral since $f(x) < 0$ outside $[-1, 2]$. Any smaller interval also gives a smaller integral since $f(x) \geq 0$ in $[-1, 2]$.)

10. This sum can be interpreted as a Riemann sum, with the right endpoints of the subintervals as sample points and with $a = 0$, $b = 10,000$, and $f(x) = \sqrt{x}$. So we approximate

$$\sum_{i=1}^{10,000} \sqrt{i} \approx \lim_{n \rightarrow \infty} \frac{10,000}{n} \sum_{i=1}^n \sqrt{\frac{10,000i}{n}} = \int_0^{10,000} \sqrt{x} dx = \left[\frac{2}{3} x^{3/2} \right]_0^{10,000} = \frac{2}{3} (1,000,000) \approx 666,667.$$

Alternate method: We can use graphical methods as follows:

From the figure we see that $\int_{i-1}^i \sqrt{x} dx < \sqrt{i} < \int_i^{i+1} \sqrt{x} dx$, so

$$\int_0^{10,000} \sqrt{x} dx < \sum_{i=1}^{10,000} \sqrt{i} < \int_1^{10,001} \sqrt{x} dx. \text{ Since}$$

$$\int \sqrt{x} dx = \frac{2}{3} x^{3/2} + C, \text{ we get } \int_0^{10,000} \sqrt{x} dx = 666,666.\bar{6} \text{ and}$$

$$\int_1^{10,001} \sqrt{x} dx = \frac{2}{3} \left[(10,001)^{3/2} - 1 \right] \approx 666,766.$$

Hence, $666,666.\bar{6} < \sum_{i=1}^{10,000} \sqrt{i} < 666,766$. We can estimate the sum by averaging these bounds:

$$\sum_{i=1}^{10,000} \sqrt{i} \approx \frac{666,666.\bar{6} + 666,766}{2} \approx 666,716. \text{ The actual value is about } 666,716.46.$$

11. (a) We can split the integral $\int_0^n \lfloor x \rfloor dx$ into the sum $\sum_{i=1}^n \left[\int_{i-1}^i \lfloor x \rfloor dx \right]$. But on each of the intervals $[i-1, i)$ of

integration, $\lfloor x \rfloor$ is a constant function, namely $i-1$. So the i th integral in the sum is equal to

$$(i-1)[i - (i-1)] = (i-1). \text{ So the original integral is equal to } \sum_{i=1}^n (i-1) = \sum_{i=1}^{n-1} i = \frac{(n-1)n}{2}.$$

- (b) We can write $\int_a^b \lfloor x \rfloor dx = \int_0^b \lfloor x \rfloor dx - \int_0^a \lfloor x \rfloor dx$.

Now $\int_0^b \lfloor x \rfloor dx = \int_0^{\lfloor b \rfloor} \lfloor x \rfloor dx + \int_{\lfloor b \rfloor}^b \lfloor x \rfloor dx$. The first of these integrals is equal to $\frac{1}{2}(\lfloor b \rfloor - 1)\lfloor b \rfloor$, by part (a),

and since $\lfloor x \rfloor = \lfloor b \rfloor$ on $[\lfloor b \rfloor, b]$, the second integral is just $\lfloor b \rfloor(b - \lfloor b \rfloor)$. So

$$\int_0^b \lfloor x \rfloor dx = \frac{1}{2}(\lfloor b \rfloor - 1)\lfloor b \rfloor + \lfloor b \rfloor(b - \lfloor b \rfloor) = \frac{1}{2}\lfloor b \rfloor(2b - \lfloor b \rfloor - 1) \text{ and similarly}$$

$$\int_0^a \lfloor x \rfloor dx = \frac{1}{2}\lfloor a \rfloor(2a - \lfloor a \rfloor - 1). \text{ Therefore, } \int_a^b \lfloor x \rfloor dx = \frac{1}{2}\lfloor b \rfloor(2b - \lfloor b \rfloor - 1) - \frac{1}{2}\lfloor a \rfloor(2a - \lfloor a \rfloor - 1).$$

12. By FTC1, $\frac{d}{dx} \int_1^{\sin x} \sqrt{1+u^4} du = \sqrt{1+\sin^4 x}$. Again using FTC1,

$$\frac{d^2}{dx^2} \int_0^x \left(\int_1^{\sin t} \sqrt{1+u^4} du \right) dt = \frac{d}{dx} \int_1^{\sin x} \sqrt{1+u^4} du = \sqrt{1+\sin^4 x} \cos x.$$

13. Differentiating the equation $\int_0^x f(t) dt = [f(x)]^2$ using FTC1 gives $f(x) = 2f(x)f'(x) \Rightarrow$

$f(x)[2f'(x) - 1] = 0$, so $f(x) = 0$ or $f'(x) = \frac{1}{2}$. $f'(x) = \frac{1}{2} \Rightarrow f(x) = \frac{1}{2}x + C$. To find C we substitute into the original equation to get $\int_0^x (\frac{1}{2}t + C) dt = (\frac{1}{2}x + C)^2 \Leftrightarrow \frac{1}{4}x^2 + Cx = \frac{1}{4}x^2 + Cx + C^2$. It follows that $C = 0$, so $f(x) = \frac{1}{2}x$. Therefore, $f(x) = 0$ or $f(x) = \frac{1}{2}x$.

14.

Let x be the distance between the center of the disk and the surface of the liquid.

The wetted circular region has area $\pi r^2 - \pi x^2$ while the unexposed wetted region (shaded in the diagram) has area $2 \int_x^r \sqrt{r^2 - t^2} dt$, so the exposed wetted region has area $A(x) = \pi r^2 - \pi x^2 - 2 \int_x^r \sqrt{r^2 - t^2} dt$, $0 \leq x \leq r$. By FTC1, we have $A'(x) = -2\pi x + 2\sqrt{r^2 - x^2}$.

$$\text{Now } A'(x) > 0 \Rightarrow -2\pi x + 2\sqrt{r^2 - x^2} > 0 \Rightarrow \sqrt{r^2 - x^2} > \pi x \Rightarrow r^2 - x^2 > \pi^2 x^2 \Rightarrow$$

$$r^2 > \pi^2 x^2 + x^2 \Rightarrow r^2 > x^2(\pi^2 + 1) \Rightarrow x^2 < \frac{r^2}{\pi^2 + 1} \Rightarrow x < \frac{r}{\sqrt{\pi^2 + 1}}, \text{ and we'll call this value } x^*.$$

Since $A'(x) > 0$ for $0 < x < x^*$ and $A'(x) < 0$ for $x^* < x < r$, we have an absolute maximum when $x = x^*$.

15. Note that $\frac{d}{dx} \left(\int_0^x \left[\int_0^u f(t) dt \right] du \right) = \int_0^x f(t) dt$ by FTC1, while

$$\begin{aligned} \frac{d}{dx} \left[\int_0^x f(u)(x-u) du \right] &= \frac{d}{dx} \left[x \int_0^x f(u) du \right] - \frac{d}{dx} \left[\int_0^x f(u)u du \right] \\ &= \int_0^x f(u) du + xf(x) - f(x)x = \int_0^x f(u) du \end{aligned}$$

Hence, $\int_0^x f(u)(x-u) du = \int_0^x \left[\int_0^u f(t) dt \right] du + C$. Setting $x = 0$ gives $C = 0$.

16.

We restrict our attention to the triangle shown. A point in this triangle is closer to the side shown than to any other side, so if we find the area of the region R consisting of all points in the triangle that are closer to the center than to that side, we can multiply this area by 4 to find the total area. We find the equation of the set of points which are equidistant from the center and the side: the distance of the point (x, y) from the side is $1 - y$, and its distance from the center is $\sqrt{x^2 + y^2}$.

So the distances are equal if $\sqrt{x^2 + y^2} = 1 - y \Leftrightarrow x^2 + y^2 = 1 - 2y + y^2 \Leftrightarrow y = \frac{1}{2}(1 - x^2)$. Note that the area we are interested in is equal to the area of a triangle plus a crescent-shaped area. To find these areas, we

have to find the y -coordinate h of the horizontal line separating them. From the diagram, $1 - h = \sqrt{2}h \Leftrightarrow$

$h = \frac{1}{1+\sqrt{2}} = \sqrt{2} - 1$. We calculate the areas in terms of h , and substitute afterward.

The area of the triangle is $\frac{1}{2}(2h)(h) = h^2$, and the area of the crescent-shaped section is

$\int_{-h}^h \left[\frac{1}{2}(1-x^2) - h \right] dx = 2 \int_0^h \left(\frac{1}{2} - h - \frac{1}{2}x^2 \right) dx = 2 \left[\left(\frac{1}{2} - h \right)x - \frac{1}{6}x^3 \right]_0^h = h - 2h^2 - \frac{1}{3}h^3$. So the area of

the whole region is

$$\begin{aligned} 4 \left[\left(h - 2h^2 - \frac{1}{3}h^3 \right) + h^2 \right] &= 4h \left(1 - h - \frac{1}{3}h^2 \right) = 4(\sqrt{2} - 1) \left[1 - (\sqrt{2} - 1) - \frac{1}{3}(\sqrt{2} - 1)^2 \right] \\ &= 4(\sqrt{2} - 1) \left(1 - \frac{1}{3}\sqrt{2} \right) = \frac{4}{3}(4\sqrt{2} - 5) \end{aligned}$$

$$\begin{aligned} 17. \lim_{n \rightarrow \infty} \left(\frac{1}{\sqrt{n}\sqrt{n+1}} + \frac{1}{\sqrt{n}\sqrt{n+2}} + \cdots + \frac{1}{\sqrt{n}\sqrt{n+n}} \right) \\ &= \lim_{n \rightarrow \infty} \frac{1}{n} \left(\sqrt{\frac{n}{n+1}} + \sqrt{\frac{n}{n+2}} + \cdots + \sqrt{\frac{n}{n+n}} \right) \\ &= \lim_{n \rightarrow \infty} \frac{1}{n} \left(\frac{1}{\sqrt{1+1/n}} + \frac{1}{\sqrt{1+2/n}} + \cdots + \frac{1}{\sqrt{1+1}} \right) \\ &= \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n f\left(\frac{i}{n}\right) \quad \left[\text{where } f(x) = \frac{1}{\sqrt{1+x}} \right] \\ &= \int_0^1 \frac{1}{\sqrt{1+x}} dx = [2\sqrt{1+x}]_0^1 = 2(\sqrt{2} - 1) \end{aligned}$$

6 □ APPLICATIONS OF INTEGRATION

6.1 Areas between Curves

$$1. A = \int_{x=0}^{x=4} (y_T - y_B) dx = \int_0^4 [(5x - x^2) - x] dx = \int_0^4 (4x - x^2) dx$$

$$= [2x^2 - \frac{1}{3}x^3]_0^4 = (32 - \frac{64}{3}) - (0) = \frac{32}{3}$$

$$2. A = \int_0^6 [2x - (x^2 - 4x)] dx = \int_0^6 (6x - x^2) dx = [3x^2 - \frac{1}{3}x^3]_0^6 = 108 - 72 = 36$$

$$3. A = \int_{y=0}^{y=1} (x_R - x_L) dy = \int_0^1 [\sqrt{y} - (y^2 - 1)] dy = \int_0^1 (y^{1/2} - y^2 + 1) dy$$

$$= [\frac{2}{3}y^{3/2} - \frac{1}{3}y^3 + y]_0^1 = (\frac{2}{3} - \frac{1}{3} + 1) - (0) = \frac{4}{3}$$

$$4. A = \int_0^3 [(2y - y^2) - (y^2 - 4y)] dy = \int_0^3 (-2y^2 + 6y) dy$$

$$= [-\frac{2}{3}y^3 + 3y^2]_0^3 = (-18 + 27) - 0 = 9$$

$$5. A = \int_{-1}^2 [(9 - x^2) - (x + 1)] dx$$

$$= \int_{-1}^2 (8 - x - x^2) dx$$

$$= [8x - \frac{x^2}{2} - \frac{x^3}{3}]_{-1}^2$$

$$= (16 - 2 - \frac{8}{3}) - (-8 - \frac{1}{2} + \frac{1}{3})$$

$$= 22 - 3 + \frac{1}{2} = \frac{39}{2}$$

$$6. A = \int_{\pi/2}^{\pi} (x - \sin x) dx$$

$$= [\frac{x^2}{2} + \cos x]_{\pi/2}^{\pi}$$

$$= (\frac{\pi^2}{2} - 1) - (\frac{\pi^2}{8} + 0)$$

$$= \frac{3\pi^2}{8} - 1$$

7. The curves intersect when $x = x^2 \Rightarrow x^2 - x = 0 \Leftrightarrow x(x - 1) = 0 \Leftrightarrow x = 0, 1$.

$$\begin{aligned} A &= \int_0^1 (x - x^2) dx \\ &= \left[\frac{1}{2}x^2 - \frac{1}{3}x^3 \right]_0^1 \\ &= \frac{1}{2} - \frac{1}{3} \\ &= \frac{1}{6} \end{aligned}$$

$$\begin{aligned} 8. A &= \int_{-1}^1 (x^2 - x^4) dx \\ &= 2 \int_0^1 (x^2 - x^4) dx \\ &= 2 \left[\frac{1}{3}x^3 - \frac{1}{5}x^5 \right]_0^1 \\ &= 2 \left(\frac{1}{3} - \frac{1}{5} \right) = \frac{4}{15} \end{aligned}$$

9. First find the points of intersection: $\sqrt{x+3} = \frac{x+3}{2} \Rightarrow (\sqrt{x+3})^2 = \left(\frac{x+3}{2}\right)^2 \Rightarrow x+3 = \frac{1}{4}(x+3)^2$
 $\Rightarrow 4(x+3) - (x+3)^2 = 0 \Rightarrow (x+3)[4 - (x+3)] = 0 \Rightarrow (x+3)(1-x) = 0 \Rightarrow x = -3 \text{ or } 1$. So

$$A = \int_{-3}^1 \left(\sqrt{x+3} - \frac{x+3}{2} \right) dx = \left[\frac{2}{3}(x+3)^{3/2} - \frac{(x+3)^2}{4} \right]_{-3}^1 = \left(\frac{16}{3} - 4 \right) - (0 - 0) = \frac{4}{3}$$

10. $1 + \sqrt{x} = \frac{3+x}{3} = 1 + \frac{x}{3} \Rightarrow \sqrt{x} = \frac{x}{3} \Rightarrow x = \frac{x^2}{9} \Rightarrow 9x - x^2 = 0 \Rightarrow x(9-x) = 0 \Rightarrow x = 0$
 or 9, so

$$\begin{aligned} A &= \int_0^9 \left[(1 + \sqrt{x}) - \left(\frac{3+x}{3} \right) \right] dx = \int_0^9 \left[(1 + \sqrt{x}) - \left(1 + \frac{x}{3} \right) \right] dx \\ &= \int_0^9 \left(\sqrt{x} - \frac{1}{3}x \right) dx = \left[\frac{2}{3}x^{3/2} - \frac{1}{6}x^2 \right]_0^9 = 18 - \frac{27}{2} = \frac{9}{2} \end{aligned}$$

$$\begin{aligned}
 11. A &= \int_0^1 (\sqrt{x} - x^2) dx \\
 &= \left[\frac{2}{3} x^{3/2} - \frac{1}{3} x^3 \right]_0^1 \\
 &= \frac{2}{3} - \frac{1}{3} \\
 &= \frac{1}{3}
 \end{aligned}$$

$$\begin{aligned}
 12. x = \sqrt[3]{x} &\Rightarrow x^3 = x \Rightarrow x^3 - x = 0 \Rightarrow x(x^2 - 1) = 0 \Rightarrow x(x+1)(x-1) = 0 \Rightarrow \\
 &x = -1, 0, \text{ or } 1, \text{ so}
 \end{aligned}$$

$$\begin{aligned}
 A &= \int_{-1}^1 |\sqrt[3]{x} - x| dx = \int_{-1}^0 (x - \sqrt[3]{x}) dx + \int_0^1 (\sqrt[3]{x} - x) dx = 2 \int_0^1 (x^{1/3} - x) dx \quad [\text{by symmetry}] \\
 &= 2 \left[\frac{3}{4} x^{4/3} - \frac{1}{2} x^2 \right]_0^1 = 2 \left(\frac{3}{4} - \frac{1}{2} \right) = \frac{1}{2}
 \end{aligned}$$

$$13. 12 - x^2 = x^2 - 6 \Leftrightarrow 2x^2 = 18 \Leftrightarrow x^2 = 9 \Leftrightarrow x = \pm 3, \text{ so}$$

$$\begin{aligned}
 A &= \int_{-3}^3 [(12 - x^2) - (x^2 - 6)] dx = 2 \int_0^3 (18 - 2x^2) dx \quad [\text{by symmetry}] \\
 &= 2 \left[18x - \frac{2}{3} x^3 \right]_0^3 = 2[(54 - 18) - 0] = 2(36) = 72
 \end{aligned}$$

14. $x^3 - x = 3x \Rightarrow x^3 - 4x = 0 \Rightarrow x(x^2 - 4) = 0 \Rightarrow x(x+2)(x-2) = 0 \Rightarrow x = 0, -2, \text{ or } 2.$

By symmetry,

$$A = \int_{-2}^2 |3x - (x^3 - x)| dx = 2 \int_0^2 [3x - (x^3 - x)] dx = 2 \int_0^2 (4x - x^3) dx = 2 \left[2x^2 - \frac{1}{4}x^4 \right]_0^2$$

$$= 2(8 - 4) = 8$$

15. $\frac{1}{2}x = \sqrt{x} \Rightarrow \frac{1}{4}x^2 = x \Rightarrow x^2 - 4x = 0 \Rightarrow x(x - 4) = 0 \Rightarrow x = 0 \text{ or } 4, \text{ so}$

$$A = \int_0^4 (\sqrt{x} - \frac{1}{2}x) dx + \int_4^9 (\frac{1}{2}x - \sqrt{x}) dx = \left[\frac{2}{3}x^{3/2} - \frac{1}{4}x^2 \right]_0^4 + \left[\frac{1}{4}x^2 - \frac{2}{3}x^{3/2} \right]_4^9$$

$$= \left[\left(\frac{16}{3} - 4 \right) - 0 \right] + \left[\left(\frac{81}{4} - 18 \right) - \left(4 - \frac{16}{3} \right) \right] = \frac{81}{4} + \frac{32}{3} - 26 = \frac{59}{12}$$

For $4 < x < 9$

16. $A = \int_{-3}^3 |(8 - x^2) - x^2| dx = 2 \int_0^3 |8 - 2x^2| dx = 2 \int_0^2 (8 - 2x^2) dx + 2 \int_2^3 (2x^2 - 8) dx$

$$= 2 \left[8x - \frac{2}{3}x^3 \right]_0^2 + 2 \left[\frac{2}{3}x^3 - 8x \right]_2^3 = 2 \left[\left(16 - \frac{16}{3} \right) - 0 \right] + 2 \left[(18 - 24) - \left(\frac{16}{3} - 16 \right) \right]$$

$$= 32 - \frac{32}{3} + 20 - \frac{32}{3} = 52 - \frac{64}{3} = \frac{92}{3}$$

17. $2y^2 = 1 - y \Leftrightarrow 2y^2 + y - 1 = 0 \Leftrightarrow (2y - 1)(y + 1) = 0 \Leftrightarrow y = \frac{1}{2} \text{ or } -1$, so $x = \frac{1}{2}$ or 2 and

$$A = \int_{-1}^{1/2} [(1 - y) - 2y^2] dy = \int_{-1}^{1/2} (1 - y - 2y^2) dy = \left[y - \frac{1}{2}y^2 - \frac{2}{3}y^3 \right]_{-1}^{1/2}$$

$$= \left(\frac{1}{2} - \frac{1}{8} - \frac{1}{12} \right) - \left(-1 - \frac{1}{2} + \frac{2}{3} \right) = \frac{7}{24} - \left(-\frac{5}{6} \right) = \frac{7}{24} + \frac{20}{24} = \frac{27}{24} = \frac{9}{8}$$

18. $4x + x^2 = 12 \Leftrightarrow (x + 6)(x - 2) = 0 \Leftrightarrow x = -6 \text{ or } x = 2$, so $y = -6$ or $y = 2$ and

$$A = \int_{-6}^2 \left[\left(-\frac{1}{4}y^2 + 3 \right) - y \right] dy = \left[-\frac{1}{12}y^3 - \frac{1}{2}y^2 + 3y \right]_{-6}^2 = \left(-\frac{2}{3} - 2 + 6 \right) - (18 - 18 - 18) = 22 - \frac{2}{3} = \frac{64}{3}.$$

19. The curves intersect when $1 - y^2 = y^2 - 1 \Leftrightarrow 2 = 2y^2 \Leftrightarrow y^2 = 1 \Leftrightarrow y = \pm 1$.

$$A = \int_{-1}^1 [(1 - y^2) - (y^2 - 1)] dy$$

$$= \int_{-1}^1 2(1 - y^2) dy$$

$$= 2 \cdot 2 \int_0^1 (1 - y^2) dy$$

$$= 4 \left[y - \frac{1}{3}y^3 \right]_0^1 = 4 \left(1 - \frac{1}{3} \right) = \frac{8}{3}$$

$$20. A = 2 \int_0^1 \left[\sin\left(\frac{\pi x}{2}\right) - x \right] dx = 2 \left[-\frac{2}{\pi} \cos\left(\frac{\pi x}{2}\right) - \frac{x^2}{2} \right]_0^1 = 2 \left[\left(0 - \frac{1}{2}\right) - \left(-\frac{2}{\pi} - 0\right) \right] = \frac{4}{\pi} - 1$$

21. Notice that $\cos x = \sin 2x = 2 \sin x \cos x \Leftrightarrow$
 $2 \sin x \cos x - \cos x = 0 \Leftrightarrow \cos x (2 \sin x - 1) = 0 \Leftrightarrow$
 $2 \sin x = 1 \text{ or } \cos x = 0 \Leftrightarrow x = \frac{\pi}{6} \text{ or } \frac{\pi}{2}.$

$$\begin{aligned} A &= \int_0^{\pi/6} (\cos x - \sin 2x) dx + \int_{\pi/6}^{\pi/2} (\sin 2x - \cos x) dx \\ &= \left[\sin x + \frac{1}{2} \cos 2x \right]_0^{\pi/6} + \left[-\frac{1}{2} \cos 2x - \sin x \right]_{\pi/6}^{\pi/2} \\ &= \frac{1}{2} + \frac{1}{2} \cdot \frac{1}{2} - \left(0 + \frac{1}{2} \cdot 1\right) + \left(\frac{1}{2} - 1\right) - \left(-\frac{1}{2} \cdot \frac{1}{2} - \frac{1}{2}\right) = \frac{1}{2} \end{aligned}$$

22. $\sin x = \sin 2x = 2 \sin x \cos x$ when $\sin x = 0$ and when $\cos x = \frac{1}{2}$;
 that is, when $x = 0$ or $\frac{\pi}{3}$.

$$\begin{aligned} A &= \int_0^{\pi/3} (\sin 2x - \sin x) dx + \int_{\pi/3}^{\pi/2} (\sin x - \sin 2x) dx \\ &= \left[-\frac{1}{2} \cos 2x + \cos x \right]_0^{\pi/3} + \left[\frac{1}{2} \cos 2x - \cos x \right]_{\pi/3}^{\pi/2} \\ &= \left[-\frac{1}{2} \left(-\frac{1}{2}\right) + \frac{1}{2} \right] - \left(-\frac{1}{2} + 1\right) \\ &\quad + \left(-\frac{1}{2} - 0\right) - \left[\frac{1}{2} \left(-\frac{1}{2}\right) - \frac{1}{2}\right] = \frac{1}{2} \end{aligned}$$

23. From the graph, we see that the curves intersect at $x = 0$, $x = \frac{\pi}{2}$, and $x = \pi$. By symmetry,

$$\begin{aligned} A &= \int_0^{\pi} \left| \cos x - \left(1 - \frac{2x}{\pi}\right) \right| dx = 2 \int_0^{\pi/2} \left[\cos x - \left(1 - \frac{2x}{\pi}\right) \right] dx = 2 \int_0^{\pi/2} \left(\cos x - 1 + \frac{2x}{\pi} \right) dx \\ &= 2 \left[\sin x - x + \frac{1}{\pi} x^2 \right]_0^{\pi/2} = 2 \left[\left(1 - \frac{\pi}{2} + \frac{1}{\pi} \cdot \frac{\pi^2}{4}\right) - 0 \right] = 2 \left(1 - \frac{\pi}{2} + \frac{\pi}{4}\right) = 2 - \frac{\pi}{2} \end{aligned}$$

24. For $x > 0$, $x = x^2 - 2 \Rightarrow 0 = x^2 - x - 2 \Rightarrow 0 = (x - 2)(x + 1) \Rightarrow x = 2$. By symmetry,

$$\begin{aligned} \int_{-2}^2 [|x| - (x^2 - 2)] dx &= 2 \int_0^2 [x - (x^2 - 2)] dx = 2 \int_0^2 (x - x^2 + 2) dx = 2 \left[\frac{1}{2}x^2 - \frac{1}{3}x^3 + 2x \right]_0^2 \\ &= 2 \left(2 - \frac{8}{3} + 4 \right) = \frac{20}{3} \end{aligned}$$

25. Graph the three functions $y = x$, $y = -\frac{1}{2}x$, and $y = -2x + 3$; then determine the points of intersection: $(0, 0)$, $(1, 1)$, and $(2, -1)$.

$$\begin{aligned} A &= \int_0^1 [x - (-\frac{1}{2}x)] dx + \int_1^2 [(3 - 2x) - (-\frac{1}{2}x)] dx = \int_0^1 \frac{3}{2}x dx + \int_1^2 (3 - \frac{3}{2}x) dx \\ &= [\frac{3}{4}x^2]_0^1 + [3x - \frac{3}{4}x^2]_1^2 = (\frac{3}{4} - 0) + (6 - 3) - (3 - \frac{3}{4}) = \frac{3}{2} \end{aligned}$$

$$\begin{aligned} 26. A &= \int_0^1 [\sin \pi x - (x^2 - x)] dx + \int_1^2 [(x^2 - x) - \sin \pi x] dx \\ &= \left[-\frac{1}{\pi} \cos \pi x - \frac{1}{3}x^3 + \frac{1}{2}x^2 \right]_0^1 + \left[\frac{1}{3}x^3 - \frac{1}{2}x^2 + \frac{1}{\pi} \cos \pi x \right]_1^2 \\ &= \left(\frac{1}{\pi} - \frac{1}{3} + \frac{1}{2} \right) - \left(-\frac{1}{\pi} \right) + \left(\frac{8}{3} - 2 + \frac{1}{\pi} \right) - \left(\frac{1}{3} - \frac{1}{2} - \frac{1}{\pi} \right) \\ &= \frac{4}{\pi} + 1 \end{aligned}$$

27. An equation of the line through $(0, 0)$ and $(2, 1)$ is $y = \frac{1}{2}x$; through $(0, 0)$ and $(-1, 6)$ is $y = -6x$; through $(2, 1)$ and $(-1, 6)$ is $y = -\frac{5}{3}x + \frac{13}{3}$.

$$\begin{aligned} A &= \int_{-1}^0 \left[\left(-\frac{5}{3}x + \frac{13}{3} \right) - (-6x) \right] dx + \int_0^2 \left[\left(-\frac{5}{3}x + \frac{13}{3} \right) - \frac{1}{2}x \right] dx \\ &= \int_{-1}^0 \left(\frac{13}{3}x + \frac{13}{3} \right) dx + \int_0^2 \left(-\frac{13}{6}x + \frac{13}{3} \right) dx \\ &= \frac{13}{3} \int_{-1}^0 (x+1) dx + \frac{13}{3} \int_0^2 \left(-\frac{1}{2}x + 1 \right) dx \\ &= \frac{13}{3} \left[\frac{1}{2}x^2 + x \right]_{-1}^0 + \frac{13}{3} \left[-\frac{1}{4}x^2 + x \right]_0^2 \\ &= \frac{13}{3} \left[0 - \left(\frac{1}{2} - 1 \right) \right] + \frac{13}{3} [(-1 + 2) - 0] = \frac{13}{3} \cdot \frac{1}{2} + \frac{13}{3} \cdot 1 = \frac{13}{2} \end{aligned}$$

$$\begin{aligned} 28. A &= \int_0^2 \left[\left(-\frac{4}{5}x + 5 \right) - \left(-\frac{7}{2}x + 5 \right) \right] dx + \int_2^5 \left[\left(-\frac{4}{5}x + 5 \right) - (x - 4) \right] dx \\ &= \int_0^2 \frac{27}{10}x dx + \int_2^5 \left(-\frac{9}{5}x + 9 \right) dx \\ &= \left[\frac{27}{20}x^2 \right]_0^2 + \left[-\frac{9}{10}x^2 + 9x \right]_2^5 \\ &= \left(\frac{27}{5} - 0 \right) + \left(-\frac{45}{2} + 45 \right) - \left(-\frac{18}{5} + 18 \right) = \frac{27}{2} \end{aligned}$$

$$\begin{aligned} 29. A &= \int_{-1}^1 |x^3 - x| dx \\ &= 2 \int_0^1 (x - x^3) dx \quad [\text{by symmetry}] \\ &= 2 \left[\frac{1}{2}x^2 - \frac{1}{4}x^4 \right]_0^1 \\ &= 2 \left(\frac{1}{2} - \frac{1}{4} \right) = \frac{1}{2} \end{aligned}$$

30. The curves intersect when $\sqrt{x+2} = x \Rightarrow x+2 = x^2 \Rightarrow x^2 - x - 2 = 0 \Rightarrow (x-2)(x+1) = 0 \Rightarrow x = -1$ or 2 . $[-1$ is extraneous]

$$\begin{aligned} A &= \int_0^4 |\sqrt{x+2} - x| dx \\ &= \int_0^2 (\sqrt{x+2} - x) dx + \int_2^4 (x - \sqrt{x+2}) dx \\ &= \left[\frac{2}{3}(x+2)^{3/2} - \frac{1}{2}x^2 \right]_0^2 + \left[\frac{1}{2}x^2 - \frac{2}{3}(x+2)^{3/2} \right]_2^4 \\ &= \left(\frac{16}{3} - 2 \right) - \left(\frac{2}{3}(2\sqrt{2}) - 0 \right) + \left(8 - \frac{2}{3}(6\sqrt{6}) \right) - \left(2 - \frac{16}{3} \right) \\ &= 4 + \frac{32}{3} - \frac{4}{3}\sqrt{2} - 4\sqrt{6} = \frac{44}{3} - 4\sqrt{6} - \frac{4}{3}\sqrt{2} \end{aligned}$$

31. Let $f(x) = \cos^2\left(\frac{\pi x}{4}\right) - \sin^2\left(\frac{\pi x}{4}\right)$ and $\Delta x = \frac{1-0}{4}$.

The shaded area is given by

$$\begin{aligned} A &= \int_0^1 f(x) dx \approx M_4 \\ &= \frac{1}{4} \left[f\left(\frac{1}{8}\right) + f\left(\frac{3}{8}\right) + f\left(\frac{5}{8}\right) + f\left(\frac{7}{8}\right) \right] \\ &\approx 0.6407 \end{aligned}$$

32. The curves intersect when $\sqrt[3]{16-x^3} = x \Rightarrow$

$$16 - x^3 = x^3 \Rightarrow 2x^3 = 16 \Rightarrow x^3 = 8 \Rightarrow x = 2.$$

Let $f(x) = \sqrt[3]{16-x^3} - x$ and $\Delta x = \frac{2-0}{4}$.

The shaded area is given by

$$\begin{aligned} A &= \int_0^2 f(x) dx \approx M_4 \\ &= \frac{2}{4} \left[f\left(\frac{1}{4}\right) + f\left(\frac{3}{4}\right) + f\left(\frac{5}{4}\right) + f\left(\frac{7}{4}\right) \right] \\ &\approx 2.8144 \end{aligned}$$

33.

From the graph, we see that the curves intersect at $x = \pm a \approx \pm 1.02$, with $2 \cos x > x^2$ on $(-a, a)$. So the area of the region bounded by the curves is

$$\begin{aligned} A &= \int_{-a}^a (2 \cos x - x^2) dx = 2 \int_0^a (2 \cos x - x^2) dx \\ &= 2 \left[2 \sin x - \frac{1}{3} x^3 \right]_0^a \approx 2.70 \end{aligned}$$

34.

From the graph, we see that the curves intersect at $x = 0$ and at $x = a \approx 1.17$, with $3x - x^3 > x^4$ on $(0, a)$. So the area of the region bounded by the curves is

$$\begin{aligned} A &= \int_0^a [(3x - x^3) - x^4] dx = \left[\frac{3}{2} x^2 - \frac{1}{4} x^4 - \frac{1}{5} x^5 \right]_0^a \\ &\approx 1.15 \end{aligned}$$

35.

From the graph, we see that the curves intersect at $x = a \approx -0.72$ and at $x = b \approx 1.22$, with $\sqrt{x+1} > x^2$ on (a, b) . So the area between the curves is

$$\begin{aligned} A &= \int_a^b (\sqrt{x+1} - x^2) dx = \left[\frac{2}{3} (x+1)^{3/2} - \frac{1}{3} x^3 \right]_a^b \\ &\approx 1.38 \end{aligned}$$

36.

From the graph, we see that the curves intersect at $x = a \approx -0.83$ and $x = b \approx 1.22$, with $x \sin(x^2) > x^4 - 1$ on (a, b) . So the area of the region bounded by the curves is

$$\begin{aligned} A &= \int_a^b [x \sin(x^2) - (x^4 - 1)] dx \\ &= \left[-\frac{1}{2} \cos(x^2) - \frac{1}{5} x^5 + x \right]_a^b \approx 1.78 \end{aligned}$$

37. As the figure illustrates, the curves $y = x$ and $y = x^5 - 6x^3 + 4x$ enclose a four-part region symmetric about the origin (since $x^5 - 6x^3 + 4x$ and x are odd functions of x). The curves intersect at values of x where $x^5 - 6x^3 + 4x = x$; that is, where $x(x^4 - 6x^2 + 3) = 0$. That happens at $x = 0$ and where

$$x^2 = \frac{6 \pm \sqrt{36 - 12}}{2} = 3 \pm \sqrt{6}; \text{ that is, at } x = -\sqrt{3 + \sqrt{6}}, -\sqrt{3 - \sqrt{6}}, 0, \sqrt{3 - \sqrt{6}}, \text{ and } \sqrt{3 + \sqrt{6}}.$$

The exact area is

$$\begin{aligned} 2 \int_0^{\sqrt{3+\sqrt{6}}} |(x^5 - 6x^3 + 4x) - x| dx &= 2 \int_0^{\sqrt{3+\sqrt{6}}} |x^5 - 6x^3 + 3x| dx \\ &= 2 \int_0^{\sqrt{3-\sqrt{6}}} (x^5 - 6x^3 + 3x) dx + 2 \int_{\sqrt{3-\sqrt{6}}}^{\sqrt{3+\sqrt{6}}} (-x^5 + 6x^3 - 3x) dx \\ &\stackrel{\text{CAS}}{=} 12\sqrt{6} - 9 \end{aligned}$$

38. The inequality $x \geq 2y^2$ describes the region that lies on, or to the right of, the parabola $x = 2y^2$. The inequality $x \leq 1 - |y|$ describes the region

$$\text{that lies on, or to the left of, the curve } x = 1 - |y| = \begin{cases} 1 - y & \text{if } y \geq 0 \\ 1 + y & \text{if } y < 0 \end{cases}.$$

So the given region is the shaded region that lies between the curves.

$$\begin{aligned} \text{The graphs of } x = 1 - y \text{ and } x = 2y^2 \text{ intersect when } 1 - y &= 2y^2 \Leftrightarrow \\ 2y^2 + y - 1 &= 0 \Leftrightarrow (2y - 1)(y + 1) = 0 \Rightarrow y = \frac{1}{2} \text{ (for } y \geq 0). \end{aligned}$$

By symmetry,

$$A = 2 \int_0^{1/2} [(1 - y) - 2y^2] dy = 2 \left[-\frac{2}{3} y^3 - \frac{1}{2} y^2 + y \right]_0^{1/2} = 2 \left[\left(-\frac{1}{12} - \frac{1}{8} + \frac{1}{2} \right) - 0 \right] = 2 \left(\frac{7}{24} \right) = \frac{7}{12}.$$

39. 1 second = $\frac{1}{3600}$ hour, so $10 \text{ s} = \frac{1}{360}$ h. With the given data, we can take $n = 5$ to use the Midpoint Rule.

$$\Delta t = \frac{1/360 - 0}{5} = \frac{1}{1800}, \text{ so}$$

$$\begin{aligned} \text{distance}_{\text{Kelly}} - \text{distance}_{\text{Chris}} &= \int_0^{1/360} v_K dt - \int_0^{1/360} v_C dt = \int_0^{1/360} (v_K - v_C) dt \\ &\approx M_5 = \frac{1}{1800} [(v_K - v_C)(1) + (v_K - v_C)(3) + (v_K - v_C)(5) \\ &\quad + (v_K - v_C)(7) + (v_K - v_C)(9)] \\ &= \frac{1}{1800} [(22 - 20) + (52 - 46) + (71 - 62) + (86 - 75) + (98 - 86)] \\ &= \frac{1}{1800} (2 + 6 + 9 + 11 + 12) = \frac{1}{1800} (40) = \frac{1}{45} \text{ mile, or } 117\frac{1}{3} \text{ feet} \end{aligned}$$

40. If x = distance from left end of pool and $w = w(x)$ = width at x , then the Midpoint Rule with $n = 4$ and

$$\Delta x = \frac{b - a}{n} = \frac{8 \cdot 2 - 0}{4} = 4 \text{ gives Area} = \int_0^{16} w dx \approx 4(6.2 + 6.8 + 5.0 + 4.8) = 4(22.8) = 91.2 \text{ m}^2.$$

41. We know that the area under curve A between $t = 0$ and $t = x$ is $\int_0^x v_A(t) dt = s_A(x)$, where $v_A(t)$ is the velocity of car A and s_A is its displacement. Similarly, the area under curve B between $t = 0$ and $t = x$ is $\int_0^x v_B(t) dt = s_B(x)$.

- After one minute, the area under curve A is greater than the area under curve B . So car A is ahead after one minute.
- The area of the shaded region has numerical value $s_A(1) - s_B(1)$, which is the distance by which A is ahead of B after 1 minute.
- After two minutes, car B is traveling faster than car A and has gained some ground, but the area under curve A from $t = 0$ to $t = 2$ is still greater than the corresponding area for curve B , so car A is still ahead.
- From the graph, it appears that the area between curves A and B for $0 \leq t \leq 1$ (when car A is going faster), which corresponds to the distance by which car A is ahead, seems to be about 3 squares. Therefore, the cars will be side by side at the time x where the area between the curves for $1 \leq t \leq x$ (when car B is going faster) is the same as the area for $0 \leq t \leq 1$. From the graph, it appears that this time is $x \approx 2.2$. So the cars are side by side when $t \approx 2.2$ minutes.

42. The area under $R'(x)$ from $x = 50$ to $x = 100$ represents the change in revenue, and the area under $C'(x)$ from $x = 50$ to $x = 100$ represents the change in cost. The shaded region represents the difference between these two values; that is, the increase in profit as the production level increases from 50 units to 100 units. We use the Midpoint Rule with $n = 5$ and $\Delta x = 10$:

$$\begin{aligned} M_5 &= \Delta x \{ [R'(55) - C'(55)] + [R'(65) - C'(65)] + [R'(75) - C'(75)] \\ &\quad + [R'(85) - C'(85)] + [R'(95) - C'(95)] \} \\ &\approx 10(2.40 - 0.85 + 2.20 - 0.90 + 2.00 - 1.00 + 1.80 - 1.10 + 1.70 - 1.20) \\ &= 10(5.05) = 50.5 \text{ thousand dollars} \end{aligned}$$

Using M_1 would give us $50(2 - 1) = 50$ thousand dollars.

43.

To graph this function, we must first express it as a combination of explicit functions of y ; namely, $y = \pm x\sqrt{x+3}$. We can see from the graph that the loop extends from $x = -3$ to $x = 0$, and that by symmetry, the area we seek is just twice the area under the top half of the curve on this interval, the equation of the top half being $y = x\sqrt{x+3}$. So the area is $A = 2 \int_{-3}^0 (-x\sqrt{x+3}) dx$. We substitute $u = x + 3$, so $du = dx$ and the limits change to 0 and 3, and we get

$$\begin{aligned} A &= -2 \int_0^3 [(u-3)\sqrt{u}] du = -2 \int_0^3 (u^{3/2} - 3u^{1/2}) du \\ &= -2 \left[\frac{2}{5} u^{5/2} - 2u^{3/2} \right]_0^3 = -2 \left[\frac{2}{5} (3^2 \sqrt{3}) - 2(3\sqrt{3}) \right] = \frac{24}{5} \sqrt{3} \end{aligned}$$

44.

We start by finding the equation of the tangent line to $y = x^2$ at the point $(1, 1)$: $y' = 2x$, so the slope of the tangent is $2(1) = 2$, and its equation is $y - 1 = 2(x - 1)$, or $y = 2x - 1$. We would need two integrals to integrate with respect to x , but only one to integrate with respect to y .

$$\begin{aligned} A &= \int_0^1 \left[\frac{1}{2}(y+1) - \sqrt{y} \right] dy = \left[\frac{1}{4}y^2 + \frac{1}{2}y - \frac{2}{3}y^{3/2} \right]_0^1 \\ &= \frac{1}{4} + \frac{1}{2} - \frac{2}{3} = \frac{1}{12} \end{aligned}$$

45.

By the symmetry of the problem, we consider only the first quadrant, where $y = x^2 \Rightarrow x = \sqrt{y}$. We are looking for a number b such that $\int_0^b \sqrt{y} dy = \int_b^4 \sqrt{y} dy \Rightarrow \frac{2}{3} [y^{3/2}]_0^b = \frac{2}{3} [y^{3/2}]_b^4 \Rightarrow b^{3/2} = 4^{3/2} - b^{3/2} \Rightarrow 2b^{3/2} = 8 \Rightarrow b^{3/2} = 4 \Rightarrow b = 4^{2/3} \approx 2.52$.

$$\begin{aligned} 46. \text{ (a) We want to choose } a \text{ so that } \int_1^a \frac{1}{x^2} dx &= \int_a^4 \frac{1}{x^2} dx \Rightarrow \left[\frac{-1}{x} \right]_1^a = \left[\frac{-1}{x} \right]_a^4 \Rightarrow -\frac{1}{a} + 1 = -\frac{1}{4} + \frac{1}{a} \\ &\Rightarrow \frac{5}{4} = \frac{2}{a} \Rightarrow a = \frac{8}{5}. \end{aligned}$$

(b) The area under the curve $y = 1/x^2$ from $x = 1$ to $x = 4$ is $\frac{3}{4}$ [take $a = 4$ in the first integral in part (a)]. Now the line $y = b$ must intersect the curve $x = 1/\sqrt{y}$ and not the line $x = 4$, since the area under the line $y = 1/4^2$ from $x = 1$ to $x = 4$ is only $\frac{3}{16}$, which is less than half of $\frac{3}{4}$. We want to choose b so that the upper area in the

diagram is half of the total area under the curve $y = \frac{1}{x^2}$ from $x = 1$ to $x = 4$. This implies that

$$\begin{aligned}\int_b^1 (1/\sqrt{y} - 1) dy &= \frac{1}{2} \cdot \frac{3}{4} \Rightarrow [2\sqrt{y} - y]_b^1 = \frac{3}{8} \Rightarrow \\ 1 - 2\sqrt{b} + b &= \frac{3}{8} \Rightarrow b - 2\sqrt{b} + \frac{5}{8} = 0. \text{ Letting } c = \sqrt{b}, \text{ we get} \\ c^2 - 2c + \frac{5}{8} &= 0 \Rightarrow 8c^2 - 16c + 5 = 0. \text{ Thus,} \\ c &= \frac{16 \pm \sqrt{256 - 160}}{16} = 1 \pm \frac{\sqrt{6}}{4}. \text{ But } c = \sqrt{b} < 1 \Rightarrow c = 1 - \frac{\sqrt{6}}{4} \Rightarrow \\ b &= c^2 = 1 + \frac{3}{8} - \frac{\sqrt{6}}{2} = \frac{1}{8}(11 - 4\sqrt{6}) \approx 0.1503.\end{aligned}$$

47. We first assume that $c > 0$, since c can be replaced by $-c$ in both equations without changing the graphs, and if $c = 0$ the curves do not enclose a region. We see from the graph that the enclosed area A lies between $x = -c$ and $x = c$, and by symmetry, it is equal to four times the area in the first quadrant.

The enclosed area is

$$\begin{aligned}A &= 4 \int_0^c (c^2 - x^2) dx = 4 \left[c^2 x - \frac{1}{3} x^3 \right]_0^c \\ &= 4 \left(c^3 - \frac{1}{3} c^3 \right) = 4 \left(\frac{2}{3} c^3 \right) = \frac{8}{3} c^3\end{aligned}$$

$$\text{So } A = 576 \Leftrightarrow \frac{8}{3} c^3 = 576 \Leftrightarrow c^3 = 216 \Leftrightarrow c = \sqrt[3]{216} = 6.$$

Note that $c = -6$ is another solution, since the graphs are the same.

It appears from the diagram that the curves $y = \cos x$ and $y = \cos(x - c)$ intersect halfway between 0 and c , namely, when $x = c/2$. We can verify that this is indeed true by noting that $\cos(c/2 - c) = \cos(-c/2) = \cos(c/2)$. The point where $\cos(x - c)$ crosses the x -axis is $x = \frac{\pi}{2} + c$. So we require that $\int_0^{c/2} [\cos x - \cos(x - c)] dx = - \int_{\pi/2+c}^{\pi} \cos(x - c) dx$ (the negative sign on the RHS is needed since the second area is beneath the x -axis) $\Leftrightarrow$

$$\begin{aligned}[\sin x - \sin(x - c)]_0^{c/2} &= -[\sin(x - c)]_{\pi/2+c}^{\pi} \Rightarrow \\ [\sin(c/2) - \sin(-c/2)] - [-\sin(-c)] &= -\sin(\pi - c) + \sin[(\frac{\pi}{2} + c) - c] \Leftrightarrow \\ 2 \sin(c/2) - \sin c &= -\sin c + 1. \text{ [Here we have used the oddness of the sine function, and the fact that} \\ \sin(\pi - c) &= \sin c]. \text{ So } 2 \sin(c/2) = 1 \Leftrightarrow \sin(c/2) = \frac{1}{2} \Leftrightarrow c/2 = \frac{\pi}{6} \Leftrightarrow c = \frac{\pi}{3}.\end{aligned}$$

$$\begin{aligned}49. A &= \int_1^2 \left(\frac{1}{x} - \frac{1}{x^2} \right) dx = \left[\ln x + \frac{1}{x} \right]_1^2 \\ &= \left(\ln 2 + \frac{1}{2} \right) - (\ln 1 + 1) \\ &= \ln 2 - \frac{1}{2} \approx 0.19\end{aligned}$$

$$\begin{aligned}
 50. A &= \int_0^{\pi/2} (e^x - \sin x) dx \\
 &= [e^x + \cos x]_0^{\pi/2} \\
 &= (e^{\pi/2} + 0) - (1 + 1) \\
 &= e^{\pi/2} - 2
 \end{aligned}$$

$$\begin{aligned}
 51. \text{ The curves intersect when } x^2 = \frac{2}{x^2 + 1} &\Leftrightarrow x^4 + x^2 = 2 \Leftrightarrow x^4 + x^2 - 2 = 0 \Leftrightarrow \\
 (x^2 + 2)(x^2 - 1) = 0 &\Leftrightarrow x^2 = 1 \Leftrightarrow x = \pm 1.
 \end{aligned}$$

$$\begin{aligned}
 A &= \int_{-1}^1 \left(\frac{2}{x^2 + 1} - x^2 \right) dx \\
 &= 2 \int_0^1 \left(\frac{2}{x^2 + 1} - x^2 \right) dx \\
 &= 2 \left[2 \tan^{-1} x - \frac{1}{3} x^3 \right]_0^1 = 2 \left(2 \cdot \frac{\pi}{4} - \frac{1}{3} \right) \\
 &= \pi - \frac{2}{3} \approx 2.47
 \end{aligned}$$

52. The curve and the line will determine a region when they intersect at two or more points. So we solve the equation

$$\begin{aligned}
 x/(x^2 + 1) &= mx \Rightarrow x = x(mx^2 + m) \Rightarrow \\
 x(mx^2 + m) - x &= 0 \Rightarrow x(mx^2 + m - 1) = 0 \Rightarrow \\
 x = 0 \text{ or } mx^2 + m - 1 &= 0 \Rightarrow x = 0 \text{ or } x^2 = \frac{1 - m}{m} \Rightarrow
 \end{aligned}$$

$x = 0$ or $x = \pm \sqrt{\frac{1}{m} - 1}$. Note that if $m = 1$, this has only the solution $x = 0$, and no region is determined. But if

$1/m - 1 > 0 \Leftrightarrow 1/m > 1 \Leftrightarrow 0 < m < 1$, then there are two solutions. [Another way of seeing this is to observe that the slope of the tangent to $y = x/(x^2 + 1)$ at the origin is $y' = 1$ and therefore we must have $0 < m < 1$.] Note that we cannot just integrate between the positive and negative roots, since the curve and the line cross at the origin. Since mx and $x/(x^2 + 1)$ are both odd functions, the total area is twice the area between the curves on the interval $[0, \sqrt{1/m - 1}]$. So the total area enclosed is

$$\begin{aligned}
 2 \int_0^{\sqrt{1/m-1}} \left[\frac{x}{x^2 + 1} - mx \right] dx &= 2 \left[\frac{1}{2} \ln(x^2 + 1) - \frac{1}{2} mx^2 \right]_0^{\sqrt{1/m-1}} \\
 &= [\ln(1/m - 1 + 1) - m(1/m - 1)] - (\ln 1 - 0) \\
 &= \ln(1/m) - 1 + m = m - \ln m - 1
 \end{aligned}$$

6.2 Volumes

1. A cross-section is circular with radius x^2 , so its area is $A(x) = \pi(x^2)^2$.

$$V = \int_0^1 A(x) dx = \int_0^1 \pi(x^2)^2 dx = \pi \int_0^1 x^4 dx = \pi \left[\frac{1}{5} x^5 \right]_0^1 = \frac{\pi}{5}$$

2. $x + 2y = 2 \Leftrightarrow y = 1 - \frac{1}{2}x$, so a cross-section is circular with radius $1 - \frac{1}{2}x$, and its area is $A(x) = \pi(1 - \frac{1}{2}x)^2$.

$$\begin{aligned} V &= \int_0^2 \pi y^2 dx = \pi \int_0^2 \left(1 - \frac{1}{2}x\right)^2 dx = \pi \int_0^2 \left(1 - x + \frac{1}{4}x^2\right) dx = \pi \left[x - \frac{1}{2}x^2 + \frac{1}{12}x^3 \right]_0^2 \\ &= \pi \left(2 - 2 + \frac{2}{3} \right) = \frac{2}{3}\pi \end{aligned}$$

3. A cross-section is a disk with radius $1/x$, so its area is $A(x) = \pi(1/x)^2$.

$$V = \int_1^2 A(x) dx = \int_1^2 \pi \left(\frac{1}{x} \right)^2 dx = \pi \int_1^2 \frac{1}{x^2} dx = \pi \left[-\frac{1}{x} \right]_1^2 = \pi \left[-\frac{1}{2} - (-1) \right] = \frac{\pi}{2}$$

4. A cross-section is circular with radius $\sqrt{x-1}$, so its area is $A(x) = \pi(\sqrt{x-1})^2 = \pi(x-1)$.

$$V = \int_2^5 A(x) dx = \int_2^5 \pi(x-1) dx = \pi \left[\frac{1}{2}x^2 - x \right]_2^5 = \pi \left(\frac{25}{2} - 5 - \frac{4}{2} + 2 \right) = \frac{15}{2}\pi$$

5. A cross-section is a disk with radius $\sqrt{y}$, so its area is $A(y) = \pi(\sqrt{y})^2$.

$$V = \int_0^4 A(y) dy = \int_0^4 \pi(\sqrt{y})^2 dy = \pi \int_0^4 y dy = \pi \left[\frac{1}{2}y^2 \right]_0^4 = 8\pi$$

6. A cross-section is a disk with radius $y - y^2$, so its area is $A(y) = \pi(y - y^2)^2$.

$$\begin{aligned} V &= \int_0^1 A(y) dy = \int_0^1 \pi(y - y^2)^2 dy = \pi \int_0^1 (y^4 - 2y^3 + y^2) dy = \pi \left[\frac{1}{5}y^5 - \frac{1}{2}y^4 + \frac{1}{3}y^3 \right]_0^1 \\ &= \pi \left(\frac{1}{5} - \frac{1}{2} + \frac{1}{3} \right) = \frac{\pi}{30} \end{aligned}$$

7. A cross-section is a washer (annulus) with inner radius x^2 and outer radius $\sqrt{x}$, so its area is $A(x) = \pi(\sqrt{x})^2 - \pi(x^2)^2 = \pi(x - x^4)$.

$$V = \int_0^1 A(x) dx = \pi \int_0^1 (x - x^4) dx = \pi \left[\frac{1}{2}x^2 - \frac{1}{5}x^5 \right]_0^1 = \pi \left(\frac{1}{2} - \frac{1}{5} \right) = \frac{3\pi}{10}$$

8. A cross-section is a washer with inner radius 1 and outer radius $\sec x$, so its area is

$$A(x) = \pi(\sec x)^2 - \pi(1)^2 = \pi(\sec^2 x - 1).$$

$$V = \int_{-1}^1 A(x) dx = \int_{-1}^1 \pi(\sec^2 x - 1) dx = 2\pi \int_0^1 (\sec^2 x - 1) dx = 2\pi[\tan x - x]_0^1 = 2\pi(\tan 1 - 1) \approx 3.5023$$

9. A cross-section is a washer with inner radius y^2 and outer radius $2y$, so its area is

$$A(y) = \pi(2y)^2 - \pi(y^2)^2 = \pi(4y^2 - y^4).$$

$$V = \int_0^2 A(y) dy = \pi \int_0^2 (4y^2 - y^4) dy = \pi \left[\frac{4}{3}y^3 - \frac{1}{5}y^5 \right]_0^2 = \pi \left(\frac{32}{3} - \frac{32}{5} \right) = \frac{64\pi}{15}$$

10. $y = x^{2/3} \Leftrightarrow x = y^{3/2}$, so a cross-section is a washer with inner radius $y^{3/2}$ and outer radius 1, and its area is

$$A(y) = \pi(1)^2 - \pi(y^{3/2})^2 = \pi(1 - y^3).$$

$$V = \int_0^1 A(y) dy = \pi \int_0^1 (1 - y^3) dy = \pi \left[y - \frac{1}{4}y^4 \right]_0^1 = \frac{3}{4}\pi$$

11. A cross-section is a washer with inner radius $1 - \sqrt{x}$ and outer radius $1 - x$, so its area is

$$A(x) = \pi(1 - x)^2 - \pi(1 - \sqrt{x})^2 = \pi[(1 - 2x + x^2) - (1 - 2\sqrt{x} + x)] = \pi(-3x + x^2 + 2\sqrt{x}).$$

$$\begin{aligned} V &= \int_0^1 A(x) dx = \pi \int_0^1 (-3x + x^2 + 2\sqrt{x}) dx \\ &= \pi \left[-\frac{3}{2}x^2 + \frac{1}{3}x^3 + \frac{4}{3}x^{3/2} \right]_0^1 = \pi \left(-\frac{3}{2} + \frac{5}{3} \right) = \frac{\pi}{6} \end{aligned}$$

12. A cross-section is circular with radius $4 - x^2$, so its area is $A(x) = \pi(4 - x^2)^2 = \pi(16 - 8x^2 + x^4)$.

$$\begin{aligned} V &= \int_{-2}^2 A(x) dx = 2 \int_0^2 A(x) dx = 2\pi \int_0^2 (16 - 8x^2 + x^4) dx = 2\pi \left[16x - \frac{8}{3}x^3 + \frac{1}{5}x^5 \right]_0^2 \\ &= 2\pi \left(32 - \frac{64}{3} + \frac{32}{5} \right) = 64\pi \left(1 - \frac{2}{3} + \frac{1}{5} \right) = 64\pi \cdot \frac{8}{15} = \frac{512\pi}{15} \end{aligned}$$

13. A cross-section is an annulus with inner radius $2 - 1$ and outer radius $2 - x^4$, so its area is

$$A(x) = \pi(2 - x^4)^2 - \pi(2 - 1)^2 = \pi(3 - 4x^4 + x^8).$$

$$\begin{aligned} V &= \int_{-1}^1 A(x) dx = 2 \int_0^1 A(x) dx = 2\pi \int_0^1 (3 - 4x^4 + x^8) dx = 2\pi \left[3x - \frac{4}{5}x^5 + \frac{1}{9}x^9 \right]_0^1 \\ &= 2\pi \left(3 - \frac{4}{5} + \frac{1}{9} \right) = \frac{208}{45}\pi \end{aligned}$$

$$\begin{aligned}
 14. V &= \int_1^3 \pi \left\{ \left[\frac{1}{x^2} - (-1) \right]^2 - [0 - (-1)]^2 \right\} dx = \pi \int_1^3 \left[\left(\frac{1}{x^2} + 1 \right)^2 - 1^2 \right] dx = \pi \int_1^3 \left(\frac{1}{x^4} + \frac{2}{x^2} \right) dx \\
 &= \pi \left[-\frac{1}{3x^3} - \frac{2}{x} \right]_1^3 = \pi \left[\left(-\frac{1}{81} - \frac{2}{3} \right) - \left(-\frac{1}{3} - 2 \right) \right] = \frac{134\pi}{81}
 \end{aligned}$$

$$\begin{aligned}
 15. V &= \int_{-1}^1 \pi (1 - y^2)^2 dy = 2 \int_0^1 \pi (1 - y^2)^2 dy = 2\pi \int_0^1 (1 - 2y^2 + y^4) dy \\
 &= 2\pi \left[y - \frac{2}{3}y^3 + \frac{1}{5}y^5 \right]_0^1 = 2\pi \cdot \frac{8}{15} = \frac{16}{15}\pi
 \end{aligned}$$

16. $y = \sqrt{x} \Rightarrow x = y^2$, so the outer radius is $2 - y^2$.

$$\begin{aligned}
 V &= \int_0^1 \pi \left[(2 - y^2)^2 - (2 - y)^2 \right] dy = \pi \int_0^1 [(4 - 4y^2 + y^4) - (4 - 4y + y^2)] dy \\
 &= \pi \int_0^1 (y^4 - 5y^2 + 4y) dy = \pi \left[\frac{1}{5}y^5 - \frac{5}{3}y^3 + 2y^2 \right]_0^1 = \pi \left(\frac{1}{5} - \frac{5}{3} + 2 \right) = \frac{8}{15}\pi
 \end{aligned}$$

17. $y = x^2 \Rightarrow x = \sqrt{y}$ for $x \geq 0$. The outer radius is the distance from $x = -1$ to $x = \sqrt{y}$ and the inner radius is the distance from $x = -1$ to $x = y^2$.

$$\begin{aligned} V &= \int_0^1 \pi \left\{ [\sqrt{y} - (-1)]^2 - [y^2 - (-1)]^2 \right\} dy = \pi \int_0^1 [(\sqrt{y} + 1)^2 - (y^2 + 1)^2] dy \\ &= \pi \int_0^1 (y + 2\sqrt{y} + 1 - y^4 - 2y^2 - 1) dy = \pi \int_0^1 (y + 2\sqrt{y} - y^4 - 2y^2) dy \\ &= \pi \left[\frac{1}{2}y^2 + \frac{4}{3}y^{3/2} - \frac{1}{5}y^5 - \frac{2}{3}y^3 \right]_0^1 = \pi \left(\frac{1}{2} + \frac{4}{3} - \frac{1}{5} - \frac{2}{3} \right) = \frac{29}{30}\pi \end{aligned}$$

18. For $0 \leq y < 2$, a cross-section is an annulus with inner radius $2 - 1$ and outer radius $4 - 1$, the area of which is $A_1(y) = \pi(4 - 1)^2 - \pi(2 - 1)^2$. For $2 \leq y \leq 4$, a cross-section is an annulus with inner radius $y - 1$ and outer radius $4 - 1$, the area of which is $A_2(y) = \pi(4 - 1)^2 - \pi(y - 1)^2$.

$$\begin{aligned} V &= \int_0^4 A(y) dy = \pi \int_0^2 [(4 - 1)^2 - (2 - 1)^2] dy + \pi \int_2^4 [(4 - 1)^2 - (y - 1)^2] dy \\ &= \pi [8y]_0^2 + \pi \int_2^4 (8 + 2y - y^2) dy = 16\pi + \pi \left[8y + y^2 - \frac{1}{3}y^3 \right]_2^4 \\ &= 16\pi + \pi \left[(32 + 16 - \frac{64}{3}) - (16 + 4 - \frac{8}{3}) \right] = \frac{76}{3}\pi \end{aligned}$$

19. $\mathcal{R}_1$ about OA (the line $y = 0$): $V = \int_0^1 A(x) dx = \int_0^1 \pi(x^3)^2 dx = \pi \int_0^1 x^6 dx = \pi \left[\frac{1}{7}x^7 \right]_0^1 = \frac{\pi}{7}$

20. $\mathcal{R}_1$ about OC (the line $x = 0$):

$$V = \int_0^1 A(y) dy = \int_0^1 [\pi(1)^2 - \pi(\sqrt[3]{y})^2] dy = \pi \int_0^1 (1 - y^{2/3}) dy = \pi \left[y - \frac{3}{5}y^{5/3} \right]_0^1 = \pi \left(1 - \frac{3}{5} \right) = \frac{2\pi}{5}$$

21. $\mathcal{R}_1$ about AB (the line $x = 1$):

$$\begin{aligned} V &= \int_0^1 A(y) dy = \int_0^1 \pi(1 - \sqrt[3]{y})^2 dy = \pi \int_0^1 (1 - 2y^{1/3} + y^{2/3}) dy \\ &= \pi \left[y - \frac{3}{2}y^{4/3} + \frac{3}{5}y^{5/3} \right]_0^1 = \pi \left(1 - \frac{3}{2} + \frac{3}{5} \right) = \frac{\pi}{10} \end{aligned}$$

22. $\mathcal{R}_1$ about BC (the line $y = 1$):

$$\begin{aligned} V &= \int_0^1 A(x) dx = \int_0^1 [\pi(1)^2 - \pi(1 - x^3)^2] dx = \pi \int_0^1 [1 - (1 - 2x^3 + x^6)] dx \\ &= \pi \int_0^1 (2x^3 - x^6) dx = \pi \left[\frac{1}{2}x^4 - \frac{1}{7}x^7 \right]_0^1 = \pi \left(\frac{1}{2} - \frac{1}{7} \right) = \frac{5\pi}{14} \end{aligned}$$

23. $\mathcal{R}_2$ about OA (the line $y = 0$):

$$V = \int_0^1 A(x) dx = \int_0^1 [\pi(1)^2 - \pi(\sqrt{x})^2] dx = \pi \int_0^1 (1 - x) dx = \pi \left[x - \frac{1}{2}x^2 \right]_0^1 = \pi \left(1 - \frac{1}{2} \right) = \frac{\pi}{2}$$

24. $\mathcal{R}_2$ about OC (the line $x = 0$): $V = \int_0^1 A(y) dy = \int_0^1 \pi(y^2)^2 dy = \pi \int_0^1 y^4 dy = \pi \left[\frac{1}{5} y^5 \right]_0^1 = \frac{\pi}{5}$

25. $\mathcal{R}_2$ about AB (the line $x = 1$):

$$V = \int_0^1 A(y) dy = \int_0^1 [\pi(1)^2 - \pi(1 - y^2)^2] dy = \pi \int_0^1 [1 - (1 - 2y^2 + y^4)] dy$$

$$= \pi \int_0^1 (2y^2 - y^4) dy = \pi \left[\frac{2}{3} y^3 - \frac{1}{5} y^5 \right]_0^1 = \pi \left(\frac{2}{3} - \frac{1}{5} \right) = \frac{7\pi}{15}$$

26. $\mathcal{R}_2$ about BC (the line $y = 1$):

$$V = \int_0^1 A(x) dx = \int_0^1 \pi(1 - \sqrt{x})^2 dx = \pi \int_0^1 (1 - 2x^{1/2} + x) dx$$

$$= \pi \left[x - \frac{4}{3} x^{3/2} + \frac{1}{2} x^2 \right]_0^1 = \pi \left(1 - \frac{4}{3} + \frac{1}{2} \right) = \frac{\pi}{6}$$

27. $\mathcal{R}_3$ about OA (the line $y = 0$):

$$V = \int_0^1 A(x) dx = \int_0^1 [\pi(\sqrt{x})^2 - \pi(x^3)^2] dx = \pi \int_0^1 (x - x^6) dx = \pi \left[\frac{1}{2} x^2 - \frac{1}{7} x^7 \right]_0^1 = \pi \left(\frac{1}{2} - \frac{1}{7} \right) = \frac{5\pi}{14}.$$

Note: Let $\mathcal{R} = \mathcal{R}_1 + \mathcal{R}_2 + \mathcal{R}_3$. If we rotate $\mathcal{R}$ about any of the segments OA , OC , AB , or BC , we obtain a right circular cylinder of height 1 and radius 1. Its volume is $\pi r^2 h = \pi(1)^2 \cdot 1 = \pi$. As a check for Exercises 19, 23, and 27, we can add the answers, and that sum must equal π . Thus, $\frac{\pi}{7} + \frac{\pi}{2} + \frac{5\pi}{14} = \left(\frac{2+7+5}{14} \right) \pi = \pi$.

28. $\mathcal{R}_3$ about OC (the line $x = 0$):

$$V = \int_0^1 A(y) dy = \int_0^1 [\pi(\sqrt[3]{y})^2 - \pi(y^2)^2] dy = \pi \int_0^1 (y^{2/3} - y^4) dy$$

$$= \pi \left[\frac{3}{5} y^{5/3} - \frac{1}{5} y^5 \right]_0^1 = \pi \left(\frac{3}{5} - \frac{1}{5} \right) = \frac{2\pi}{5}$$

Note: See the note in Exercise 27. For Exercises 20, 24, and 28, we have $\frac{2\pi}{5} + \frac{\pi}{5} + \frac{2\pi}{5} = \pi$.

29. $\mathcal{R}_3$ about AB (the line $x = 1$):

$$V = \int_0^1 A(y) dy = \int_0^1 [\pi(1 - y^2)^2 - \pi(1 - \sqrt[3]{y})^2] dy = \pi \int_0^1 [(1 - 2y^2 + y^4) - (1 - 2y^{1/3} + y^{2/3})] dy$$

$$= \pi \int_0^1 (-2y^2 + y^4 + 2y^{1/3} - y^{2/3}) dy = \pi \left[-\frac{2}{3} y^3 + \frac{1}{5} y^5 + \frac{3}{2} y^{4/3} - \frac{3}{5} y^{5/3} \right]_0^1$$

$$= \pi \left(-\frac{2}{3} + \frac{1}{5} + \frac{3}{2} - \frac{3}{5} \right) = \frac{13\pi}{30}$$

Note: See the note in Exercise 27. For Exercises 21, 25, and 29, we have $\frac{\pi}{10} + \frac{7\pi}{15} + \frac{13\pi}{30} = \left(\frac{3+14+13}{30} \right) \pi = \pi$.

30. $\mathcal{R}_3$ about BC (the line $y = 1$):

$$V = \int_0^1 A(x) dx = \int_0^1 [\pi(1 - x^3)^2 - \pi(1 - \sqrt{x})^2] dx$$

$$= \pi \int_0^1 [(1 - 2x^3 + x^6) - (1 - 2x^{1/2} + x)] dx = \pi \int_0^1 (-2x^3 + x^6 + 2x^{1/2} - x) dx$$

$$= \pi \left[-\frac{1}{2} x^4 + \frac{1}{7} x^7 + \frac{4}{3} x^{3/2} - \frac{1}{2} x^2 \right]_0^1 = \pi \left(-\frac{1}{2} + \frac{1}{7} + \frac{4}{3} - \frac{1}{2} \right) = \frac{10\pi}{21}$$

Note: See the note in Exercise 27. For Exercises 22, 26, and 30, we have $\frac{5\pi}{14} + \frac{\pi}{6} + \frac{10\pi}{21} = \left(\frac{15+7+20}{42} \right) \pi = \pi$.

31. $V = \pi \int_0^{\pi/4} (1 - \tan^3 x)^2 dx$

- 32.
- $y = (x - 2)^4$
- and
- $8x - y = 16$
- intersect when

$$(x - 2)^4 = 8x - 16 = 8(x - 2) \Leftrightarrow$$

$$(x - 2)^4 - 8(x - 2) = 0 \Leftrightarrow (x - 2)[(x - 2)^3 - 8] = 0$$

$$\Leftrightarrow x - 2 = 0 \text{ or } x - 2 = 2 \Leftrightarrow x = 2 \text{ or } 4.$$

$$y = (x - 2)^4 \Rightarrow x - 2 = \pm \sqrt[4]{y} \Rightarrow x = 2 + \sqrt[4]{y}$$

$$[\text{since } x \geq 2, 8x - y = 16 \Rightarrow 8x = y + 16 \Rightarrow$$

$$x = \frac{1}{8}y + 2.$$

$$V = \pi \int_0^{16} \left\{ \left[10 - \left(\frac{1}{8}y + 2 \right) \right]^2 - \left[10 - (2 + \sqrt[4]{y}) \right]^2 \right\} dy$$

$$\begin{aligned} 33. V &= \pi \int_0^\pi [(1 - 0)^2 - (1 - \sin x)^2] dx \\ &= \pi \int_0^\pi [1^2 - (1 - \sin x)^2] dx \end{aligned}$$

$$34. V = \pi \int_0^\pi [(\sin x + 2)^2 - 2^2] dx$$

$$\begin{aligned} 35. V &= \pi \int_{-\sqrt{8}}^{\sqrt{8}} \left\{ [3 - (-2)]^2 - [\sqrt{y^2 + 1} - (-2)]^2 \right\} dy \\ &= \pi \int_{-2\sqrt{2}}^{2\sqrt{2}} \left[5^2 - (\sqrt{1 + y^2} + 2)^2 \right] dy \end{aligned}$$

36. Solve the equations for
- x
- :
- $(y - 1)^2 = 4 - x \Leftrightarrow x = 4 - (y - 1)^2$
- and
- $2x + 3y = 6 \Leftrightarrow x = 3 - \frac{3}{2}y$
- .

The points of intersection of the two curves are $(3, 0)$ and $(-\frac{9}{4}, \frac{7}{2})$. Therefore,

$$\begin{aligned} V &= \pi \int_0^{7/2} \left\{ [4 - (y - 1)^2 - (-5)]^2 - [3 - \frac{3}{2}y - (-5)]^2 \right\} dy \\ &= \pi \int_0^{7/2} \left\{ [9 - (y - 1)^2]^2 - (8 - \frac{3}{2}y)^2 \right\} dy \end{aligned}$$

37. We see from the graph in Exercise 6.1.35 that the x -coordinates of the points of intersection are $x = a \approx -0.72$ and $x = b \approx 1.22$, with $\sqrt{x+1} > x^2$ on the interval (a, b) , so the volume of revolution is

$$\pi \int_a^b [(\sqrt{x+1})^2 - (x^2)^2] dx = \pi \int_a^b (x+1-x^4) dx = \pi \left[\frac{1}{2}x^2 + x - \frac{1}{5}x^5 \right]_a^b \approx 5.80.$$

38. We see from the graph in Exercise 6.1.34 that the x -coordinates of the points of intersection are $x = 0$ and $x = a \approx 1.17$, with $3x - x^3 > x^4$ on the interval $(0, a)$, so the volume of revolution is

$$\begin{aligned} \pi \int_0^a [(3x - x^3)^2 - (x^4)^2] dx &= \pi \int_0^a (9x^2 - 6x^4 + x^6 - x^8) dx \\ &= \pi \left[3x^3 - \frac{6}{5}x^5 + \frac{1}{7}x^7 - \frac{1}{9}x^9 \right]_0^a \approx 6.74 \end{aligned}$$

39. $V = \pi \int_0^\pi \{ [\sin^2 x - (-1)]^2 - [0 - (-1)]^2 \} dx$
 $\stackrel{\text{CAS}}{=} \frac{11}{8}\pi^2$

40. $V = \pi \int_0^2 \{ [2 - (x^2 - 2x)]^2 - [2 - x \cos(\pi x/4)]^2 \} dx$
 $\stackrel{\text{CAS}}{=} \frac{4(19\pi^2 + 120\pi - 210)}{15\pi}$

41. $\pi \int_0^{\pi/2} \cos^2 x dx$ describes the volume of the solid obtained by rotating the region $\mathcal{R} = \{(x, y) \mid 0 \leq x \leq \frac{\pi}{2}, 0 \leq y \leq \cos x\}$ of the xy -plane about the x -axis.
42. $\pi \int_2^5 y dy = \pi \int_2^5 (\sqrt{y})^2 dy$ describes the volume of the solid obtained by rotating the region $\mathcal{R} = \{(x, y) \mid 2 \leq y \leq 5, 0 \leq x \leq \sqrt{y}\}$ of the xy -plane about the y -axis.
43. $\pi \int_0^1 (y^4 - y^8) dy = \pi \int_0^1 [(y^2)^2 - (y^4)^2] dy$ describes the volume of the solid obtained by rotating the region $\mathcal{R} = \{(x, y) \mid 0 \leq y \leq 1, y^4 \leq x \leq y^2\}$ of the xy -plane about the y -axis.
44. $\pi \int_0^{\pi/2} [(1 + \cos x)^2 - 1^2] dx$ describes the volume of the solid obtained by rotating the region $\mathcal{R} = \{(x, y) \mid 0 \leq x \leq \frac{\pi}{2}, 1 \leq y \leq 1 + \cos x\}$ of the xy -plane about the x -axis.
 Or: The solid could be obtained by rotating the region $\mathcal{R}' = \{(x, y) \mid 0 \leq x \leq \frac{\pi}{2}, 0 \leq y \leq \cos x\}$ about the line $y = -1$.
45. There are 10 subintervals over the 15-cm length, so we'll use $n = 10/2 = 5$ for the Midpoint Rule.
 $V = \int_0^{15} A(x) dx \approx M_5 = \frac{15-0}{5} [A(1.5) + A(4.5) + A(7.5) + A(10.5) + A(13.5)]$
 $= 3(18 + 79 + 106 + 128 + 39) = 3 \cdot 370 = 1110 \text{ cm}^3$

$$\begin{aligned}
 46. V &= \int_0^{10} A(x) dx \approx M_5 = \frac{10-0}{5} [A(1) + A(3) + A(5) + A(7) + A(9)] \\
 &= 2(0.65 + 0.61 + 0.59 + 0.55 + 0.50) = 2(2.90) = 5.80 \text{ m}^3
 \end{aligned}$$

47. We'll form a right circular cone with height h and base radius r by revolving the line $y = \frac{r}{h}x$ about the x -axis.

$$\begin{aligned}
 V &= \pi \int_0^h \left(\frac{r}{h}x\right)^2 dx = \pi \int_0^h \frac{r^2}{h^2} x^2 dx = \pi \frac{r^2}{h^2} \left[\frac{1}{3}x^3\right]_0^h \\
 &= \pi \frac{r^2}{h^2} \left(\frac{1}{3}h^3\right) = \frac{1}{3}\pi r^2 h
 \end{aligned}$$

Another solution: Revolve $x = -\frac{r}{h}y + r$ about the y -axis.

$$\begin{aligned}
 V &= \pi \int_0^h \left(-\frac{r}{h}y + r\right)^2 dy = \pi \int_0^h \left[\frac{r^2}{h^2}y^2 - \frac{2r^2}{h}y + r^2\right] dy \\
 &= \pi \left[\frac{r^2}{3h^2}y^3 - \frac{r^2}{h}y^2 + r^2y\right]_0^h = \pi \left(\frac{1}{3}r^2h - r^2h + r^2h\right) = \frac{1}{3}\pi r^2 h
 \end{aligned}$$

* Or use substitution with $u = r - \frac{r}{h}y$ and $du = -\frac{r}{h}dy$ to get

$$\pi \int_r^0 u^2 \left(-\frac{h}{r} du\right) = -\pi \frac{h}{r} \left[\frac{1}{3}u^3\right]_r^0 = -\pi \frac{h}{r} \left(-\frac{1}{3}r^3\right) = \frac{1}{3}\pi r^2 h.$$

$$\begin{aligned}
 48. V &= \pi \int_0^h \left(R - \frac{R-r}{h}y\right)^2 dy \\
 &= \pi \int_0^h \left[R^2 - \frac{2R(R-r)}{h}y + \left(\frac{R-r}{h}\right)^2 y^2\right] dy \\
 &= \pi \left[R^2y - \frac{R(R-r)}{h}y^2 + \frac{1}{3}\left(\frac{R-r}{h}\right)^2 y^3\right]_0^h \\
 &= \pi \left[R^2h - R(R-r)h + \frac{1}{3}(R-r)^2h\right] \\
 &= \frac{1}{3}\pi h [3Rr + (R^2 - 2Rr + r^2)] = \frac{1}{3}\pi h (R^2 + Rr + r^2)
 \end{aligned}$$

Another solution: $\frac{H}{R} = \frac{H-h}{r}$ by similar triangles. Therefore,

$$Hr = HR - hR \Rightarrow hR = H(R-r) \Rightarrow H = \frac{hR}{R-r}. \text{ Now}$$

$$\begin{aligned}
 V &= \frac{1}{3}\pi R^2 H - \frac{1}{3}\pi r^2 (H-h) \quad [\text{by Exercise 47}] \\
 &= \frac{1}{3}\pi R^2 \frac{hR}{R-r} - \frac{1}{3}\pi r^2 \frac{r h}{R-r} \quad \left[H-h = \frac{rH}{R} = \frac{r h R}{R(R-r)}\right] \\
 &= \frac{1}{3}\pi h \frac{R^3 - r^3}{R-r} = \frac{1}{3}\pi h (R^2 + Rr + r^2) \\
 &= \frac{1}{3} \left[\pi R^2 + \pi r^2 + \sqrt{(\pi R^2)(\pi r^2)}\right] h = \frac{1}{3} (A_1 + A_2 + \sqrt{A_1 A_2}) h
 \end{aligned}$$

where A_1 and A_2 are the areas of the bases of the frustum. (See Exercise 50 for a related result.)

49. $x^2 + y^2 = r^2 \Leftrightarrow x^2 = r^2 - y^2$

$$\begin{aligned}
 V &= \pi \int_{r-h}^r (r^2 - y^2) dy = \pi \left[r^2 y - \frac{y^3}{3} \right]_{r-h}^r \\
 &= \pi \left\{ \left[r^3 - \frac{r^3}{3} \right] - \left[r^2(r-h) - \frac{(r-h)^3}{3} \right] \right\} \\
 &= \pi \left\{ \frac{2}{3} r^3 - \frac{1}{3} (r-h) [3r^2 - (r-h)^2] \right\} \\
 &= \frac{1}{3} \pi \{ 2r^3 - (r-h) [3r^2 - (r^2 - 2rh + h^2)] \} \\
 &= \frac{1}{3} \pi \{ 2r^3 - (r-h) [2r^2 + 2rh - h^2] \} \\
 &= \frac{1}{3} \pi (2r^3 - 2r^3 - 2r^2h + rh^2 + 2r^2h + 2rh^2 - h^3) \\
 &= \frac{1}{3} \pi (3rh^2 - h^3) = \frac{1}{3} \pi h^2 (3r - h), \text{ or, equivalently, } \pi h^2 \left(r - \frac{h}{3} \right)
 \end{aligned}$$

50. An equation of the line is $x = \frac{\Delta x}{\Delta y} y + (x\text{-intercept}) = \frac{a/2 - b/2}{h - 0} y + \frac{b}{2} = \frac{a-b}{2h} y + \frac{b}{2}$.

$$\begin{aligned}
 V &= \int_0^h A(y) dy = \int_0^h (2x)^2 dy \\
 &= \int_0^h \left[2 \left(\frac{a-b}{2h} y + \frac{b}{2} \right) \right]^2 dy = \int_0^h \left[\frac{a-b}{h} y + b \right]^2 dy \\
 &= \int_0^h \left[\frac{(a-b)^2}{h^2} y^2 + \frac{2b(a-b)}{h} y + b^2 \right] dy \\
 &= \left[\frac{(a-b)^2}{3h^2} y^3 + \frac{b(a-b)}{h} y^2 + b^2 y \right]_0^h \\
 &= \frac{1}{3} (a-b)^2 h + b(a-b)h + b^2 h = \frac{1}{3} (a^2 - 2ab + b^2 + 3ab) h \\
 &= \frac{1}{3} (a^2 + ab + b^2) h
 \end{aligned}$$

[Note that this can be written as $\frac{1}{3} (A_1 + A_2 + \sqrt{A_1 A_2}) h$, as in Exercise 48.]

If $a = b$, we get a rectangular solid with volume $b^2 h$. If $a = 0$, we get a square pyramid with volume $\frac{1}{3} b^2 h$.

51. For a cross-section at height y , we see from similar triangles that $\frac{\alpha/2}{b/2} = \frac{h-y}{h}$, so $\alpha = b \left(1 - \frac{y}{h} \right)$.

Similarly, for cross-sections having $2b$ as their base and β replacing α , $\beta = 2b \left(1 - \frac{y}{h} \right)$. So

$$\begin{aligned}
 V &= \int_0^h A(y) dy = \int_0^h \left[b \left(1 - \frac{y}{h} \right) \right] \left[2b \left(1 - \frac{y}{h} \right) \right] dy \\
 &= \int_0^h 2b^2 \left(1 - \frac{y}{h} \right)^2 dy = 2b^2 \int_0^h \left(1 - \frac{2y}{h} + \frac{y^2}{h^2} \right) dy \\
 &= 2b^2 \left[y - \frac{y^2}{h} + \frac{y^3}{3h^2} \right]_0^h = 2b^2 \left[h - h + \frac{1}{3} h \right] \\
 &= \frac{2}{3} b^2 h \quad \left[= \frac{1}{3} B h \text{ where } B \text{ is the area of the base, as with any pyramid.} \right]
 \end{aligned}$$

52. Consider the triangle consisting of two vertices of the base and the center of the base. This triangle is similar to the corresponding triangle at a height y , so $a/b = \alpha/\beta \Rightarrow \alpha = a\beta/b$. Also by similar triangles, $b/h = \beta/(h - y) \Rightarrow \beta = b(h - y)/h$. These two equations imply that $\alpha = a(1 - y/h)$, and since the cross-section is an equilateral triangle, it has area

$$A(y) = \frac{1}{2} \cdot \alpha \cdot \frac{\sqrt{3}}{2} \alpha = \frac{a^2(1 - y/h)^2}{4} \sqrt{3}, \text{ so}$$

$$\begin{aligned} V &= \int_0^h A(y) dy = \frac{a^2 \sqrt{3}}{4} \int_0^h \left(1 - \frac{y}{h}\right)^2 dy \\ &= \frac{a^2 \sqrt{3}}{4} \left[-\frac{h}{3} \left(1 - \frac{y}{h}\right)^3 \right]_0^h = -\frac{\sqrt{3}}{12} a^2 h(-1) = \frac{\sqrt{3}}{12} a^2 h \end{aligned}$$

53. A cross-section at height z is a triangle similar to the base, so we'll multiply the legs of the base triangle, 3 and 4, by a proportionality factor of $(5 - z)/5$. Thus, the triangle at height z has area

$$A(z) = \frac{1}{2} \cdot 3 \left(\frac{5 - z}{5}\right) \cdot 4 \left(\frac{5 - z}{5}\right) = 6 \left(1 - \frac{z}{5}\right)^2, \text{ so}$$

$$\begin{aligned} V &= \int_0^5 A(z) dz = 6 \int_0^5 \left(1 - z/5\right)^2 dz \\ &= 6 \int_1^0 u^2 (-5 du) \quad [u = 1 - z/5, du = -\frac{1}{5} dz] \\ &= -30 \left[\frac{1}{3} u^3 \right]_1^0 = -30 \left(-\frac{1}{3}\right) = 10 \text{ cm}^3 \end{aligned}$$

54. A cross-section is shaded in the diagram.

$$A(x) = (2y)^2 = (2\sqrt{r^2 - x^2})^2, \text{ so}$$

$$\begin{aligned} V &= \int_{-r}^r A(x) dx = 2 \int_0^r 4(r^2 - x^2) dx \\ &= 8 \left[r^2 x - \frac{1}{3} x^3 \right]_0^r \\ &= 8 \left(\frac{2}{3} r^3 \right) = \frac{16}{3} r^3 \end{aligned}$$

55. If l is a leg of the isosceles right triangle and $2y$ is the hypotenuse, then $l^2 + l^2 = (2y)^2 \Rightarrow 2l^2 = 4y^2 \Rightarrow l^2 = 2y^2$.

$$\begin{aligned} V &= \int_{-2}^2 A(x) dx = 2 \int_0^2 A(x) dx = 2 \int_0^2 \frac{1}{2} (l)(l) dx = 2 \int_0^2 y^2 dx \\ &= 2 \int_0^2 \frac{1}{4} (36 - 9x^2) dx = \frac{9}{2} \int_0^2 (4 - x^2) dx \\ &= \frac{9}{2} \left[4x - \frac{1}{3} x^3 \right]_0^2 = \frac{9}{2} \left(8 - \frac{8}{3} \right) = 24 \end{aligned}$$

56. The cross-section of the base corresponding to the coordinate y has length $2x = 2\sqrt{y}$. The corresponding equilateral triangle with side s has area $A(y) = s^2 \left(\frac{\sqrt{3}}{4} \right) = (2x)^2 \left(\frac{\sqrt{3}}{4} \right) = (2\sqrt{y})^2 \left(\frac{\sqrt{3}}{4} \right) = y\sqrt{3}$. Therefore, $V = \int_0^1 A(y) dy = \int_0^1 y\sqrt{3} dy = \sqrt{3} \left[\frac{1}{2}y^2 \right]_0^1 = \frac{\sqrt{3}}{2}$.

57. The cross-section of the base corresponding to the coordinate y has length $2x = 2\sqrt{y}$. The square has area $A(y) = (2\sqrt{y})^2 = 4y$, so $V = \int_0^1 A(y) dy = \int_0^1 4y dy = [2y^2]_0^1 = 2$.

58. A typical cross-section perpendicular to the y -axis in the base has length $\ell(y) = 3 - \frac{3}{2}y$. This length is the diameter of a cross-sectional semicircle in S , so

$$\begin{aligned} V &= \int_0^2 A(y) dy = \int_0^2 \frac{\pi}{2} \left[\frac{\ell(y)}{2} \right]^2 dy = \frac{\pi}{8} \int_0^2 \left(3 - \frac{3}{2}y \right)^2 dy \\ &= \frac{\pi}{8} \int_3^0 u^2 \left(-\frac{2}{3} du \right) \quad \left[u = 3 - \frac{3}{2}y, du = -\frac{3}{2} dy \right] \\ &= -\frac{\pi}{12} \left[\frac{1}{3} u^3 \right]_3^0 = -\frac{\pi}{12} (-9) = \frac{3\pi}{4} \end{aligned}$$

59. A typical cross-section perpendicular to the y -axis in the base has length $\ell(y) = 3 - \frac{3}{2}y$. This length is the leg of an isosceles right triangle, so

$$\begin{aligned} A(y) &= \frac{1}{2} [\ell(y)]^2 \quad \left[\frac{1}{2}bh \text{ with base} = \text{height} \right] \\ &= \frac{1}{2} \left[3 \left(1 - \frac{1}{2}y \right) \right]^2 = \frac{9}{2} \left(1 - \frac{1}{2}y \right)^2 \end{aligned}$$

Thus,

$$\begin{aligned} V &= \int_0^2 A(y) dy = \frac{9}{2} \int_1^0 u^2 (-2 du) \quad \left[u = 1 - \frac{1}{2}y, du = -\frac{1}{2} dy \right] \\ &= -9 \left[\frac{1}{3} u^3 \right]_1^0 = -9 \left(-\frac{1}{3} \right) = 3 \end{aligned}$$

60. (a) $V = \int_{-r}^r A(x) dx = 2 \int_0^r A(x) dx = 2 \int_0^r \frac{1}{2} h (2\sqrt{r^2 - x^2}) dx = 2h \int_0^r \sqrt{r^2 - x^2} dx$

(b) Observe that the integral represents one quarter of the area of a circle of radius r , so $V = 2h \cdot \frac{1}{4} \pi r^2 = \frac{1}{2} \pi h r^2$.

61. (a) The torus is obtained by rotating the circle $(x - R)^2 + y^2 = r^2$ about the y -axis. Solving for x , we see that the right half of the circle is given by $x = R + \sqrt{r^2 - y^2} = f(y)$ and the left half by $x = R - \sqrt{r^2 - y^2} = g(y)$. So

$$\begin{aligned} V &= \pi \int_{-r}^r \{ [f(y)]^2 - [g(y)]^2 \} dy \\ &= 2\pi \int_0^r \left[\left(R^2 + 2R\sqrt{r^2 - y^2} + r^2 - y^2 \right) - \left(R^2 - 2R\sqrt{r^2 - y^2} + r^2 - y^2 \right) \right] dy \\ &= 2\pi \int_0^r 4R\sqrt{r^2 - y^2} dy = 8\pi R \int_0^r \sqrt{r^2 - y^2} dy \end{aligned}$$

- (b) Observe that the integral represents a quarter of the area of a circle with radius r , so

$$8\pi R \int_0^r \sqrt{r^2 - y^2} dy = 8\pi R \cdot \frac{1}{4}\pi r^2 = 2\pi^2 r^2 R.$$

62. The cross-sections perpendicular to the y -axis in Figure 17 are rectangles. The rectangle corresponding to the coordinate y has a base of length $2\sqrt{16 - y^2}$ in the xy -plane and a height of $\frac{1}{\sqrt{3}}y$, since $\angle BAC = 30^\circ$ and $|BC| = \frac{1}{\sqrt{3}}|AB|$. Thus, $A(y) = \frac{2}{\sqrt{3}}y\sqrt{16 - y^2}$ and

$$\begin{aligned} V &= \int_0^4 A(y) dy = \frac{2}{\sqrt{3}} \int_0^4 \sqrt{16 - y^2} y dy \\ &= \frac{2}{\sqrt{3}} \int_{16}^0 u^{1/2} \left(-\frac{1}{2} du\right) \quad [\text{Put } u = 16 - y^2, \text{ so } du = -2y dy] \\ &= \frac{1}{\sqrt{3}} \int_0^{16} u^{1/2} du = \frac{1}{\sqrt{3}} \frac{2}{3} \left[u^{3/2} \right]_0^{16} = \frac{2}{3\sqrt{3}} (64) = \frac{128}{3\sqrt{3}} \end{aligned}$$

63. (a) $\text{Volume}(S_1) = \int_0^h A(z) dz = \text{Volume}(S_2)$ since the cross-sectional area $A(z)$ at height z is the same for both solids.
- (b) By Cavalieri's Principle, the volume of the cylinder in the figure is the same as that of a right circular cylinder with radius r and height h , that is, $\pi r^2 h$.

64. Each cross-section of the solid S in a plane perpendicular to the x -axis is a square (since the edges of the cut lie on the cylinders, which are perpendicular). One-quarter of this square and one-eighth of S are shown. The area of this quarter-square is $|PQ|^2 = r^2 - x^2$. Therefore,

$$A(x) = 4(r^2 - x^2) \text{ and the volume of } S$$

$$\begin{aligned} V &= \int_{-r}^r A(x) dx = 4 \int_{-r}^r (r^2 - x^2) dx \\ &= 8 \int_0^r (r^2 - x^2) dx = 8 \left[r^2 x - \frac{1}{3} x^3 \right]_0^r = \frac{16}{3} r^3 \end{aligned}$$

65. The volume is obtained by rotating the area common to two circles of radius r , as shown. The volume of the right half is

$$\begin{aligned} V_{\text{right}} &= \pi \int_0^{r/2} y^2 dx = \pi \int_0^{r/2} \left[r^2 - \left(\frac{1}{2}r + x \right)^2 \right] dx \\ &= \pi \left[r^2 x - \frac{1}{3} \left(\frac{1}{2}r + x \right)^3 \right]_0^{r/2} = \pi \left[\left(\frac{1}{2}r^3 - \frac{1}{3}r^3 \right) - \left(0 - \frac{1}{24}r^3 \right) \right] = \frac{5}{24}\pi r^3 \end{aligned}$$

So by symmetry, the total volume is twice this, or $\frac{5}{12}\pi r^3$.

Another solution: We observe that the volume is the twice the volume of a cap of a sphere, so we can use the formula from Exercise 49 with $h = \frac{1}{2}r$: $V = 2 \cdot \frac{1}{3}\pi h^2(3r - h) = \frac{2}{3}\pi \left(\frac{1}{2}r\right)^2 \left(3r - \frac{1}{2}r\right) = \frac{5}{12}\pi r^3$.

66. We consider two cases: one in which the ball is not completely submerged and the other in which it is.

Case 1: $0 \leq h \leq 10$ The ball will not be completely submerged, and so a cross-section of the water parallel to the surface will be the shaded area shown in the first diagram. We can find the area of the cross-section at height x above the bottom of the bowl by using the Pythagorean Theorem: $R^2 = 15^2 - (15 - x)^2$ and $r^2 = 5^2 - (x - 5)^2$, so $A(x) = \pi(R^2 - r^2) = 20\pi x$. The volume of water when it has depth h is then

$$V(h) = \int_0^h A(x) dx = \int_0^h 20\pi x dx = [10\pi x^2]_0^h = 10\pi h^2 \text{ cm}^3, 0 \leq h \leq 10.$$

Case 2: $10 < h \leq 15$ In this case we can find the volume by simply subtracting the volume displaced by the ball from the total volume inside the bowl underneath the surface of the water. The total volume underneath the surface is just the volume of a cap of the bowl,

so we use the formula from Exercise 49:

$$V_{\text{cap}}(h) = \frac{1}{3}\pi h^2(45 - h). \text{ The volume of}$$

$$\text{the small sphere is } V_{\text{ball}} = \frac{4}{3}\pi(5)^3 = \frac{500}{3}\pi,$$

so the total volume is

$$V_{\text{cap}} - V_{\text{ball}} = \frac{1}{3}\pi(45h^2 - h^3 - 500) \text{ cm}^3.$$

67. Take the x -axis to be the axis of the cylindrical hole of radius r .

A quarter of the cross-section through y , perpendicular to the y -axis, is the rectangle shown. Using the Pythagorean Theorem twice, we see that the dimensions of this rectangle are

$$x = \sqrt{R^2 - y^2} \text{ and } z = \sqrt{r^2 - y^2}, \text{ so}$$

$$\frac{1}{4}A(y) = xz = \sqrt{r^2 - y^2} \sqrt{R^2 - y^2}, \text{ and}$$

$$V = \int_{-r}^r A(y) dy = \int_{-r}^r 4 \sqrt{r^2 - y^2} \sqrt{R^2 - y^2} dy$$

$$= 8 \int_0^r \sqrt{r^2 - y^2} \sqrt{R^2 - y^2} dy$$

68. The line $y = r$ intersects the semicircle $y = \sqrt{R^2 - x^2}$ when $r = \sqrt{R^2 - x^2} \Rightarrow r^2 = R^2 - x^2 \Rightarrow x^2 = R^2 - r^2 \Rightarrow x = \pm\sqrt{R^2 - r^2}$. Rotating the shaded region about the x -axis gives us

$$\begin{aligned}
 V &= \int_{-\sqrt{R^2-r^2}}^{\sqrt{R^2-r^2}} \pi \left[\left(\sqrt{R^2-x^2} \right)^2 - r^2 \right] dx \\
 &= 2\pi \int_0^{\sqrt{R^2-r^2}} (R^2 - x^2 - r^2) dx \quad [\text{by symmetry}] \\
 &= 2\pi \int_0^{\sqrt{R^2-r^2}} [(R^2 - r^2) - x^2] dx = 2\pi \left[(R^2 - r^2)x - \frac{1}{3}x^3 \right]_0^{\sqrt{R^2-r^2}} \\
 &= 2\pi \left[(R^2 - r^2)^{3/2} - \frac{1}{3}(R^2 - r^2)^{3/2} \right] \\
 &= 2\pi \cdot \frac{2}{3}(R^2 - r^2)^{3/2} = \frac{4\pi}{3}(R^2 - r^2)^{3/2}
 \end{aligned}$$

Our answer makes sense in limiting cases. As $r \rightarrow 0$,

$V \rightarrow \frac{4}{3}\pi R^3$, which is the

volume of the full sphere. As

$r \rightarrow R$, $V \rightarrow 0$, which makes

sense because the hole's radius is approaching that of the sphere.

69. (a) The radius of the barrel is the same at each end by symmetry, since the function $y = R - cx^2$ is even. Since the barrel is obtained by rotating the graph of the function y about the x -axis, this radius is equal to the value of y at $x = \frac{1}{2}h$, which is $R - c(\frac{1}{2}h)^2 = R - d = r$.

- (b) The barrel is symmetric about the y -axis, so its volume is twice the volume of that part of the barrel for $x > 0$.

Also, the barrel is a volume of rotation, so

$$\begin{aligned}
 V &= 2 \int_0^{h/2} \pi y^2 dx = 2\pi \int_0^{h/2} (R - cx^2)^2 dx = 2\pi \left[R^2x - \frac{2}{3}Rcx^3 + \frac{1}{5}c^2x^5 \right]_0^{h/2} \\
 &= 2\pi \left(\frac{1}{2}R^2h - \frac{1}{12}Rch^3 + \frac{1}{160}c^2h^5 \right)
 \end{aligned}$$

Trying to make this look more like the expression we want, we rewrite it as

$$V = \frac{1}{3}\pi h \left[2R^2 + \left(R^2 - \frac{1}{2}Rch^2 + \frac{3}{80}c^2h^4 \right) \right]. \text{ But}$$

$$R^2 - \frac{1}{2}Rch^2 + \frac{3}{80}c^2h^4 = \left(R - \frac{1}{4}ch^2 \right)^2 - \frac{1}{40}c^2h^4 = (R - d)^2 - \frac{2}{5} \left(\frac{1}{4}ch^2 \right)^2 = r^2 - \frac{2}{5}d^2.$$

Substituting this back into V , we see that $V = \frac{1}{3}\pi h \left(2R^2 + r^2 - \frac{2}{5}d^2 \right)$, as required.

70. It suffices to consider the case where $\mathcal{R}$ is bounded by the curves $y = f(x)$ and $y = g(x)$ for $a \leq x \leq b$, where $g(x) \leq f(x)$ for all x in $[a, b]$, since other regions can be decomposed into subregions of this type. We are concerned with the volume obtained when $\mathcal{R}$ is rotated about the line $y = -k$, which is equal to

$$\begin{aligned} V_2 &= \pi \int_a^b ([f(x) + k]^2 - [g(x) + k]^2) dx = \pi \int_a^b ([f(x)]^2 - [g(x)]^2) dx + 2\pi k \int_a^b [f(x) - g(x)] dx \\ &= V_1 + 2\pi k A \end{aligned}$$

6.3 Volumes by Cylindrical Shells

1.

If we were to use the “washer” method, we would first have to locate the local maximum point (a, b) of $y = x(x-1)^2$ using the methods of Chapter 4. Then we would have to solve the equation $y = x(x-1)^2$ for x in terms of y to obtain the functions $x = g_1(y)$ and $x = g_2(y)$ shown in the first figure. This step would be difficult because it involves the cubic formula. Finally we would find the volume using

$$V = \pi \int_0^b \{ [g_1(y)]^2 - [g_2(y)]^2 \} dy.$$

Using shells, we find that a typical approximating shell has radius x , so its circumference is $2\pi x$. Its height is y , that is, $x(x-1)^2$. So the total volume is

$$V = \int_0^1 2\pi x [x(x-1)^2] dx = 2\pi \int_0^1 (x^4 - 2x^3 + x^2) dx = 2\pi \left[\frac{x^5}{5} - 2\frac{x^4}{4} + \frac{x^3}{3} \right]_0^1 = \frac{\pi}{15}$$

2.

A typical cylindrical shell has circumference $2\pi x$ and height

$\sin(x^2)$. $V = \int_0^{\sqrt{\pi}} 2\pi x \sin(x^2) dx$. Let $u = x^2$. Then $du = 2x dx$, so $V = \pi \int_0^{\pi} \sin u du = \pi [-\cos u]_0^{\pi} = \pi [1 - (-1)] = 2\pi$.

For slicing, we would first have to locate the local maximum point (a, b) of $y = \sin(x^2)$ using the methods of Chapter 4. Then we would have to solve the equation $y = \sin(x^2)$ for x in terms of y to obtain the functions $x = g_1(y)$ and $x = g_2(y)$ shown in the second figure. Finally we would find the volume using

$V = \pi \int_0^b \{ [g_1(y)]^2 - [g_2(y)]^2 \} dy$. Using shells is definitely preferable to slicing.

$$\begin{aligned} 3. V &= \int_1^2 2\pi x \cdot \frac{1}{x} dx = 2\pi \int_1^2 1 dx \\ &= 2\pi [x]_1^2 = 2\pi(2-1) = 2\pi \end{aligned}$$

$$\begin{aligned}
 4. \quad V &= \int_0^1 2\pi x \cdot x^2 dx = 2\pi \int_0^1 x^3 dx \\
 &= 2\pi \left[\frac{1}{4} x^4 \right]_0^1 = 2\pi \cdot \frac{1}{4} = \frac{\pi}{2}
 \end{aligned}$$

$$\begin{aligned}
 5. \quad V &= \int_0^2 2\pi x (4 - x^2) dx = 2\pi \int_0^2 (4x - x^3) dx \\
 &= 2\pi \left[2x^2 - \frac{1}{4} x^4 \right]_0^2 = 2\pi (8 - 4) \\
 &= 8\pi
 \end{aligned}$$

$$\begin{aligned}
 6. \quad V &= 2\pi \int_0^3 \{x[(3 + 2x - x^2) - (3 - x)]\} dx = 2\pi \int_0^3 [x(3x - x^2)] dx \\
 &= 2\pi \int_0^3 (3x^2 - x^3) dx = 2\pi \left[x^3 - \frac{1}{4} x^4 \right]_0^3 = 2\pi \left(27 - \frac{81}{4} \right) = 2\pi \left(\frac{27}{4} \right) = \frac{27\pi}{2}
 \end{aligned}$$

7. The curves intersect when $4(x - 2)^2 = x^2 - 4x + 7 \Leftrightarrow 4x^2 - 16x + 16 = x^2 - 4x + 7 \Leftrightarrow 3x^2 - 12x + 9 = 0 \Leftrightarrow 3(x^2 - 4x + 3) = 0 \Leftrightarrow 3(x - 1)(x - 3) = 0$, so $x = 1$ or 3 .

$$\begin{aligned}
 V &= 2\pi \int_1^3 \{x[(x^2 - 4x + 7) - 4(x - 2)^2]\} dx = 2\pi \int_1^3 [x(x^2 - 4x + 7 - 4x^2 + 16x - 16)] dx \\
 &= 2\pi \int_1^3 [x(-3x^2 + 12x - 9)] dx = 2\pi(-3) \int_1^3 (x^3 - 4x^2 + 3x) dx = -6\pi \left[\frac{1}{4} x^4 - \frac{4}{3} x^3 + \frac{3}{2} x^2 \right]_1^3 \\
 &= -6\pi \left[\left(\frac{81}{4} - 36 + \frac{27}{2} \right) - \left(\frac{1}{4} - \frac{4}{3} + \frac{3}{2} \right) \right] = -6\pi \left(20 - 36 + 12 + \frac{4}{3} \right) = -6\pi \left(-\frac{8}{3} \right) = 16\pi
 \end{aligned}$$

8. By slicing:

$$V = \int_0^1 \pi \left[(\sqrt{y})^2 - (y^2)^2 \right] dy = \pi \int_0^1 (y - y^4) dy = \pi \left[\frac{1}{2} y^2 - \frac{1}{5} y^5 \right]_0^1 = \pi \left(\frac{1}{2} - \frac{1}{5} \right) = \frac{3\pi}{10}$$

By cylindrical shells:

$$\begin{aligned} V &= \int_0^1 2\pi x (\sqrt{x} - x^2) dx = 2\pi \int_0^1 (x^{3/2} - x^3) dx \\ &= 2\pi \left[\frac{2}{5} x^{5/2} - \frac{1}{4} x^4 \right]_0^1 = 2\pi \left(\frac{2}{5} - \frac{1}{4} \right) \\ &= 2\pi \left(\frac{3}{20} \right) = \frac{3\pi}{10} \end{aligned}$$

$$\begin{aligned} 9. V &= \int_1^2 2\pi y (1 + y^2) dy = 2\pi \int_1^2 (y + y^3) dy = 2\pi \left[\frac{1}{2} y^2 + \frac{1}{4} y^4 \right]_1^2 \\ &= 2\pi \left[(2 + 4) - \left(\frac{1}{2} + \frac{1}{4} \right) \right] = 2\pi \left(\frac{21}{4} \right) = \frac{21\pi}{2} \end{aligned}$$

$$\begin{aligned} 10. V &= \int_0^1 2\pi y \sqrt{y} dy = 2\pi \int_0^1 y^{3/2} dy \\ &= 2\pi \left[\frac{2}{5} y^{5/2} \right]_0^1 = \frac{4\pi}{5} \end{aligned}$$

$$\begin{aligned}
 11. V &= 2\pi \int_0^8 [y(\sqrt[3]{y} - 0)] dy \\
 &= 2\pi \int_0^8 y^{4/3} dy = 2\pi \left[\frac{3}{7} y^{7/3} \right]_0^8 \\
 &= \frac{6\pi}{7} (8^{7/3}) = \frac{6\pi}{7} (2^7) = \frac{768\pi}{7}
 \end{aligned}$$

$$\begin{aligned}
 12. V &= 2\pi \int_0^4 [y(4y^2 - y^3)] dy \\
 &= 2\pi \int_0^4 (4y^3 - y^4) dy \\
 &= 2\pi \left[y^4 - \frac{1}{5} y^5 \right]_0^4 = 2\pi \left(256 - \frac{1024}{5} \right) \\
 &= 2\pi \left(\frac{256}{5} \right) = \frac{512\pi}{5}
 \end{aligned}$$

13. The curves intersect when $4x^2 = 6 - 2x \Leftrightarrow 2x^2 + x - 3 = 0 \Leftrightarrow (2x + 3)(x - 1) = 0 \Leftrightarrow x = -\frac{3}{2}$ or 1 .

Solving the equations for x gives us $y = 4x^2 \Rightarrow x = \pm \frac{1}{2}\sqrt{y}$ and $2x + y = 6 \Rightarrow x = -\frac{1}{2}y + 3$.

$$\begin{aligned}
 V &= 2\pi \int_0^4 \left\{ y \left[\left(\frac{1}{2}\sqrt{y} \right) - \left(-\frac{1}{2}\sqrt{y} \right) \right] \right\} dy + 2\pi \int_4^9 \left\{ y \left[\left(-\frac{1}{2}y + 3 \right) - \left(-\frac{1}{2}\sqrt{y} \right) \right] \right\} dy \\
 &= 2\pi \int_0^4 (y\sqrt{y}) dy + 2\pi \int_4^9 \left(-\frac{1}{2}y^2 + 3y + \frac{1}{2}y^{3/2} \right) dy = 2\pi \left[\frac{2}{5}y^{5/2} \right]_0^4 + 2\pi \left[-\frac{1}{6}y^3 + \frac{3}{2}y^2 + \frac{1}{5}y^{5/2} \right]_4^9 \\
 &= 2\pi \left(\frac{2}{5} \cdot 32 \right) + 2\pi \left[\left(-\frac{243}{2} + \frac{243}{2} + \frac{243}{5} \right) - \left(-\frac{32}{3} + 24 + \frac{32}{5} \right) \right] \\
 &= \frac{128}{5}\pi + 2\pi \left(\frac{433}{15} \right) = \frac{1250}{15}\pi = \frac{250}{3}\pi
 \end{aligned}$$

$$\begin{aligned}
 14. V &= \int_0^3 2\pi y [4 - (y-1)^2 - (3-y)] dy \\
 &= 2\pi \int_0^3 y(-y^2 + 3y) dy \\
 &= 2\pi \int_0^3 (-y^3 + 3y^2) dy = 2\pi \left[-\frac{1}{4}y^4 + y^3 \right]_0^3 \\
 &= 2\pi \left(-\frac{81}{4} + 27 \right) = 2\pi \left(\frac{27}{4} \right) = \frac{27\pi}{2}
 \end{aligned}$$

$$\begin{aligned}
 15. V &= \int_1^2 2\pi(x-1)x^2 dx = 2\pi \left[\frac{1}{4}x^4 - \frac{1}{3}x^3 \right]_1^2 \\
 &= 2\pi \left[\left(4 - \frac{8}{3} \right) - \left(\frac{1}{4} - \frac{1}{3} \right) \right] = \frac{17}{6}\pi
 \end{aligned}$$

$$\begin{aligned}
 16. V &= \int_{-2}^{-1} 2\pi(-x) \cdot x^2 dx = 2\pi \left[-\frac{1}{4}x^4 \right]_{-2}^{-1} \\
 &= 2\pi \left[\left(-\frac{1}{4} \right) - (-4) \right] = \frac{15}{2}\pi
 \end{aligned}$$

$$\begin{aligned}
 17. V &= \int_1^2 2\pi(4-x)x^2 dx = 2\pi \left[\frac{4}{3}x^3 - \frac{1}{4}x^4 \right]_1^2 \\
 &= 2\pi \left[\left(\frac{32}{3} - 4 \right) - \left(\frac{4}{3} - \frac{1}{4} \right) \right] = \frac{67}{6}\pi
 \end{aligned}$$

$$\begin{aligned}
 18. V &= \int_0^4 2\pi[x - (-2)][(8x - 2x^2) - (4x - x^2)] dx \\
 &= \int_0^4 2\pi(2+x)(4x - x^2) dx \\
 &= 2\pi \int_0^4 (8x + 2x^2 - x^3) dx \\
 &= 2\pi \left[4x^2 + \frac{2}{3}x^3 - \frac{1}{4}x^4 \right]_0^4 \\
 &= 2\pi \left(64 + \frac{128}{3} - 64 \right) = \frac{256}{3}\pi
 \end{aligned}$$

$$\begin{aligned}
 19. V &= \int_0^2 2\pi(3-y)(5-x) dy \\
 &= \int_0^2 2\pi(3-y)(5-y^2-1) dy \\
 &= \int_0^2 2\pi(12-4y-3y^2+y^3) dy \\
 &= 2\pi \left[12y - 2y^2 - y^3 + \frac{1}{4}y^4 \right]_0^2 \\
 &= 2\pi(24 - 8 - 8 + 4) = 24\pi
 \end{aligned}$$

$$\begin{aligned}
 20. V &= \int_0^1 2\pi(y+1)(\sqrt{y}-y^2) dy = 2\pi \int_0^1 (y^{3/2} + y^{1/2} - y^3 - y^2) dy \\
 &= 2\pi \left[\frac{2}{5}y^{5/2} + \frac{2}{3}y^{3/2} - \frac{1}{4}y^4 - \frac{1}{3}y^3 \right]_0^1 = 2\pi \left(\frac{2}{5} + \frac{2}{3} - \frac{1}{4} - \frac{1}{3} \right) = 2\pi \left(\frac{29}{60} \right) = \frac{29\pi}{30}
 \end{aligned}$$

$$21. V = \int_{2\pi}^{3\pi} 2\pi x \sin x \, dx$$

$$22. V = \int_0^3 2\pi(7-x)[(4x-x^2)-x] \, dx$$

$$23. V = \int_0^1 2\pi[x - (-1)](\sin \frac{\pi}{2}x - x^4) \, dx$$

$$24. V = \int_0^2 2\pi(2-x) \left(\frac{1}{1+x^2} \right) \, dx$$

25. $V = \int_0^\pi 2\pi(4-y)\sqrt{\sin y} dy$

26. $V = \int_{-3}^3 2\pi(5-y)(4 - \sqrt{y^2 + 7}) dy$

27. $\Delta x = \frac{\pi/4 - 0}{4} = \frac{\pi}{16}$

$V = \int_0^{\pi/4} 2\pi x \tan x dx \approx 2\pi \cdot \frac{\pi}{16} \left(\frac{\pi}{32} \tan \frac{\pi}{32} + \frac{3\pi}{32} \tan \frac{3\pi}{32} + \frac{5\pi}{32} \tan \frac{5\pi}{32} + \frac{7\pi}{32} \tan \frac{7\pi}{32} \right) \approx 1.142$

28. $\Delta x = \frac{12-2}{5} = 2$, $n = 5$ and $x_i^* = 2 + (2i + 1)$, where $i = 0, 1, 2, 3, 4$. The values of $f(x)$ are taken directly from the diagram.

$$V = \int_2^{12} 2\pi x f(x) dx \approx 2\pi[3f(3) + 5f(5) + 7f(7) + 9f(9) + 11f(11)] \cdot 2$$

$$\approx 2\pi[3(2) + 5(4) + 7(4) + 9(2) + 11(1)]2 = 332\pi$$

29. $\int_0^3 2\pi x^5 dx = 2\pi \int_0^3 x(x^4) dx$. The solid is obtained by rotating the region $0 \leq y \leq x^4$, $0 \leq x \leq 3$ about the y-axis using cylindrical shells.

30. $2\pi \int_0^2 \frac{y}{1+y^2} dy = 2\pi \int_0^2 y \left(\frac{1}{1+y^2} \right) dy$. The solid is obtained by rotating the region $0 \leq x \leq \frac{1}{1+y^2}$, $0 \leq y \leq 2$ about the x-axis using cylindrical shells.

31. $\int_0^1 2\pi(3-y)(1-y^2) dy$. The solid is obtained by rotating the region bounded by (i) $x = 1 - y^2$, $x = 0$, and $y = 0$ or (ii) $x = y^2$, $x = 1$, and $y = 0$ about the line $y = 3$ using cylindrical shells.

32. $\int_0^{\pi/4} 2\pi(\pi - x)(\cos x - \sin x) dx$. The solid is obtained by rotating the region bounded by (i) $0 \leq y \leq \cos x - \sin x$, $0 \leq x \leq \frac{\pi}{4}$ or (ii) $\sin x \leq y \leq \cos x$, $0 \leq x \leq \frac{\pi}{4}$ about the line $x = \pi$ using cylindrical shells.

From the graph, the curves intersect at $x = 0$ and at $x = a \approx 1.32$, with $x + x^2 - x^4 > 0$ on the interval $(0, a)$. So the volume of the solid obtained by rotating the region about the y-axis is

$$V = 2\pi \int_0^a [x(x + x^2 - x^4)] dx = 2\pi \int_0^a (x^2 + x^3 - x^5) dx$$

$$= 2\pi \left[\frac{1}{3}x^3 + \frac{1}{4}x^4 - \frac{1}{6}x^6 \right]_0^a \approx 4.05$$

From the graph, the curves intersect at $x = 0$ and at $x = a \approx 1.17$, with $3x - x^3 > x^4$ on the interval $(0, a)$. So the volume of the solid obtained by rotating the region about the y -axis is

$$\begin{aligned} V &= 2\pi \int_0^a \{x[(3x - x^3) - x^4]\} dx = 2\pi \int_0^a (3x^2 - x^4 - x^5) dx \\ &= 2\pi \left[x^3 - \frac{1}{5}x^5 - \frac{1}{6}x^6 \right]_0^a \approx 4.62 \end{aligned}$$

35. $V = 2\pi \int_0^{\pi/2} \left[\left(\frac{\pi}{2} - x \right) (\sin^2 x - \sin^4 x) \right] dx$

$\stackrel{\text{CAS}}{=} \frac{1}{32}\pi^3$

36. $V = 2\pi \int_0^{\pi} \{ [x - (-1)](x^3 \sin x) \} dx \stackrel{\text{CAS}}{=} 2\pi(\pi^4 + \pi^3 - 12\pi^2 - 6\pi + 48)$

$$= 2\pi^5 + 2\pi^4 - 24\pi^3 - 12\pi^2 + 96\pi$$

37. Use disks:

$$\begin{aligned} V &= \int_{-2}^1 \pi(x^2 + x - 2)^2 dx = \pi \int_{-2}^1 (x^4 + 2x^3 - 3x^2 - 4x + 4) dx \\ &= \pi \left[\frac{1}{5}x^5 + \frac{1}{2}x^4 - x^3 - 2x^2 + 4x \right]_{-2}^1 = \pi \left[\left(\frac{1}{5} + \frac{1}{2} - 1 - 2 + 4 \right) - \left(-\frac{32}{5} + 8 + 8 - 8 - 8 \right) \right] \\ &= \pi \left(\frac{33}{5} + \frac{3}{2} \right) = \frac{81}{10}\pi \end{aligned}$$

38. Use shells:

$$\begin{aligned} V &= \int_1^2 2\pi x(-x^2 + 3x - 2) dx = 2\pi \int_1^2 (-x^3 + 3x^2 - 2x) dx \\ &= 2\pi \left[-\frac{1}{4}x^4 + x^3 - x^2 \right]_1^2 = 2\pi \left[(-4 + 8 - 4) - \left(-\frac{1}{4} + 1 - 1 \right) \right] = \frac{\pi}{2} \end{aligned}$$

39. Use shells:

$$\begin{aligned}
 V &= \int_1^4 2\pi [x - (-1)] [5 - (x^2 - 5x + 9)] dx \\
 &= 2\pi \int_1^4 (x+1)(-x^2 + 5x - 4) dx \\
 &= 2\pi \int_1^4 (-x^3 + 4x^2 + x - 4) dx = 2\pi \left[-\frac{1}{4}x^4 + \frac{4}{3}x^3 + \frac{1}{2}x^2 - 4x \right]_1^4 \\
 &= 2\pi \left[\left(-64 + \frac{256}{3} + 8 - 16 \right) - \left(-\frac{1}{4} + \frac{4}{3} + \frac{1}{2} - 4 \right) \right] \\
 &= 2\pi \left(\frac{63}{4} \right) = \frac{63\pi}{2}
 \end{aligned}$$

40. Use washers:

$$\begin{aligned}
 V &= \int_{-1}^1 \pi \left\{ [2 - 0]^2 - [2 - (1 - y^4)]^2 \right\} dy \\
 &= 2\pi \int_0^1 [4 - (1 + y^4)^2] dy \quad [\text{by symmetry}] \\
 &= 2\pi \int_0^1 [4 - (1 + 2y^4 + y^8)] dy = 2\pi \int_0^1 (3 - 2y^4 - y^8) dy \\
 &= 2\pi \left[3y - \frac{2}{5}y^5 - \frac{1}{9}y^9 \right]_0^1 = 2\pi \left(3 - \frac{2}{5} - \frac{1}{9} \right) = 2\pi \left(\frac{112}{45} \right) = \frac{224\pi}{45}
 \end{aligned}$$

41. Use disks: $V = \pi \int_0^2 \left[\sqrt{1 - (y-1)^2} \right]^2 dy = \pi \int_0^2 (2y - y^2) dy = \pi \left[y^2 - \frac{1}{3}y^3 \right]_0^2 = \pi \left(4 - \frac{8}{3} \right) = \frac{4}{3}\pi$

42. Using shells, we have

$$\begin{aligned}
 V &= \int_0^2 2\pi y \left[\sqrt{1 - (y-1)^2} - \left(-\sqrt{1 - (y-1)^2} \right) \right] dy \\
 &= 2\pi \int_0^2 y \cdot 2\sqrt{1 - (y-1)^2} dy = 4\pi \int_{-1}^1 (u+1)\sqrt{1-u^2} du \quad [\text{let } u = y-1] \\
 &= 4\pi \int_{-1}^1 u\sqrt{1-u^2} du + 4\pi \int_{-1}^1 \sqrt{1-u^2} du
 \end{aligned}$$

The first definite integral equals zero because its integrand is an odd function. The second is the area of a semicircle of radius 1, that is, $\frac{\pi}{2}$. Thus, $V = 4\pi \cdot 0 + 4\pi \cdot \frac{\pi}{2} = 2\pi^2$.

43. $V = 2 \int_0^r 2\pi x \sqrt{r^2 - x^2} dx = -2\pi \int_0^r (r^2 - x^2)^{1/2} (-2x) dx = \left[-2\pi \cdot \frac{2}{3} (r^2 - x^2)^{3/2} \right]_0^r$
 $= -\frac{4}{3}\pi(0 - r^3) = \frac{4}{3}\pi r^3$

44. $V = \int_{-r}^{R+r} 2\pi x \cdot 2\sqrt{r^2 - (x-R)^2} dx$
 $= \int_{-r}^r 4\pi(u+R)\sqrt{r^2 - u^2} du \quad [\text{let } u = x-R]$
 $= 4\pi R \int_{-r}^r \sqrt{r^2 - u^2} du + 4\pi \int_{-r}^r u\sqrt{r^2 - u^2} du$

The first integral is the area of a semicircle of radius r , that is, $\frac{1}{2}\pi r^2$, and the second is zero since the integrand is an odd function. Thus,
 $V = 4\pi R \left(\frac{1}{2}\pi r^2 \right) + 4\pi \cdot 0 = 2\pi R r^2$.

$$45. V = 2\pi \int_0^r x \left(-\frac{h}{r}x + h \right) dx = 2\pi h \int_0^r \left(-\frac{x^2}{r} + x \right) dx = 2\pi h \left[-\frac{x^3}{3r} + \frac{x^2}{2} \right]_0^r = 2\pi h \frac{r^2}{6} = \frac{\pi r^2 h}{3}$$

46. By symmetry, the volume of a napkin ring obtained by drilling a hole of radius r through a sphere with radius R is twice the volume obtained by rotating the area above the x -axis and below the curve $y = \sqrt{R^2 - x^2}$ (the equation of the top half of the cross-section of the sphere), between $x = r$ and $x = R$, about the y -axis.

This volume is equal to

$$2 \int_{\text{inner radius}}^{\text{outer radius}} 2\pi r h \, dx = 2 \cdot 2\pi \int_r^R x \sqrt{R^2 - x^2} \, dx = 4\pi \left[-\frac{1}{3} (R^2 - x^2)^{3/2} \right]_r^R = \frac{4}{3}\pi (R^2 - r^2)^{3/2}$$

But by the Pythagorean Theorem, $R^2 - r^2 = (\frac{1}{2}h)^2$, so the volume of the napkin ring is $\frac{4}{3}\pi (\frac{1}{2}h)^3 = \frac{1}{6}\pi h^3$, which is independent of both R and r ; that is, the amount of wood in a napkin ring of height h is the same regardless of the size of the sphere used. Note that most of this calculation has been done already, but with more difficulty, in Exercise 6.2.68.

Another solution: The height of the missing cap is the radius of the sphere minus half the height of the cut-out cylinder, that is, $R - \frac{1}{2}h$. Using Exercise 6.2.49,

$$V_{\text{napkin ring}} = V_{\text{sphere}} - V_{\text{cylinder}} - 2V_{\text{cap}} = \frac{4}{3}\pi R^3 - \pi r^2 h - 2 \cdot \frac{\pi}{3} (R - \frac{1}{2}h)^2 [3R - (R - \frac{1}{2}h)] = \frac{1}{6}\pi h^3$$

6.4 Work

- By Equation 2, $W = Fd = (900)(8) = 7200$ J.
- $F = mg = (60)(9.8) = 588$ N; $W = Fd = 588 \cdot 2 = 1176$ J
- $W = \int_a^b f(x) \, dx = \int_0^9 \frac{10}{(1+x)^2} \, dx = 10 \int_1^{10} \frac{1}{u^2} \, du \quad [u = 1+x, \, du = dx]$
 $= 10 \left[-\frac{1}{u} \right]_1^{10} = 10 \left(-\frac{1}{10} + 1 \right) = 9$ ft-lb
- $W = \int_1^2 \cos\left(\frac{1}{3}\pi x\right) \, dx = \frac{3}{\pi} \left[\sin\left(\frac{1}{3}\pi x\right) \right]_1^2 = \frac{3}{\pi} \left(\frac{\sqrt{3}}{2} - \frac{\sqrt{3}}{2} \right) = 0$ N-m = 0 J.

Interpretation: From $x = 1$ to $x = \frac{3}{2}$, the force does work equal to $\int_1^{3/2} \cos\left(\frac{1}{3}\pi x\right) \, dx = \frac{3}{\pi} \left(1 - \frac{\sqrt{3}}{2} \right)$ J in accelerating the particle and increasing its kinetic energy. From $x = \frac{3}{2}$ to $x = 2$, the force opposes the motion of the particle, decreasing its kinetic energy. This is negative work, equal in magnitude but opposite in sign to the work done from $x = 1$ to $x = \frac{3}{2}$.

- The force function is given by $F(x)$ (in newtons) and the work (in joules) is the area under the curve, given by $\int_0^8 F(x) \, dx = \int_0^4 F(x) \, dx + \int_4^8 F(x) \, dx = \frac{1}{2}(4)(30) + (4)(30) = 180$ J.
- $W = \int_4^{20} f(x) \, dx \approx M_4 = \Delta x [f(6) + f(10) + f(14) + f(18)] = \frac{20-4}{4} [5.8 + 8.8 + 8.2 + 5.2] = 4(28) = 112$ J
- $10 = f(x) = kx = \frac{1}{3}k$ [4 inches = $\frac{1}{3}$ foot], so $k = 30$ lb/ft and $f(x) = 30x$. Now 6 inches = $\frac{1}{2}$ foot, so $W = \int_0^{1/2} 30x \, dx = \left[15x^2 \right]_0^{1/2} = \frac{15}{4}$ ft-lb.

8. $25 = f(x) = kx = k(0.1)$ [10 cm = 0.1 m], so $k = 250$ N/m and $f(x) = 250x$. Now 5 cm = 0.05 m, so

$$W = \int_0^{0.05} 250x \, dx = [125x^2]_0^{0.05} = 125(0.0025) = 0.3125 \approx 0.31 \text{ J.}$$

9. If $\int_0^{0.12} kx \, dx = 2$ J, then $2 = [\frac{1}{2}kx^2]_0^{0.12} = \frac{1}{2}k(0.0144) = 0.0072k$ and $k = \frac{2}{0.0072} = \frac{2500}{9} \approx 277.78$ N/m.

Thus, the work needed to stretch the spring from 35 cm to 40 cm is

$$\int_{0.05}^{0.10} \frac{2500}{9} x \, dx = [\frac{1250}{9} x^2]_{1/20}^{1/10} = \frac{1250}{9} (\frac{1}{100} - \frac{1}{400}) = \frac{25}{24} \approx 1.04 \text{ J.}$$

10. If $12 = \int_0^1 kx \, dx = [\frac{1}{2}kx^2]_0^1 = \frac{1}{2}k$, then $k = 24$ lb/ft and the work required is

$$\int_0^{3/4} 24x \, dx = [12x^2]_0^{3/4} = 12 \cdot \frac{9}{16} = \frac{27}{4} = 6.75 \text{ ft-lb.}$$

11. $f(x) = kx$, so $30 = \frac{2500}{9}x$ and $x = \frac{270}{2500}$ m = 10.8 cm

12. Let L be the natural length of the spring in meters. Then

$$6 = \int_{0.10-L}^{0.12-L} kx \, dx = [\frac{1}{2}kx^2]_{0.10-L}^{0.12-L} = \frac{1}{2}k[(0.12-L)^2 - (0.10-L)^2] \text{ and}$$

$$10 = \int_{0.12-L}^{0.14-L} kx \, dx = [\frac{1}{2}kx^2]_{0.12-L}^{0.14-L} = \frac{1}{2}k[(0.14-L)^2 - (0.12-L)^2]. \text{ Simplifying gives us}$$

$$12 = k(0.0044 - 0.04L) \text{ and } 20 = k(0.0052 - 0.04L). \text{ Subtracting the first equation from the second gives}$$

$$8 = 0.0008k, \text{ so } k = 10,000. \text{ Now the second equation becomes } 20 = 52 - 400L, \text{ so } L = \frac{32}{400} \text{ m} = 8 \text{ cm.}$$

In Exercises 13–20, n is the number of subintervals of length Δx , and x_i^* is a sample point in the i th subinterval $[x_{i-1}, x_i]$.

13. (a) The portion of the rope from x ft to $(x + \Delta x)$ ft below the top of the building weighs $\frac{1}{2} \Delta x$ lb and must be lifted x_i^* ft, so its contribution to the total work is $\frac{1}{2} x_i^* \Delta x$ ft-lb. The total work is

$$W = \lim_{n \rightarrow \infty} \sum_{i=1}^n \frac{1}{2} x_i^* \Delta x = \int_0^{50} \frac{1}{2} x \, dx = [\frac{1}{4} x^2]_0^{50} = \frac{2500}{4} = 625 \text{ ft-lb}$$

Notice that the exact height of the building does not matter (as long as it is more than 50 ft).

(b) When half the rope is pulled to the top of the building, the work to lift the top half of the rope is

$$W_1 = \int_0^{25} \frac{1}{2} x \, dx = [\frac{1}{4} x^2]_0^{25} = \frac{625}{4} \text{ ft-lb. The bottom half of the rope is lifted 25 ft and the work needed to}$$

$$\text{accomplish that is } W_2 = \int_{25}^{50} \frac{1}{2} \cdot 25 \, dx = \frac{25}{2} [x]_{25}^{50} = \frac{625}{2} \text{ ft-lb. The total work done in pulling half the rope to the top of the building is } W = W_1 + W_2 = \frac{625}{2} + \frac{625}{4} = \frac{3}{4} \cdot 625 = \frac{1875}{4} \text{ ft-lb.}$$

14. Assumptions: 1. After lifting, the chain is L-shaped, with 4 m of the chain lying along the ground.

2. The chain slides effortlessly and without friction along the ground while its end is lifted.

3. The weight density of the chain is constant throughout its length and therefore equals

$$(8 \text{ kg/m})(9.8 \text{ m/s}^2) = 78.4 \text{ N/m.}$$

The part of the chain x m from the lifted end is raised $6 - x$ m if $0 \leq x \leq 6$ m, and it is lifted 0 m if $x > 6$ m.

Thus, the work needed is

$$W = \lim_{n \rightarrow \infty} \sum_{i=1}^n (6 - x_i^*) \cdot 78.4 \Delta x = \int_0^6 (6 - x) 78.4 \, dx = 78.4 [6x - \frac{1}{2} x^2]_0^6 = (78.4)(18) = 1411.2 \text{ J.}$$

15. The work needed to lift the cable is $\lim_{n \rightarrow \infty} \sum_{i=1}^n 2x_i^* \Delta x = \int_0^{500} 2x \, dx = [x^2]_0^{500} = 250,000$ ft-lb. The work needed to lift the coal is $800 \text{ lb} \cdot 500 \text{ ft} = 400,000$ ft-lb. Thus, the total work required is $250,000 + 400,000 = 650,000$ ft-lb.

16. The work needed to lift the bucket itself is $4 \text{ lb} \cdot 80 \text{ ft} = 320 \text{ ft-lb}$. At time t (in seconds) the bucket is $x_i^* = 2t$ ft above its original 80 ft depth, but it now holds only $(40 - 0.2t)$ lb of water. In terms of distance, the bucket holds $[40 - 0.2(\frac{1}{2}x_i^*)]$ lb of water when it is x_i^* ft above its original 80 ft depth. Moving this amount of water a distance Δx requires $(40 - \frac{1}{10}x_i^*) \Delta x$ ft-lb of work. Thus, the work needed to lift the water is

$$W = \lim_{n \rightarrow \infty} \sum_{i=1}^n (40 - \frac{1}{10}x_i^*) \Delta x = \int_0^{80} (40 - \frac{1}{10}x) dx = [40x - \frac{1}{20}x^2]_0^{80} = (3200 - 320) \text{ ft-lb}$$

Adding the work of lifting the bucket gives a total of 3200 ft-lb of work.

17. At a height of x meters ($0 \leq x \leq 12$), the mass of the rope is $(0.8 \text{ kg/m})(12 - x \text{ m}) = (9.6 - 0.8x) \text{ kg}$ and the mass of the water is $(\frac{36}{12} \text{ kg/m})(12 - x \text{ m}) = (36 - 3x) \text{ kg}$. The mass of the bucket is 10 kg, so the total mass is $(9.6 - 0.8x) + (36 - 3x) + 10 = (55.6 - 3.8x) \text{ kg}$, and hence, the total force is $9.8(55.6 - 3.8x) \text{ N}$.

The work needed to lift the bucket Δx m through the i th subinterval of $[0, 12]$ is $9.8(55.6 - 3.8x_i^*) \Delta x$, so the total work is

$$\begin{aligned} W &= \lim_{n \rightarrow \infty} \sum_{i=1}^n 9.8(55.6 - 3.8x_i^*) \Delta x = \int_0^{12} (9.8)(55.6 - 3.8x) dx = 9.8 \left[55.6x - 1.9x^2 \right]_0^{12} \\ &= 9.8(393.6) \approx 3857 \text{ J} \end{aligned}$$

18. The chain's weight density is $\frac{25 \text{ lb}}{10 \text{ ft}} = 2.5 \text{ lb/ft}$. The part of the chain x ft below the ceiling (for $5 \leq x \leq 10$) has to be lifted $2(x - 5)$ ft, so the work needed to lift the i th subinterval of the chain is $2(x_i^* - 5)(2.5 \Delta x)$. The total work needed is

$$\begin{aligned} W &= \lim_{n \rightarrow \infty} \sum_{i=1}^n 2(x_i^* - 5)(2.5) \Delta x = \int_5^{10} [2(x - 5)(2.5)] dx = 5 \int_5^{10} (x - 5) dx \\ &= 5 \left[\frac{1}{2}x^2 - 5x \right]_5^{10} = 5 \left[(50 - 50) - \left(\frac{25}{2} - 25 \right) \right] = 5 \left(\frac{25}{2} \right) = 62.5 \text{ ft-lb} \end{aligned}$$

19. A "slice" of water Δx m thick and lying at a depth of x_i^* m (where $0 \leq x_i^* \leq \frac{1}{2}$) has volume $(2 \times 1 \times \Delta x) \text{ m}^3$, a mass of $2000 \Delta x$ kg, weighs about $(9.8)(2000 \Delta x) = 19,600 \Delta x \text{ N}$, and thus requires about $19,600x_i^* \Delta x$ J of work for its removal. So $W = \lim_{n \rightarrow \infty} \sum_{i=1}^n 19,600x_i^* \Delta x = \int_0^{1/2} 19,600x dx = [9800x^2]_0^{1/2} = 2450 \text{ J}$.
20. A horizontal cylindrical slice of water Δx ft thick has a volume of $\pi r^2 h = \pi \cdot 12^2 \cdot \Delta x \text{ ft}^3$ and weighs about $(62.5 \text{ lb/ft}^3)(144\pi \Delta x \text{ ft}^3) = 9000\pi \Delta x \text{ lb}$. If the slice lies x_i^* ft below the edge of the pool (where $1 \leq x_i^* \leq 5$), then the work needed to pump it out is about $9000\pi x_i^* \Delta x$. Thus,

$$W = \lim_{n \rightarrow \infty} \sum_{i=1}^n 9000\pi x_i^* \Delta x = \int_1^5 9000\pi x dx = [4500\pi x^2]_1^5 = 4500\pi(25 - 1) = 108,000\pi \text{ ft-lb}$$

21. A rectangular "slice" of water Δx m thick and lying x ft above the bottom has width x ft and volume $8x \Delta x \text{ m}^3$. It weighs about $(9.8 \times 1000)(8x \Delta x) \text{ N}$, and must be lifted $(5 - x) \text{ m}$ by the pump, so the work needed is about $(9.8 \times 10^3)(5 - x)(8x \Delta x) \text{ J}$. The total work required is

$$\begin{aligned} W &\approx \int_0^3 (9.8 \times 10^3)(5 - x)8x dx = (9.8 \times 10^3) \int_0^3 (40x - 8x^2) dx = (9.8 \times 10^3) \left[20x^2 - \frac{8}{3}x^3 \right]_0^3 \\ &= (9.8 \times 10^3)(180 - 72) = (9.8 \times 10^3)(108) = 1058.4 \times 10^3 \approx 1.06 \times 10^6 \text{ J} \end{aligned}$$

22. For convenience, measure depth x from the middle of the tank, so that $-1.5 \leq x \leq 1.5$ m.

Lifting a slice of water of thickness Δx at depth x requires a work contribution of

$$\Delta W \approx (9.8 \times 10^3) \left(2\sqrt{(1.5)^2 - x^2} \right) (6 \Delta x)(2.5 + x), \text{ so}$$

$$\begin{aligned} W &\approx \int_{-1.5}^{1.5} (9.8 \times 10^3) 12 \sqrt{2.25 - x^2} (2.5 + x) dx \\ &= (9.8 \times 10^3) \left[60 \int_0^{3/2} \sqrt{\frac{9}{4} - x^2} dx + 12 \int_{-3/2}^{3/2} x \sqrt{\frac{9}{4} - x^2} dx \right] \end{aligned}$$

The second integral is 0 because its integrand is an odd function, and the first integral represents the area of a quarter-circle of radius $\frac{3}{2}$. Therefore,

$$W \approx (9.8 \times 10^3) 60 \int_0^{3/2} \sqrt{\frac{9}{4} - x^2} dx = (9.8 \times 10^3) (60) \left(\frac{1}{4} \pi \right) \left(\frac{3}{2} \right)^2 = 330,750\pi \approx 1.04 \times 10^6 \text{ J}$$

23. Measure depth x downward from the flat top of the tank, so that $0 \leq x \leq 2$ ft. Then

$$\Delta W = (62.5)(2\sqrt{4 - x^2})(8 \Delta x)(x + 1) \text{ ft-lb, so}$$

$$\begin{aligned} W &\approx (62.5)(16) \int_0^2 (x + 1) \sqrt{4 - x^2} dx = 1000 \left(\int_0^2 x \sqrt{4 - x^2} dx + \int_0^2 \sqrt{4 - x^2} dx \right) \\ &= 1000 \left[\int_0^4 u^{1/2} \left(\frac{1}{2} du \right) + \frac{1}{4} \pi (2^2) \right] \quad [\text{Put } u = 4 - x^2, \text{ so } du = -2x dx] \\ &= 1000 \left(\left[\frac{1}{2} \cdot \frac{2}{3} u^{3/2} \right]_0^4 + \pi \right) = 1000 \left(\frac{8}{3} + \pi \right) \approx 5.8 \times 10^3 \text{ ft-lb} \end{aligned}$$

Note: The second integral represents the area of a quarter-circle of radius 2.

24. Let x be depth in feet, so that $0 \leq x \leq 5$. Then $\Delta W = (62.5)\pi(\sqrt{5^2 - x^2})^2 \Delta x \cdot x$ ft-lb and

$$\begin{aligned} W &\approx 62.5\pi \int_0^5 x(25 - x^2) dx = 62.5\pi \left[\frac{25}{2} x^2 - \frac{1}{4} x^4 \right]_0^5 = 62.5\pi \left(\frac{625}{2} - \frac{625}{4} \right) = 62.5\pi \left(\frac{625}{4} \right) \\ &\approx 3.07 \times 10^4 \text{ ft-lb} \end{aligned}$$

25. If only 4.7×10^5 J of work is done, then only the water above a certain level (call it h) will be pumped out. So we use the same formula as in Exercise 21, except that the work is fixed, and we are trying to find the lower limit of

$$\text{integration: } 4.7 \times 10^5 \approx \int_h^3 (9.8 \times 10^3)(5 - x)8x dx = (9.8 \times 10^3) \left[20x^2 - \frac{8}{3}x^3 \right]_h^3 \Leftrightarrow$$

$$\frac{4.7}{9.8} \times 10^2 \approx 48 = \left(20 \cdot 3^2 - \frac{8}{3} \cdot 3^3 \right) - \left(20h^2 - \frac{8}{3}h^3 \right) \Leftrightarrow$$

$$2h^3 - 15h^2 + 45 = 0. \text{ To find the solution of this equation, we plot}$$

$$2h^3 - 15h^2 + 45 \text{ between } h = 0 \text{ and } h = 3. \text{ We see that the equation}$$

is satisfied for $h \approx 2.0$. So the depth of water remaining in the tank is about 2.0 m.

$$26. W \approx (9.8 \times 920) \int_0^{3/2} 12 \sqrt{\frac{9}{4} - x^2} \left(\frac{5}{2} + x\right) dx = 9016 \left[30 \int_0^{3/2} \sqrt{\frac{9}{4} - x^2} dx + 12 \int_0^{3/2} x \sqrt{\frac{9}{4} - x^2} dx \right].$$

$$\text{Here } \int_0^{3/2} \sqrt{\frac{9}{4} - x^2} dx = \frac{1}{4} \pi \left(\frac{3}{2}\right)^2 = \frac{9\pi}{16} \text{ and } \int_0^{3/2} x \sqrt{\frac{9}{4} - x^2} dx = \int_0^{9/4} \frac{1}{2} u^{1/2} du$$

$$[\text{where } u = \frac{9}{4} - x^2, \text{ so } du = -2x dx] = \left[-\frac{1}{3} u^{3/2} \right]_0^{9/4} = -\frac{1}{3} \left(\frac{27}{8} \right) = -\frac{9}{8}, \text{ so}$$

$$W \approx 9016 \left[30 \cdot \frac{9\pi}{16} + 12 \cdot \frac{9}{8} \right] = 9016 \left(\frac{135}{8} \pi + \frac{27}{2} \right) \approx 6.00 \times 10^5 \text{ J.}$$

27. $V = \pi r^2 x$, so V is a function of x and P can also be regarded as a function of x . If $V_1 = \pi r^2 x_1$ and $V_2 = \pi r^2 x_2$, then

$$\begin{aligned} W &= \int_{x_1}^{x_2} F(x) dx = \int_{x_1}^{x_2} \pi r^2 P(V(x)) dx \\ &= \int_{x_1}^{x_2} P(V(x)) dV(x) \quad [\text{Let } V(x) = \pi r^2 x, \text{ so } dV(x) = \pi r^2 dx.] \\ &= \int_{V_1}^{V_2} P(V) dV \quad \text{by the Substitution Rule.} \end{aligned}$$

$$28. 160 \text{ lb/in}^2 = 160 \cdot 144 \text{ lb/ft}^2, 100 \text{ in}^3 = \frac{100}{1728} \text{ ft}^3, \text{ and } 800 \text{ in}^3 = \frac{800}{1728} \text{ ft}^3.$$

$$k = PV^{1.4} = (160 \cdot 144) \left(\frac{100}{1728} \right)^{1.4} = 23,040 \left(\frac{25}{432} \right)^{1.4} \approx 426.5. \text{ Therefore, } P \approx 426.5 V^{-1.4} \text{ and}$$

$$\begin{aligned} W &= \int_{100/1728}^{800/1728} 426.5 V^{-1.4} dV = 426.5 \left[\frac{-1}{-0.4} V^{-0.4} \right]_{25/432}^{25/54} \\ &= (426.5)(2.5) \left[\left(\frac{432}{25} \right)^{0.4} - \left(\frac{54}{25} \right)^{0.4} \right] \\ &\approx 1.88 \times 10^3 \text{ ft-lb} \end{aligned}$$

$$29. W = \int_a^b F(r) dr = \int_a^b G \frac{m_1 m_2}{r^2} dr = G m_1 m_2 \left[\frac{-1}{r} \right]_a^b = G m_1 m_2 \left(\frac{1}{a} - \frac{1}{b} \right)$$

30. By Exercise 29, $W = GMm \left(\frac{1}{R} - \frac{1}{R + 1,000,000} \right)$ where M = mass of Earth in kg, R = radius of Earth in m, and m = mass of satellite in kg. (Note that 1000 km = 1,000,000 m.) Thus,

$$W = (6.67 \times 10^{-11}) (5.98 \times 10^{24}) (1000) \times \left(\frac{1}{6.37 \times 10^6} - \frac{1}{7.37 \times 10^6} \right) \approx 8.50 \times 10^9 \text{ J}$$

6.5 Average Value of a Function

$$1. f_{\text{ave}} = \frac{1}{b-a} \int_a^b f(x) dx = \frac{1}{1-(-1)} \int_{-1}^1 x^2 dx = \frac{1}{2} \cdot 2 \int_0^1 x^2 dx = \left[\frac{1}{3} x^3 \right]_0^1 = \frac{1}{3}$$

$$2. f_{\text{ave}} = \frac{1}{2-0} \int_0^2 (x-x^2) dx = \frac{1}{2} \left[\frac{1}{2} x^2 - \frac{1}{3} x^3 \right]_0^2 = \frac{1}{2} \left(2 - \frac{8}{3} \right) = -\frac{1}{3}$$

$$3. g_{\text{ave}} = \frac{1}{\frac{\pi}{2} - 0} \int_0^{\pi/2} \cos x \, dx = \frac{2}{\pi} [\sin x]_0^{\pi/2} = \frac{2}{\pi} (1 - 0) = \frac{2}{\pi}$$

$$4. g_{\text{ave}} = \frac{1}{2-0} \int_0^2 x^2 \sqrt{1+x^3} \, dx = \frac{1}{2} \int_1^9 \sqrt{u} \cdot \frac{1}{3} \, du \quad [u = 1+x^3, du = 3x^2 \, dx]$$

$$= \frac{1}{6} \left[\frac{2}{3} u^{3/2} \right]_1^9 = \frac{1}{9} (27 - 1) = \frac{26}{9}$$

$$5. f_{\text{ave}} = \frac{1}{5-0} \int_0^5 t \sqrt{1+t^2} \, dt = \frac{1}{5} \int_1^{26} \sqrt{u} \left(\frac{1}{2} \, du \right) \quad [u = 1+t^2, du = 2t \, dt]$$

$$= \frac{1}{10} \int_1^{26} u^{1/2} \, du = \frac{1}{10} \cdot \frac{2}{3} \left[u^{3/2} \right]_1^{26} = \frac{1}{15} (26^{3/2} - 1)$$

$$6. f_{\text{ave}} = \frac{1}{\frac{\pi}{4} - 0} \int_0^{\pi/4} \sec \theta \tan \theta \, d\theta = \frac{4}{\pi} [\sec \theta]_0^{\pi/4} = \frac{4}{\pi} (\sqrt{2} - 1)$$

$$7. h_{\text{ave}} = \frac{1}{\pi - 0} \int_0^{\pi} \cos^4 x \sin x \, dx = \frac{1}{\pi} \int_1^{-1} u^4 (-du) \quad [u = \cos x, du = -\sin x \, dx]$$

$$= \frac{1}{\pi} \int_{-1}^1 u^4 \, du = \frac{1}{\pi} \cdot 2 \int_0^1 u^4 \, du = \frac{2}{\pi} \left[\frac{1}{5} u^5 \right]_0^1 = \frac{2}{5\pi}$$

$$8. h_{\text{ave}} = \frac{1}{6-1} \int_1^6 \frac{3}{(1+r)^2} \, dr = \frac{1}{5} \int_2^7 3u^{-2} \, du \quad [u = 1+r, du = dr]$$

$$= -\frac{3}{5} [u^{-1}]_2^7 = -\frac{3}{5} \left(\frac{1}{7} - \frac{1}{2} \right) = \frac{3}{5} \left(\frac{1}{2} - \frac{1}{7} \right) = \frac{3}{5} \cdot \frac{5}{14} = \frac{3}{14}$$

$$9. (a) f_{\text{ave}} = \frac{1}{5-2} \int_2^5 (x-3)^2 \, dx = \frac{1}{3} \left[\frac{1}{3} (x-3)^3 \right]_2^5$$

$$= \frac{1}{9} [2^3 - (-1)^3] = \frac{1}{9} (8 + 1) = 1$$

$$(b) f(c) = f_{\text{ave}} \Leftrightarrow (c-3)^2 = 1 \Leftrightarrow c-3 = \pm 1$$

$$\Leftrightarrow c = 2 \text{ or } 4$$

$$10. (a) f_{\text{ave}} = \frac{1}{4-0} \int_0^4 \sqrt{x} \, dx = \frac{1}{4} \left[\frac{2}{3} x^{3/2} \right]_0^4$$

$$= \frac{1}{6} [x^{3/2}]_0^4 = \frac{1}{6} [8 - 0] = \frac{4}{3}$$

$$(b) f(c) = f_{\text{ave}} \Leftrightarrow \sqrt{c} = \frac{4}{3} \Leftrightarrow c = \frac{16}{9}$$

$$11. (a) f_{\text{ave}} = \frac{1}{\pi - 0} \int_0^{\pi} (2 \sin x - \sin 2x) \, dx$$

$$= \frac{1}{\pi} \left[-2 \cos x + \frac{1}{2} \cos 2x \right]_0^{\pi}$$

$$= \frac{1}{\pi} \left[\left(2 + \frac{1}{2} \right) - \left(-2 + \frac{1}{2} \right) \right] = \frac{4}{\pi}$$

$$(b) f(c) = f_{\text{ave}} \Leftrightarrow 2 \sin c - \sin 2c = \frac{4}{\pi} \Leftrightarrow$$

$$c_1 \approx 1.238 \text{ or } c_2 \approx 2.808$$

$$\begin{aligned}
 12. (a) f_{\text{ave}} &= \frac{1}{2-0} \int_0^2 \frac{2x}{(1+x^2)^2} dx \\
 &= \frac{1}{2} \int_1^5 \frac{1}{u^2} du \quad [u = 1+x^2, du = 2x dx] \\
 &= \frac{1}{2} \left[-\frac{1}{u} \right]_1^5 = -\frac{1}{2} \left(\frac{1}{5} - 1 \right) = \frac{2}{5}
 \end{aligned}$$

$$\begin{aligned}
 (b) f(c) = f_{\text{ave}} &\Leftrightarrow \frac{2c}{(1+c^2)^2} = \frac{2}{5} \Leftrightarrow 5c = (1+c^2)^2 \\
 &\Leftrightarrow c_1 \approx 0.220 \text{ or } c_2 \approx 1.207
 \end{aligned}$$

13. f is continuous on $[1, 3]$, so by the Mean Value Theorem for Integrals there exists a number c in $[1, 3]$ such that $\int_1^3 f(x) dx = f(c)(3-1) \Rightarrow 8 = 2f(c)$; that is, there is a number c such that $f(c) = \frac{8}{2} = 4$.

14. The requirement is that $\frac{1}{b-0} \int_0^b f(x) dx = 3$. The LHS of this equation is equal to

$$\begin{aligned}
 \frac{1}{b} \int_0^b (2+6x-3x^2) dx &= \frac{1}{b} [2x+3x^2-x^3]_0^b = 2+3b-b^2, \text{ so we solve the equation } 2+3b-b^2=3 \Leftrightarrow \\
 b^2-3b+1 &= 0 \Leftrightarrow b = \frac{3 \pm \sqrt{(-3)^2-4 \cdot 1 \cdot 1}}{2 \cdot 1} = \frac{3 \pm \sqrt{5}}{2}. \text{ Both roots are valid since they are positive.}
 \end{aligned}$$

$$\begin{aligned}
 15. f_{\text{ave}} &= \frac{1}{50-20} \int_{20}^{50} f(x) dx \approx \frac{1}{30} M_3 = \frac{1}{30} \cdot \frac{50-20}{3} [f(25) + f(35) + f(45)] \\
 &= \frac{1}{3} (38 + 29 + 48) = \frac{115}{3} = 38\frac{1}{3}
 \end{aligned}$$

$$\begin{aligned}
 16. (a) v_{\text{ave}} &= \frac{1}{12-0} \int_0^{12} v(t) dt = \frac{1}{12} I. \text{ Use the Midpoint Rule with } n=3 \text{ and } \Delta t = \frac{12-0}{3} = 4 \text{ to estimate } I. \\
 I &\approx M_3 = 4[v(2) + v(6) + v(10)] = 4[21 + 50 + 66] = 4(137) = 548. \text{ Thus, } v_{\text{ave}} \approx \frac{1}{12}(548) = 45\frac{2}{3} \text{ km/h.}
 \end{aligned}$$

$$(b) \text{ Estimating from the graph, } v(t) = 45\frac{2}{3} \text{ when } t \approx 5.2 \text{ s.}$$

17. Let $t = 0$ and $t = 12$ correspond to 9 A.M. and 9 P.M., respectively.

$$\begin{aligned}
 T_{\text{ave}} &= \frac{1}{12-0} \int_0^{12} \left[50 + 14 \sin \frac{1}{12} \pi t \right] dt = \frac{1}{12} \left[50t - 14 \cdot \frac{12}{\pi} \cos \frac{1}{12} \pi t \right]_0^{12} \\
 &= \frac{1}{12} \left[50 \cdot 12 + 14 \cdot \frac{12}{\pi} + 14 \cdot \frac{12}{\pi} \right] = \left(50 + \frac{28}{\pi} \right) ^\circ \text{F} \approx 59^\circ \text{F}
 \end{aligned}$$

$$18. T_{\text{ave}} = \frac{1}{5} \int_0^5 4x dx = \frac{1}{5} [2x^2]_0^5 = 10^\circ \text{C}$$

$$19. \rho_{\text{ave}} = \frac{1}{8} \int_0^8 \frac{12}{\sqrt{x+1}} dx = \frac{3}{2} \int_0^8 (x+1)^{-1/2} dx = [3\sqrt{x+1}]_0^8 = 9 - 3 = 6 \text{ kg/m}$$

$$\begin{aligned}
 20. s &= \frac{1}{2}gt^2 \Rightarrow t = \sqrt{2s/g} \quad [\text{since } t \geq 0]. \text{ Now } v = \frac{ds}{dt} = gt = g\sqrt{2s/g} = \sqrt{2gs} \Rightarrow v^2 = 2gs \Rightarrow \\
 s &= \frac{v^2}{2g}. \text{ We see that } v \text{ can be regarded as a function of } t \text{ or of } s: v = F(t) = gt \text{ and } v = G(s) = \sqrt{2gs}. \text{ Note that} \\
 v_T &= F(T) = gT. \text{ Displacement can be viewed as a function of } t: s = s(t) = \frac{1}{2}gt^2; \text{ also } s(t) = \frac{v^2}{2g} = \frac{[F(t)]^2}{2g}.
 \end{aligned}$$

When $t = T$, these two formulas for $s(t)$ imply that

$$\sqrt{2gs(T)} = F(T) = v_T = gT = 2\left(\frac{1}{2}gT^2\right)/T = 2s(T)/T \quad (*)$$

The average of the velocities with respect to time t during the interval $[0, T]$ is

$$\begin{aligned} v_{t\text{-ave}} = F_{\text{ave}} &= \frac{1}{T-0} \int_0^T F(t) dt = \frac{1}{T} [s(T) - s(0)] \quad [\text{by FTC}] \\ &= \frac{s(T)}{T} \quad [\text{since } s(0) = 0] = \frac{1}{2}v_T \quad [\text{by } (*)] \end{aligned}$$

But the average of the velocities with respect to displacement s during the corresponding displacement interval $[s(0), s(T)] = [0, s(T)]$ is

$$\begin{aligned} v_{s\text{-ave}} = G_{\text{ave}} &= \frac{1}{s(T)-0} \int_0^{s(T)} G(s) ds = \frac{1}{s(T)} \int_0^{s(T)} \sqrt{2gs} ds = \frac{\sqrt{2g}}{s(T)} \int_0^{s(T)} s^{1/2} ds \\ &= \frac{\sqrt{2g}}{s(T)} \cdot \frac{2}{3} [s^{3/2}]_0^{s(T)} = \frac{2}{3} \cdot \frac{\sqrt{2g}}{s(T)} \cdot [s(T)]^{3/2} = \frac{2}{3} \sqrt{2gs(T)} = \frac{2}{3}v_T \quad [\text{by } (*)] \end{aligned}$$

$$\begin{aligned} 21. V_{\text{ave}} &= \frac{1}{5} \int_0^5 V(t) dt = \frac{1}{5} \int_0^5 \frac{5}{4\pi} [1 - \cos(\frac{2}{5}\pi t)] dt = \frac{1}{4\pi} \int_0^5 [1 - \cos(\frac{2}{5}\pi t)] dt \\ &= \frac{1}{4\pi} [t - \frac{5}{2\pi} \sin(\frac{2}{5}\pi t)]_0^5 = \frac{1}{4\pi} [(5-0) - 0] = \frac{5}{4\pi} \approx 0.4 \text{ L} \end{aligned}$$

$$22. v_{\text{ave}} = \frac{1}{R-0} \int_0^R v(r) dr = \frac{1}{R} \int_0^R \frac{P}{4\eta l} (R^2 - r^2) dr = \frac{P}{4\eta l R} [R^2 r - \frac{1}{3}r^3]_0^R = \frac{P}{4\eta l R} (\frac{2}{3})R^3 = \frac{PR^2}{6\eta l}.$$

Since $v(r)$ is decreasing on $(0, R]$, $v_{\text{max}} = v(0) = \frac{PR^2}{4\eta l}$. Thus, $v_{\text{ave}} = \frac{2}{3}v_{\text{max}}$.

23. Let $F(x) = \int_a^x f(t) dt$ for x in $[a, b]$. Then F is continuous on $[a, b]$ and differentiable on (a, b) , so by the Mean Value Theorem there is a number c in (a, b) such that $F(b) - F(a) = F'(c)(b-a)$. But $F'(x) = f(x)$ by the Fundamental Theorem of Calculus. Therefore, $\int_a^b f(t) dt - 0 = f(c)(b-a)$.

$$\begin{aligned} 24. f_{\text{ave}} [a, b] &= \frac{1}{b-a} \int_a^b f(x) dx = \frac{1}{b-a} \int_a^c f(x) dx + \frac{1}{b-a} \int_c^b f(x) dx \\ &= \frac{c-a}{b-a} \left[\frac{1}{c-a} \int_a^c f(x) dx \right] + \frac{b-c}{b-a} \left[\frac{1}{b-c} \int_c^b f(x) dx \right] = \frac{c-a}{b-a} f_{\text{ave}} [a, c] + \frac{b-c}{b-a} f_{\text{ave}} [c, b] \end{aligned}$$

6 Review

CONCEPT CHECK

- (a) See Section 6.1, Figure 2 and Equations 6.1.1 and 6.1.2.
(b) Instead of using “top minus bottom” and integrating from left to right, we use “right minus left” and integrate from bottom to top. See Figures 11 and 12 in Section 6.1.
- The numerical value of the area represents the number of meters by which Sue is ahead of Kathy after 1 minute.

3. (a) See the discussion in Section 6.2, near Figures 2 and 3, ending in the Definition of Volume.
- (b) See the discussion between Examples 5 and 6 in Section 6.2. If the cross-section is a disk, find the radius in terms of x or y and use $A = \pi(\text{radius})^2$. If the cross-section is a washer, find the inner radius r_{in} and outer radius r_{out} and use $A = \pi(r_{\text{out}}^2) - \pi(r_{\text{in}}^2)$.
4. (a) $V = 2\pi rh \Delta r = (\text{circumference})(\text{height})(\text{thickness})$
- (b) For a typical shell, find the circumference and height in terms of x or y and calculate $V = \int_a^b (\text{circumference})(\text{height})(dx \text{ or } dy)$, where a and b are the limits on x or y .
- (c) Sometimes slicing produces washers or disks whose radii are difficult (or impossible) to find explicitly. On other occasions, the cylindrical shell method leads to an easier integral than slicing does.
5. $\int_0^6 f(x) dx$ represents the amount of work done. Its units are newton-meters, or joules.
6. (a) The average value of a function f on an interval $[a, b]$ is $f_{\text{ave}} = \frac{1}{b-a} \int_a^b f(x) dx$.
- (b) The Mean Value Theorem for Integrals says that there is a number c at which the value of f is exactly equal to the average value of the function, that is, $f(c) = f_{\text{ave}}$. For a geometric interpretation of the Mean Value Theorem for Integrals, see Figure 2 in Section 6.5 and the discussion that accompanies it.

EXERCISES

1. $0 = x^2 - x - 6 = (x-3)(x+2) \Leftrightarrow x = 3 \text{ or } -2$. So

$$\begin{aligned} A &= \int_{-2}^3 [0 - (x^2 - x - 6)] dx = \int_{-2}^3 (-x^2 + x + 6) dx \\ &= \left[-\frac{1}{3}x^3 + \frac{1}{2}x^2 + 6x\right]_{-2}^3 \\ &= \left(-9 + \frac{9}{2} + 18\right) - \left(\frac{8}{3} + 2 - 12\right) \\ &= \frac{125}{6} \end{aligned}$$

2. $20 - x^2 = x^2 - 12 \Leftrightarrow 32 = 2x^2 \Leftrightarrow x^2 = 16 \Leftrightarrow x = \pm 4$.
So

$$\begin{aligned} A &= \int_{-4}^4 [(20 - x^2) - (x^2 - 12)] dx = \int_{-4}^4 (32 - 2x^2) dx \\ &= 2 \int_0^4 (32 - 2x^2) dx \quad [\text{even function}] \\ &= 2 \left[32x - \frac{2}{3}x^3 \right]_0^4 \\ &= 2 \left(128 - \frac{128}{3} \right) = \frac{512}{3} \end{aligned}$$

$$\begin{aligned}
 3. \quad 1 - x^2 &= 1 - \sqrt{x} \Leftrightarrow -x^2 = -\sqrt{x} \Leftrightarrow x^2 = \sqrt{x} \Rightarrow x^4 = x \\
 &\Rightarrow x^4 - x = 0 \Rightarrow x(x^3 - 1) = 0 \Rightarrow \\
 x(x-1)(x^2+x+1) &= 0 \Rightarrow x = 0 \text{ or } 1. \text{ So}
 \end{aligned}$$

$$\begin{aligned}
 A &= \int_0^1 [(1-x^2) - (1-\sqrt{x})] dx = \int_0^1 (\sqrt{x} - x^2) dx \\
 &= \left[\frac{2}{3}x^{3/2} - \frac{1}{3}x^3 \right]_0^1 = \frac{2}{3} - \frac{1}{3} = \frac{1}{3}
 \end{aligned}$$

$$\begin{aligned}
 4. \quad y^2 + 3y &= -y \Leftrightarrow y^2 + 4y = 0 \Leftrightarrow y(y+4) = 0 \Leftrightarrow \\
 y &= 0 \text{ or } -4.
 \end{aligned}$$

$$\begin{aligned}
 A &= \int_{-4}^0 [-y - (y^2 + 3y)] dy = \int_{-4}^0 (-y^2 - 4y) dy \\
 &= \left[-\frac{1}{3}y^3 - 2y^2 \right]_{-4}^0 = 0 - \left(\frac{64}{3} - 32 \right) = \frac{32}{3}
 \end{aligned}$$

$$\begin{aligned}
 5. \quad A &= \int_0^2 \left[\sin\left(\frac{\pi x}{2}\right) - (x^2 - 2x) \right] dx \\
 &= \left[-\frac{2}{\pi} \cos\left(\frac{\pi x}{2}\right) - \frac{1}{3}x^3 + x^2 \right]_0^2 \\
 &= \left(\frac{2}{\pi} - \frac{8}{3} + 4 \right) - \left(-\frac{2}{\pi} - 0 + 0 \right) = \frac{4}{3} + \frac{4}{\pi}
 \end{aligned}$$

$$\begin{aligned}
 6. \quad A &= \int_0^1 (\sqrt{x} - x^2) dx + \int_1^2 (x^2 - \sqrt{x}) dx \\
 &= \left[\frac{2}{3}x^{3/2} - \frac{1}{3}x^3 \right]_0^1 + \left[\frac{1}{3}x^3 - \frac{2}{3}x^{3/2} \right]_1^2 \\
 &= \left[\left(\frac{2}{3} - \frac{1}{3} \right) - 0 \right] + \left[\left(\frac{8}{3} - \frac{4}{3}\sqrt{2} \right) - \left(\frac{1}{3} - \frac{2}{3} \right) \right] \\
 &= \frac{10}{3} - \frac{4}{3}\sqrt{2}
 \end{aligned}$$

7. Using washers with inner radius x^2 and outer radius $2x$, we have

$$\begin{aligned}
 V &= \pi \int_0^2 [(2x)^2 - (x^2)^2] dx = \pi \int_0^2 (4x^2 - x^4) dx \\
 &= \pi \left[\frac{4}{3}x^3 - \frac{1}{5}x^5 \right]_0^2 = \pi \left(\frac{32}{3} - \frac{32}{5} \right) = 32\pi \cdot \frac{2}{15} \\
 &= \frac{64\pi}{15}
 \end{aligned}$$

$$8. 1 + y^2 = y + 3 \Leftrightarrow y^2 - y - 2 = 0 \Leftrightarrow (y - 2)(y + 1) = 0 \Leftrightarrow y = 2 \text{ or } -1.$$

$$\begin{aligned} V &= \pi \int_{-1}^2 [(y + 3)^2 - (1 + y^2)^2] dy \\ &= \pi \int_{-1}^2 (y^2 + 6y + 9 - 1 - 2y^2 - y^4) dy \\ &= \pi \int_{-1}^2 (8 + 6y - y^2 - y^4) dy = \pi \left[8y + 3y^2 - \frac{1}{3}y^3 - \frac{1}{5}y^5 \right]_{-1}^2 \\ &= \pi \left[\left(16 + 12 - \frac{8}{3} - \frac{32}{5} \right) - \left(-8 + 3 + \frac{1}{3} + \frac{1}{5} \right) \right] \\ &= \pi \left(33 - \frac{9}{3} - \frac{33}{5} \right) = \frac{117\pi}{5} \end{aligned}$$

$$\begin{aligned} 9. V &= \pi \int_{-3}^3 \left\{ [(9 - y^2) - (-1)]^2 - [0 - (-1)]^2 \right\} dy \\ &= 2\pi \int_0^3 [(10 - y^2)^2 - 1] dy \\ &= 2\pi \int_0^3 (100 - 20y^2 + y^4 - 1) dy \\ &= 2\pi \int_0^3 (99 - 20y^2 + y^4) dy = 2\pi \left[99y - \frac{20}{3}y^3 + \frac{1}{5}y^5 \right]_0^3 \\ &= 2\pi \left(297 - 180 + \frac{243}{5} \right) = \frac{1656\pi}{5} \end{aligned}$$

$$\begin{aligned} 10. V &= \pi \int_{-2}^2 \left\{ [(9 - x^2) - (-1)]^2 - [(x^2 + 1) - (-1)]^2 \right\} dx \\ &= \pi \int_{-2}^2 [(10 - x^2)^2 - (x^2 + 2)^2] dx \\ &= 2\pi \int_0^2 (96 - 24x^2) dx = 48\pi \int_0^2 (4 - x^2) dx \\ &= 48\pi \left[4x - \frac{1}{3}x^3 \right]_0^2 = 48\pi \left(8 - \frac{8}{3} \right) = 256\pi \end{aligned}$$

11. The graph of $x^2 - y^2 = a^2$ is a hyperbola with right and left branches. Solving for y gives us $y^2 = x^2 - a^2 \Rightarrow y = \pm\sqrt{x^2 - a^2}$. We'll use shells and the height of each shell is $\sqrt{x^2 - a^2} - (-\sqrt{x^2 - a^2}) = 2\sqrt{x^2 - a^2}$.

The volume is $V = \int_a^{a+h} 2\pi x \cdot 2\sqrt{x^2 - a^2} dx$. To evaluate, let $u = x^2 - a^2$, so $du = 2x dx$ and $x dx = \frac{1}{2} du$.

When $x = a$, $u = 0$, and when $x = a + h$,

$$u = (a + h)^2 - a^2 = a^2 + 2ah + h^2 - a^2 = 2ah + h^2.$$

$$\text{Thus, } V = 4\pi \int_0^{2ah+h^2} \sqrt{u} \left(\frac{1}{2} du \right) = 2\pi \left[\frac{2}{3} u^{3/2} \right]_0^{2ah+h^2} = \frac{4}{3}\pi (2ah + h^2)^{3/2}.$$

12. $V = \int_{3\pi/2}^{5\pi/2} 2\pi x \cos x \, dx$ [by the method of cylindrical shells]

13. $V = \int_0^1 \pi \left[(1-x^3)^2 - (1-x^2)^2 \right] dx$

14. $V = \int_0^2 2\pi(8-x^3)(2-x) \, dx$

15. (a) A cross-section is a washer with inner radius x^2 and outer radius x .

$$V = \int_0^1 \pi \left[(x)^2 - (x^2)^2 \right] dx = \int_0^1 \pi (x^2 - x^4) \, dx = \pi \left[\frac{1}{3}x^3 - \frac{1}{5}x^5 \right]_0^1 = \pi \left[\frac{1}{3} - \frac{1}{5} \right] = \frac{2\pi}{15}$$

- (b) A cross-section is a washer with inner radius y and outer radius $\sqrt{y}$.

$$V = \int_0^1 \pi \left[(\sqrt{y})^2 - y^2 \right] dy = \int_0^1 \pi (y - y^2) \, dy = \pi \left[\frac{1}{2}y^2 - \frac{1}{3}y^3 \right]_0^1 = \pi \left[\frac{1}{2} - \frac{1}{3} \right] = \frac{\pi}{6}$$

- (c) A cross-section is a washer with inner radius $2-x$ and outer radius $2-x^2$.

$$V = \int_0^1 \pi \left[(2-x^2)^2 - (2-x)^2 \right] dx = \int_0^1 \pi (x^4 - 5x^2 + 4x) \, dx = \pi \left[\frac{1}{5}x^5 - \frac{5}{3}x^3 + 2x^2 \right]_0^1 \\ = \pi \left[\frac{1}{5} - \frac{5}{3} + 2 \right] = \frac{8\pi}{15}$$

16. (a) $A = \int_0^1 (2x - x^2 - x^3) \, dx = \left[x^2 - \frac{1}{3}x^3 - \frac{1}{4}x^4 \right]_0^1 = 1 - \frac{1}{3} - \frac{1}{4} = \frac{5}{12}$

- (b) A cross-section is a washer with inner radius x^3 and outer radius $2x - x^2$, so its area is $\pi(2x - x^2)^2 - \pi(x^3)^2$.

$$V = \int_0^1 A(x) \, dx = \int_0^1 \pi \left[(2x - x^2)^2 - (x^3)^2 \right] dx = \int_0^1 \pi (4x^2 - 4x^3 + x^4 - x^6) \, dx \\ = \pi \left[\frac{4}{3}x^3 - x^4 + \frac{1}{5}x^5 - \frac{1}{7}x^7 \right]_0^1 = \pi \left(\frac{4}{3} - 1 + \frac{1}{5} - \frac{1}{7} \right) = \frac{41\pi}{105}$$

- (c) Using the method of cylindrical shells,

$$V = \int_0^1 2\pi x (2x - x^2 - x^3) \, dx = \int_0^1 2\pi (2x^2 - x^3 - x^4) \, dx = 2\pi \left[\frac{2}{3}x^3 - \frac{1}{4}x^4 - \frac{1}{5}x^5 \right]_0^1 \\ = 2\pi \left(\frac{2}{3} - \frac{1}{4} - \frac{1}{5} \right) = \frac{13\pi}{30}.$$

17. (a) Using the Midpoint Rule on $[0, 1]$ with $f(x) = \tan(x^2)$ and $n = 4$, we estimate

$$A = \int_0^1 \tan(x^2) \, dx \approx \frac{1}{4} \left[\tan\left(\left(\frac{1}{8}\right)^2\right) + \tan\left(\left(\frac{3}{8}\right)^2\right) + \tan\left(\left(\frac{5}{8}\right)^2\right) + \tan\left(\left(\frac{7}{8}\right)^2\right) \right] \approx \frac{1}{4}(1.53) \approx 0.38$$

- (b) Using the Midpoint Rule on $[0, 1]$ with $f(x) = \pi \tan^2(x^2)$ (for disks) and $n = 4$, we estimate

$$V = \int_0^1 f(x) \, dx \approx \frac{1}{4} \pi \left[\tan^2\left(\left(\frac{1}{8}\right)^2\right) + \tan^2\left(\left(\frac{3}{8}\right)^2\right) + \tan^2\left(\left(\frac{5}{8}\right)^2\right) + \tan^2\left(\left(\frac{7}{8}\right)^2\right) \right] \approx \frac{\pi}{4}(1.114) \approx 0.87$$

18. (a)

From the graph, we see that the curves intersect at $x = 0$ and at $x = a \approx 0.75$, with $1 - x^2 > x^6 - x + 1$ on $(0, a)$.

- (b) The area of $\mathcal{R}$ is

$$A = \int_0^a [(1 - x^2) - (x^6 - x + 1)] \, dx = \left[-\frac{1}{3}x^3 - \frac{1}{7}x^7 + \frac{1}{2}x^2 \right]_0^a \approx 0.12$$

- (c) Using washers, the volume generated when $\mathcal{R}$ is rotated about the x -axis is

$$V = \pi \int_0^a \left[(1 - x^2)^2 - (x^6 - x + 1)^2 \right] dx = \pi \int_0^a (-x^{12} + 2x^7 - 2x^6 + x^4 - 3x^2 + 2x) \, dx \\ = \pi \left[-\frac{1}{13}x^{13} + \frac{1}{4}x^8 - \frac{2}{7}x^7 + \frac{1}{5}x^5 - x^3 + x^2 \right]_0^a \approx 0.54$$

(d) Using shells, the volume generated when $\mathcal{R}$ is rotated about the y -axis is

$$\begin{aligned} V &= \int_0^a 2\pi x [(1-x^2) - (x^6 - x + 1)] dx = 2\pi \int_0^a (-x^3 - x^7 + x^2) dx \\ &= 2\pi \left[-\frac{1}{4}x^4 - \frac{1}{8}x^8 + \frac{1}{3}x^3 \right]_0^a \approx 0.31 \end{aligned}$$

19. The solid is obtained by rotating the region $\mathcal{R} = \{(x, y) \mid 0 \leq x \leq \frac{\pi}{2}, 0 \leq y \leq \cos x\}$ about the y -axis.
20. The solid is obtained by rotating the region $\mathcal{R} = \{(x, y) \mid 0 \leq x \leq \frac{\pi}{2}, 0 \leq y \leq \sqrt{2} \cos x\}$ about the x -axis.
21. The solid is obtained by rotating the region $\mathcal{R} = \{(x, y) \mid 0 \leq y \leq 2, 0 \leq x \leq 4 - y^2\}$ about the x -axis.
22. The solid is obtained by rotating the region $\mathcal{R} = \{(x, y) \mid 0 \leq x \leq 1, 2 - \sqrt{x} \leq y \leq 2 - x^2\}$ about the x -axis.

Or: The solid is obtained by rotating the region $\mathcal{R} = \{(x, y) \mid 0 \leq x \leq 1, x^2 \leq y \leq \sqrt{x}\}$ about the line $y = 2$.

23. Take the base to be the disk $x^2 + y^2 \leq 9$. Then $V = \int_{-3}^3 A(x) dx$, where $A(x_0)$ is the area of the isosceles right triangle whose hypotenuse lies along the line $x = x_0$ in the xy -plane. The length of the hypotenuse is $2\sqrt{9 - x^2}$ and the length of each leg is $\sqrt{2}\sqrt{9 - x^2}$. $A(x) = \frac{1}{2}(\sqrt{2}\sqrt{9 - x^2})^2 = 9 - x^2$, so
- $$V = 2 \int_0^3 A(x) dx = 2 \int_0^3 (9 - x^2) dx = 2 \left[9x - \frac{1}{3}x^3 \right]_0^3 = 2(27 - 9) = 36.$$

24. $V = \int_{-1}^1 A(x) dx = 2 \int_0^1 A(x) dx = 2 \int_0^1 [(2 - x^2) - x^2]^2 dx = 2 \int_0^1 [2(1 - x^2)]^2 dx$
- $$= 8 \int_0^1 (1 - 2x^2 + x^4) dx = 8 \left[x - \frac{2}{3}x^3 + \frac{1}{5}x^5 \right]_0^1 = 8 \left(1 - \frac{2}{3} + \frac{1}{5} \right) = \frac{64}{15}$$

25. Equilateral triangles with sides measuring $\frac{1}{4}x$ meters have height $\frac{1}{4}x \sin 60^\circ = \frac{\sqrt{3}}{8}x$. Therefore,

$$A(x) = \frac{1}{2} \cdot \frac{1}{4}x \cdot \frac{\sqrt{3}}{8}x = \frac{\sqrt{3}}{64}x^2. \quad V = \int_0^{20} A(x) dx = \frac{\sqrt{3}}{64} \int_0^{20} x^2 dx = \frac{\sqrt{3}}{64} \left[\frac{1}{3}x^3 \right]_0^{20} = \frac{8000\sqrt{3}}{64 \cdot 3} = \frac{125\sqrt{3}}{3} \text{ m}^3.$$

26. (a) By the symmetry of the problem, we consider only the solid to the right of the origin. The semicircular cross-sections perpendicular to the x -axis have radius $1 - x$, so $A(x) = \frac{1}{2}\pi(1 - x)^2$. Now we can calculate

$$V = 2 \int_0^1 A(x) dx = 2 \int_0^1 \frac{1}{2}\pi(1 - x)^2 dx = \int_0^1 \pi(1 - x)^2 dx = -\frac{\pi}{3}[(1 - x)^3]_0^1 = \frac{\pi}{3}.$$

- (b) Cut the solid with a plane perpendicular to the x -axis and passing through the y -axis. Fold the half of the solid in the region $x \leq 0$ under the xy -plane so that the point $(-1, 0)$ comes around and touches the point $(1, 0)$. The resulting solid is a right circular cone of radius 1 with vertex at $(x, y, z) = (1, 0, 0)$ and with its base in the yz -plane, centered at the origin. The volume of this cone is $\frac{1}{3}\pi r^2 h = \frac{1}{3}\pi \cdot 1^2 \cdot 1 = \frac{\pi}{3}$.

27. $f(x) = kx \Rightarrow 30 \text{ N} = k(15 - 12) \text{ cm} \Rightarrow k = 10 \text{ N/cm} = 1000 \text{ N/m}. \quad 20 \text{ cm} - 12 \text{ cm} = 0.08 \text{ m} \Rightarrow$

$$W = \int_0^{0.08} kx dx = 1000 \int_0^{0.08} x dx = 500 [x^2]_0^{0.08} = 500(0.08)^2 = 3.2 \text{ N}\cdot\text{m} = 3.2 \text{ J}.$$

28. The work needed to raise the elevator alone is $1600 \text{ lb} \times 30 \text{ ft} = 48,000 \text{ ft}\cdot\text{lb}$. The work needed to raise the bottom 170 ft of cable is $170 \text{ ft} \times 10 \text{ lb/ft} \times 30 \text{ ft} = 51,000 \text{ ft}\cdot\text{lb}$. The work needed to raise the top 30 ft of cable is

$$\int_0^{30} 10x \, dx = [5x^2]_0^{30} = 5 \cdot 900 = 4500 \text{ ft}\cdot\text{lb}. \text{ Adding these, we see that the total work needed is}$$

$$48,000 + 51,000 + 4,500 = 103,500 \text{ ft}\cdot\text{lb}.$$

29. (a) The parabola has equation $y = ax^2$ with vertex at the origin and passing through $(4, 4)$. $4 = a \cdot 4^2 \Rightarrow a = \frac{1}{4} \Rightarrow y = \frac{1}{4}x^2 \Rightarrow x^2 = 4y \Rightarrow x = 2\sqrt{y}$. Each circular disk has radius $2\sqrt{y}$ and is moved $4 - y$ ft.

$$W = \int_0^4 \pi (2\sqrt{y})^2 62.5 (4 - y) \, dy = 250\pi \int_0^4 y(4 - y) \, dy$$

$$= 250\pi \left[2y^2 - \frac{1}{3}y^3 \right]_0^4 = 250\pi \left(32 - \frac{64}{3} \right) = \frac{8000\pi}{3} \approx 8378 \text{ ft}\cdot\text{lb}$$

- (b) In part (a) we knew the final water level (0) but not the amount of work done. Here we use the same equation, except with the work fixed, and the lower limit of integration (that is, the final water level — call it h)

$$\text{unknown: } W = 4000 \Leftrightarrow 250\pi \left[2y^2 - \frac{1}{3}y^3 \right]_h^4 = 4000 \Leftrightarrow$$

$$\frac{16}{\pi} = \left[\left(32 - \frac{64}{3} \right) - \left(2h^2 - \frac{1}{3}h^3 \right) \right] \Leftrightarrow h^3 - 6h^2 + 32 - \frac{48}{\pi} = 0.$$

We graph the function $f(h) = h^3 - 6h^2 + 32 - \frac{48}{\pi}$ on the interval $[0, 4]$ to see where it is 0. From the graph, $f(h) = 0$ for $h \approx 2.1$. So the depth of water remaining is about 2.1 ft.

30. $f_{\text{ave}} = \frac{1}{10-0} \int_0^{10} t \sin(t^2) \, dt = \frac{1}{10} \int_0^{100} \sin u \left(\frac{1}{2} du \right) \quad [u = t^2, du = 2t \, dt]$

$$= \frac{1}{20} \left[-\cos u \right]_0^{100} = \frac{1}{20} (-\cos 100 + \cos 0) = \frac{1}{20} (1 - \cos 100) \approx 0.007$$

31. $\lim_{h \rightarrow 0} f_{\text{ave}} = \lim_{h \rightarrow 0} \frac{1}{(x+h) - x} \int_x^{x+h} f(t) \, dt = \lim_{h \rightarrow 0} \frac{F(x+h) - F(x)}{h}$, where $F(x) = \int_a^x f(t) \, dt$. But we recognize this limit as being $F'(x)$ by the definition of a derivative. Therefore, $\lim_{h \rightarrow 0} f_{\text{ave}} = F'(x) = f(x)$ by FTC1.

32. (a) $\mathcal{R}_1$ is the region below the graph of $y = x^2$ and above the x -axis between $x = 0$ and $x = b$, and $\mathcal{R}_2$ is the region to the left of the graph of $x = \sqrt{y}$ and to the right of the y -axis between $y = 0$ and $y = b^2$. So the area of $\mathcal{R}_1$ is $A_1 = \int_0^b x^2 \, dx = \left[\frac{1}{3}x^3 \right]_0^b = \frac{1}{3}b^3$, and the area of $\mathcal{R}_2$ is $A_2 = \int_0^{b^2} \sqrt{y} \, dy = \left[\frac{2}{3}y^{3/2} \right]_0^{b^2} = \frac{2}{3}b^3$. So there is no solution to $A_1 = A_2$ for $b \neq 0$.

- (b) Using disks, we calculate the volume of rotation of $\mathcal{R}_1$ about the x -axis to be $V_{1,x} = \pi \int_0^b (x^2)^2 dx = \frac{1}{5} \pi b^5$.

Using cylindrical shells, we calculate the volume of rotation of $\mathcal{R}_1$ about the y -axis to be

$$V_{1,y} = 2\pi \int_0^b x(x^2) dx = 2\pi \left[\frac{1}{4} x^4 \right]_0^b = \frac{1}{2} \pi b^4. \text{ So } V_{1,x} = V_{1,y} \Leftrightarrow \frac{1}{5} \pi b^5 = \frac{1}{2} \pi b^4 \Leftrightarrow 2b = 5 \Leftrightarrow$$

$b = \frac{5}{2}$. So the volumes of rotation about the x - and y -axes are the same for $b = \frac{5}{2}$.

- (c) We use cylindrical shells to calculate the volume of rotation of $\mathcal{R}_2$ about the x -axis:

$$\mathcal{R}_{2,x} = 2\pi \int_0^{b^2} y(\sqrt{y}) dy = 2\pi \left[\frac{2}{5} y^{5/2} \right]_0^{b^2} = \frac{4}{5} \pi b^5. \text{ We already know the volume of rotation of } \mathcal{R}_1 \text{ about the}$$

x -axis from part (b), and $\mathcal{R}_{1,x} = \mathcal{R}_{2,x} \Leftrightarrow \frac{1}{5} \pi b^5 = \frac{4}{5} \pi b^5$, which has no solution for $b \neq 0$.

- (d) We use disks to calculate the volume of rotation of $\mathcal{R}_2$ about the y -axis:

$$\mathcal{R}_{2,y} = \pi \int_0^{b^2} (\sqrt{y})^2 dy = \pi \left[\frac{1}{2} y^2 \right]_0^{b^2} = \frac{1}{2} \pi b^4. \text{ We know the volume of rotation of } \mathcal{R}_1 \text{ about the } y\text{-axis from}$$

part (b), and $\mathcal{R}_{1,y} = \mathcal{R}_{2,y} \Leftrightarrow \frac{1}{2} \pi b^4 = \frac{1}{2} \pi b^4$. But this equation is true for all b , so the volumes of rotation about the y -axis are equal for all values of b .

□ PROBLEMS PLUS

1. (a) The area under the graph of f from 0 to t is equal to $\int_0^t f(x) dx$, so the requirement is that $\int_0^t f(x) dx = t^3$ for all t . We differentiate both sides of this equation with respect to t (with the help of FTC1) to get $f(t) = 3t^2$.

This function is positive and continuous, as required.

- (b) The volume generated from $x = 0$ to $x = b$ is $\int_0^b \pi[f(x)]^2 dx$. Hence, we are given that $b^2 = \int_0^b \pi[f(x)]^2 dx$ for all $b > 0$. Differentiating both sides of this equation with respect to b using the Fundamental Theorem of Calculus gives $2b = \pi[f(b)]^2 \Rightarrow f(b) = \sqrt{2b/\pi}$, since f is positive. Therefore, $f(x) = \sqrt{2x/\pi}$.

2. The total area of the region bounded by the parabola

$y = x - x^2 = x(1 - x)$ and the x -axis is

$$\int_0^1 (x - x^2) dx = \left[\frac{1}{2}x^2 - \frac{1}{3}x^3 \right]_0^1 = \frac{1}{6}.$$

Let the slope of the line we are looking for be m . Then the area above this

line but below the parabola is $\int_0^a [(x - x^2) - mx] dx$, where a is the x -coordinate of the point of intersection of the line and the parabola. We

find the point of intersection by solving the equation $x - x^2 = mx \Leftrightarrow$

$1 - x = m \Leftrightarrow x = 1 - m$. So the value of a is $1 - m$, and

$$\begin{aligned} \int_0^{1-m} [(x - x^2) - mx] dx &= \int_0^{1-m} [(1 - m)x - x^2] dx = \left[\frac{1}{2}(1 - m)x^2 - \frac{1}{3}x^3 \right]_0^{1-m} \\ &= \frac{1}{2}(1 - m)(1 - m)^2 - \frac{1}{3}(1 - m)^3 = \frac{1}{6}(1 - m)^3 \end{aligned}$$

We want this to be half of $\frac{1}{6}$, so $\frac{1}{6}(1 - m)^3 = \frac{1}{12} \Leftrightarrow (1 - m)^3 = \frac{6}{12} \Leftrightarrow$

$1 - m = \sqrt[3]{\frac{1}{2}} \Leftrightarrow m = 1 - \sqrt[3]{\frac{1}{2}}$. So the slope of the required line is $1 - \sqrt[3]{\frac{1}{2}} \approx 0.206$.

3. Let a and b be the x -coordinates of the points where the line intersects the

curve. From the figure, $R_1 = R_2 \Rightarrow$

$$\int_0^a [c - (8x - 27x^3)] dx = \int_a^b [(8x - 27x^3) - c] dx$$

$$\left[cx - 4x^2 + \frac{27}{4}x^4 \right]_0^a = \left[4x^2 - \frac{27}{4}x^4 - cx \right]_a^b$$

$$ac - 4a^2 + \frac{27}{4}a^4 = (4b^2 - \frac{27}{4}b^4 - bc) - (4a^2 - \frac{27}{4}a^4 - ac)$$

$$0 = 4b^2 - \frac{27}{4}b^4 - bc = 4b^2 - \frac{27}{4}b^4 - b(8b - 27b^3)$$

$$= 4b^2 - \frac{27}{4}b^4 - 8b^2 + 27b^4 = \frac{81}{4}b^4 - 4b^2$$

$$= b^2 \left(\frac{81}{4}b^2 - 4 \right)$$

So for $b > 0$, $b^2 = \frac{16}{81} \Rightarrow b = \frac{4}{9}$. Thus, $c = 8b - 27b^3 = 8\left(\frac{4}{9}\right) - 27\left(\frac{64}{729}\right) = \frac{32}{9} - \frac{64}{27} = \frac{32}{27}$.

4. (a) Take slices perpendicular to the line through the center C of the bottom of the glass and the point P where the top surface of the water meets the bottom of the glass.

A typical rectangular cross-section y units above the axis of the glass has width $2|QR| = 2\sqrt{r^2 - y^2}$ and length $h = |QS| = \frac{L}{2r}(r - y)$. [Triangles PQS and PAB are similar, so $\frac{h}{L} = \frac{|PQ|}{|PA|} = \frac{r - y}{2r}$.] Thus,

$$\begin{aligned} V &= \int_{-r}^r 2\sqrt{r^2 - y^2} \cdot \frac{L}{2r}(r - y) dy = L \int_{-r}^r \left(1 - \frac{y}{r}\right) \sqrt{r^2 - y^2} dy \\ &= L \int_{-r}^r \sqrt{r^2 - y^2} dy - \frac{L}{r} \int_{-r}^r y \sqrt{r^2 - y^2} dy \\ &= L \cdot \frac{\pi r^2}{2} - \frac{L}{r} \cdot 0 \quad \left[\begin{array}{l} \text{the first integral is the area of a semicircle of radius } r, \\ \text{and the second has an odd integrand} \end{array} \right] = \frac{\pi r^2 L}{2} \end{aligned}$$

- (b) Slice parallel to the plane through the axis of the glass and the point of contact P . (This is the plane determined by P , B , and C in the figure.) $STUV$ is a typical trapezoidal slice. With respect to an x -axis with origin at C as shown, if S and V have x -coordinate x , then $|SV| = 2\sqrt{r^2 - x^2}$. Projecting the trapezoid $STUV$ onto the plane of the triangle PAB (call the projection $S'T'U'V'$), we see that $|AP| = 2r$, $|SV| = 2\sqrt{r^2 - x^2}$, and $|S'P| = |V'A| = \frac{1}{2}(|AP| - |SV|) = r - \sqrt{r^2 - x^2}$.

By similar triangles, $\frac{|ST|}{|S'P|} = \frac{|AB|}{|AP|}$, so $|ST| = (r - \sqrt{r^2 - x^2}) \cdot \frac{L}{2r}$. In the same way, we find that

$$\frac{|VU|}{|V'P|} = \frac{|AB|}{|AP|}, \text{ so } |VU| = |V'P| \cdot \frac{L}{2r} = (r + \sqrt{r^2 - x^2}) \cdot \frac{L}{2r}.$$

The area $A(x)$ of the trapezoid $STUV$ is $\frac{1}{2}|SV| \cdot (|ST| + |VU|)$; that is,

$$A(x) = \frac{1}{2} \cdot 2\sqrt{r^2 - x^2} \cdot \left[(r - \sqrt{r^2 - x^2}) \cdot \frac{L}{2r} + (r + \sqrt{r^2 - x^2}) \cdot \frac{L}{2r} \right] = L\sqrt{r^2 - x^2}. \text{ Thus,}$$

$$V = \int_{-r}^r A(x) dx = L \int_{-r}^r \sqrt{r^2 - x^2} dx = L \cdot \frac{\pi r^2}{2} = \frac{\pi r^2 L}{2}.$$

- (c) See the computation of V in part (a) or part (b).

(d) The volume of the water is exactly half the volume of the cylindrical glass, so $V = \frac{1}{2}\pi r^2 L$.

(e)

Choose x -, y -, and z -axes as shown in the figure. Then slices perpendicular to the x -axis are triangular, slices perpendicular to the y -axis are rectangular, and slices perpendicular to the z -axis are segments of circles. Using triangular slices, we find that the area $A(x)$ of a typical slice DEF , where D has x -coordinate x , is given by

$$A(x) = \frac{1}{2}|DE| \cdot |EF| = \frac{1}{2}|DE| \cdot \left(\frac{L}{r}|DE|\right) = \frac{L}{2r}|DE|^2 = \frac{L}{2r}(r^2 - x^2). \text{ Thus,}$$

$$\begin{aligned} V &= \int_{-r}^r A(x) dx = \frac{L}{2r} \int_{-r}^r (r^2 - x^2) dx = \frac{L}{r} \int_0^r (r^2 - x^2) dx = \frac{L}{r} \left[r^2 x - \frac{x^3}{3} \right]_0^r \\ &= \frac{L}{r} \left(r^3 - \frac{r^3}{3} \right) = \frac{L}{r} \cdot \frac{2}{3} r^3 = \frac{2}{3} r^2 L \text{ [This is } 2/(3\pi) \approx 0.21 \text{ of the volume of the glass.]} \end{aligned}$$

5. (a) $V = \pi h^2(r - h/3) = \frac{1}{3}\pi h^2(3r - h)$. See the solution to Exercise 6.2.49.

(b) The smaller segment has height $h = 1 - x$ and so by part (a) its volume is

$$\begin{aligned} V &= \frac{1}{3}\pi(1-x)^2[3(1) - (1-x)] = \frac{1}{3}\pi(x-1)^2(x+2). \text{ This volume must be } \frac{1}{3} \text{ of the total volume of the} \\ &\text{sphere, which is } \frac{4}{3}\pi(1)^3. \text{ So } \frac{1}{3}\pi(x-1)^2(x+2) = \frac{1}{3}\left(\frac{4}{3}\pi\right) \Rightarrow (x^2 - 2x + 1)(x+2) = \frac{4}{3} \Rightarrow \\ &x^3 - 3x + 2 = \frac{4}{3} \Rightarrow 3x^3 - 9x + 2 = 0. \text{ Using Newton's method with } f(x) = 3x^3 - 9x + 2, \\ &f'(x) = 9x^2 - 9, \text{ we get } x_{n+1} = x_n - \frac{3x_n^3 - 9x_n + 2}{9x_n^2 - 9}. \text{ Taking } x_1 = 0, \text{ we get } x_2 \approx 0.2222, \text{ and} \\ &x_3 \approx 0.2261 \approx x_4, \text{ so, correct to four decimal places, } x \approx 0.2261. \end{aligned}$$

(c) With $r = 0.5$ and $s = 0.75$, the equation $x^3 - 3rx^2 + 4r^3s = 0$ becomes $x^3 - 3(0.5)x^2 + 4(0.5)^3(0.75) = 0$
 $\Rightarrow x^3 - \frac{3}{2}x^2 + 4\left(\frac{1}{8}\right)\frac{3}{4} = 0 \Rightarrow 8x^3 - 12x^2 + 3 = 0$. We use Newton's method with

$$\begin{aligned} f(x) &= 8x^3 - 12x^2 + 3, f'(x) = 24x^2 - 24x, \text{ so } x_{n+1} = x_n - \frac{8x_n^3 - 12x_n^2 + 3}{24x_n^2 - 24x_n}. \text{ Take } x_1 = 0.5. \text{ Then} \\ &x_2 \approx 0.6667, \text{ and } x_3 \approx 0.6736 \approx x_4. \text{ So to four decimal places the depth is } 0.6736 \text{ m.} \end{aligned}$$

(d) (i) From part (a) with $r = 5$ in., the volume of water in the bowl is

$$\begin{aligned} V &= \frac{1}{3}\pi h^2(3r - h) = \frac{1}{3}\pi h^2(15 - h) = 5\pi h^2 - \frac{1}{3}\pi h^3. \text{ We are given that } \frac{dV}{dt} = 0.2 \text{ m}^3/\text{s} \text{ and we want to} \\ &\text{find } \frac{dh}{dt} \text{ when } h = 3. \text{ Now } \frac{dV}{dt} = 10\pi h \frac{dh}{dt} - \pi h^2 \frac{dh}{dt}, \text{ so } \frac{dh}{dt} = \frac{0.2}{\pi(10h - h^2)}. \text{ When } h = 3, \text{ we have} \\ &\frac{dh}{dt} = \frac{0.2}{\pi(10 \cdot 3 - 3^2)} = \frac{1}{105\pi} \approx 0.003 \text{ in/s.} \end{aligned}$$

(ii) From part (a), the volume of water required to fill the bowl from the instant that the water is 4 in. deep is

$$V = \frac{1}{2} \cdot \frac{4}{3} \pi (5)^3 - \frac{1}{3} \pi (4)^2 (15 - 4) = \frac{2}{3} \cdot 125\pi - \frac{16}{3} \cdot 11\pi = \frac{74}{3} \pi. \text{ To find the time required to fill the bowl we divide this volume by the rate: Time} = \frac{74\pi/3}{0.2} = \frac{370\pi}{3} \approx 387 \text{ s} \approx 6.5 \text{ min}$$

6. (a) The volume above the surface is $\int_0^{L-h} A(y) dy = \int_{-h}^{L-h} A(y) dy - \int_{-h}^0 A(y) dy$. So the proportion of volume

above the surface is $\frac{\int_0^{L-h} A(y) dy}{\int_{-h}^{L-h} A(y) dy} = \frac{\int_{-h}^{L-h} A(y) dy - \int_{-h}^0 A(y) dy}{\int_{-h}^{L-h} A(y) dy}$. Now by Archimedes' Principle, we

$$\text{have } F = W \Rightarrow \rho_f g \int_{-h}^0 A(y) dy = \rho_0 g \int_{-h}^{L-h} A(y) dy, \text{ so } \int_{-h}^0 A(y) dy = (\rho_0/\rho_f) \int_{-h}^{L-h} A(y) dy.$$

Therefore, $\frac{\int_0^{L-h} A(y) dy}{\int_{-h}^{L-h} A(y) dy} = \frac{\int_{-h}^{L-h} A(y) dy - (\rho_0/\rho_f) \int_{-h}^{L-h} A(y) dy}{\int_{-h}^{L-h} A(y) dy} = \frac{\rho_f - \rho_0}{\rho_f}$, so the percentage of

volume above the surface is $100 \left(\frac{\rho_f - \rho_0}{\rho_f} \right) \%$.

- (b) For an iceberg, the percentage of volume above the surface is $100 \left(\frac{1030 - 917}{1030} \right) \% \approx 11\%$.

- (c) No, the water does not overflow. Let V_i be the volume of the ice cube, and let V_w be the volume of the water which results from the melting. Then by the formula derived in part (a), the volume of ice above the surface of the water is $[(\rho_f - \rho_0)/\rho_f] V_i$, so the volume below the surface is $V_i - [(\rho_f - \rho_0)/\rho_f] V_i = (\rho_0/\rho_f) V_i$.

Now the mass of the ice cube is the same as the mass of the water which is created when it melts, namely

$$m = \rho_0 V_i = \rho_f V_w \Rightarrow V_w = (\rho_0/\rho_f) V_i. \text{ So when the ice cube melts, the volume of the resulting water is the same as the underwater volume of the ice cube, and so the water does not overflow.}$$

- (d)

The figure shows the instant when the height of the exposed part of the ball is y . Using the formula in Problem 5(a) with $r = 0.4$ and

$h = 0.8 - y$, we see that the volume of the submerged part of the

sphere is $\frac{1}{3} \pi (0.8 - y)^2 [1.2 - (0.8 - y)]$, so its weight is

$1000g \cdot \frac{1}{3} \pi s^2 (1.2 - s)$, where $s = 0.8 - y$. Then the work done to submerge the sphere is

$$\begin{aligned} W &= \int_0^{0.8} g \frac{1000}{3} \pi s^2 (1.2 - s) ds = g \frac{1000}{3} \pi \int_0^{0.8} (1.2s^2 - s^3) ds \\ &= g \frac{1000}{3} \pi \left[0.4s^3 - \frac{1}{4}s^4 \right]_0^{0.8} = g \frac{1000}{3} \pi (0.2048 - 0.1024) \\ &= 9.8 \frac{1000}{3} \pi (0.1024) \approx 1.05 \times 10^3 \text{ joules} \end{aligned}$$

7. We are given that the rate of change of the volume of water is $\frac{dV}{dt} = -kA(x)$, where k is some positive constant

and $A(x)$ is the area of the surface when the water has depth x . Now we are concerned with the rate of change of

the depth of the water with respect to time, that is, $\frac{dx}{dt}$. But by the Chain Rule, $\frac{dV}{dt} = \frac{dV}{dx} \frac{dx}{dt}$, so the first equation

can be written $\frac{dV}{dx} \frac{dx}{dt} = -kA(x)$ (*). Also, we know that the total volume of water up to a depth x is

$V(x) = \int_0^x A(s) ds$, where $A(s)$ is the area of a cross-section of the water at a depth s . Differentiating this equation with respect to x , we get $dV/dx = A(x)$. Substituting this into equation $\star$, we get

$$A(x)(dx/dt) = -kA(x) \Rightarrow dx/dt = -k, \text{ a constant.}$$

8. A typical sphere of radius r is shown in the figure. We wish to maximize the shaded volume V , which can be thought of as the volume of a hemisphere of radius r minus the volume of the spherical cap with height $h = 1 - \sqrt{1 - r^2}$ and radius 1.

$$\begin{aligned} V &= \frac{1}{2} \cdot \frac{4}{3} \pi r^3 - \frac{1}{3} \pi (1 - \sqrt{1 - r^2})^2 [3(1) - (1 - \sqrt{1 - r^2})] \quad [\text{by Problem 5(a)}] \\ &= \frac{1}{3} \pi [2r^3 - (2 - 2\sqrt{1 - r^2} - r^2)(2 + \sqrt{1 - r^2})] \\ &= \frac{1}{3} \pi [2r^3 - 2 + (r^2 + 2)\sqrt{1 - r^2}] \end{aligned}$$

$$\begin{aligned} V' &= \frac{1}{3} \pi \left[6r^2 + \frac{(r^2 + 2)(-r)}{\sqrt{1 - r^2}} + \sqrt{1 - r^2}(2r) \right] = \frac{1}{3} \pi \left[\frac{6r^2 \sqrt{1 - r^2} - r(r^2 + 2) + 2r(1 - r^2)}{\sqrt{1 - r^2}} \right] \\ &= \frac{1}{3} \pi \left(\frac{6r^2 \sqrt{1 - r^2} - 3r^3}{\sqrt{1 - r^2}} \right) = \frac{\pi r^2 (2\sqrt{1 - r^2} - r)}{\sqrt{1 - r^2}} \end{aligned}$$

$V'(r) = 0 \Leftrightarrow 2\sqrt{1 - r^2} = r \Leftrightarrow 4 - 4r^2 = r^2 \Leftrightarrow r^2 = \frac{4}{5} \Leftrightarrow r = \frac{2}{\sqrt{5}} \approx 0.89$. Since $V'(r) > 0$ for $0 < r < \frac{2}{\sqrt{5}}$ and $V'(r) < 0$ for $\frac{2}{\sqrt{5}} < r < 1$, we know that V attains a maximum at $r = \frac{2}{\sqrt{5}}$.

9. We must find expressions for the areas A and B , and then set them equal and see what this says about the curve C .

If $P = (a, 2a^2)$, then area A is just $\int_0^a (2x^2 - x^2) dx = \int_0^a x^2 dx = \frac{1}{3}a^3$. To find area B , we use y as the variable of integration. So we find the equation of the middle curve as a function of y : $y = 2x^2 \Leftrightarrow x = \sqrt{y/2}$,

since we are concerned with the first quadrant only. We can express area B as

$$\int_0^{2a^2} [\sqrt{y/2} - C(y)] dy = \left[\frac{4}{3}(y/2)^{3/2} \right]_0^{2a^2} - \int_0^{2a^2} C(y) dy = \frac{4}{3}a^3 - \int_0^{2a^2} C(y) dy, \text{ where } C(y) \text{ is the function}$$

with graph C . Setting $A = B$, we get $\frac{1}{3}a^3 = \frac{4}{3}a^3 - \int_0^{2a^2} C(y) dy \Leftrightarrow \int_0^{2a^2} C(y) dy = a^3$. Now we differentiate this equation with respect to a using the Chain Rule and the Fundamental Theorem:

$$\begin{aligned} C(2a^2)(4a) &= 3a^2 \Rightarrow C(y) = \frac{3}{4}\sqrt{y/2}, \text{ where } y = 2a^2. \text{ Now we can solve for } y: x = \frac{3}{4}\sqrt{y/2} \Rightarrow \\ x^2 &= \frac{9}{16}(y/2) \Rightarrow y = \frac{32}{9}x^2. \end{aligned}$$

10. We want to find the volume of that part of the sphere which is below the surface of the water. As we can see from the diagram, this region is a cap of a sphere with radius r and height $r + d$. If we can find an expression for d in terms of h , r and θ , then we can determine the volume of the region [see Problem 5(a)], and then differentiate with respect to r to find the maximum. We see that

$$\sin \theta = \frac{r}{h - d} \Leftrightarrow h - d = \frac{r}{\sin \theta} \Leftrightarrow d = h - r \csc \theta.$$

Now we can use the formula from Problem 5(a) to find the volume of water displaced:

$$\begin{aligned} V &= \frac{1}{3}\pi h^2(3r - h) = \frac{1}{3}\pi(r + d)^2[3r - (r + d)] = \frac{1}{3}\pi(r + h - r \csc \theta)^2(2r - h + r \csc \theta) \\ &= \frac{\pi}{3}[r(1 - \csc \theta) + h]^2[r(2 + \csc \theta) - h] \end{aligned}$$

Now we differentiate with respect to r :

$$\begin{aligned} dV/dr &= \frac{\pi}{3}([r(1 - \csc \theta) + h]^2(2 + \csc \theta) + 2[r(1 - \csc \theta) + h](1 - \csc \theta)[r(2 + \csc \theta) - h]) \\ &= \frac{\pi}{3}[r(1 - \csc \theta) + h]([r(1 - \csc \theta) + h](2 + \csc \theta) + 2(1 - \csc \theta)[r(2 + \csc \theta) - h]) \\ &= \frac{\pi}{3}[r(1 - \csc \theta) + h](3(2 + \csc \theta)(1 - \csc \theta)r + [(2 + \csc \theta) - 2(1 - \csc \theta)]h) \\ &= \frac{\pi}{3}[r(1 - \csc \theta) + h][3(2 + \csc \theta)(1 - \csc \theta)r + 3h \csc \theta] \end{aligned}$$

This is 0 when $r = \frac{h}{\csc \theta - 1}$ and when $r = \frac{h \csc \theta}{(\csc \theta + 2)(\csc \theta - 1)}$. Now since $V\left(\frac{h}{\csc \theta - 1}\right) = 0$

(the first factor vanishes; this corresponds to $d = -r$), the maximum volume of water is displaced when

$r = \frac{h \csc \theta}{(\csc \theta - 1)(\csc \theta + 2)}$. (Our intuition tells us that a maximum value does exist, and it must occur at a critical

number.) Multiplying numerator and denominator by $\sin^2 \theta$, we get an alternative form of the answer:

$$r = \frac{h \sin \theta}{\sin \theta + \cos 2\theta}.$$

11. (a) Stacking disks along the y -axis gives us $V = \int_0^h \pi [f(y)]^2 dy$.

(b) Using the Chain Rule, $\frac{dV}{dt} = \frac{dV}{dh} \cdot \frac{dh}{dt} = \pi [f(h)]^2 \frac{dh}{dt}$.

(c) $kA \sqrt{h} = \pi [f(h)]^2 \frac{dh}{dt}$. Set $\frac{dh}{dt} = C$: $\pi [f(h)]^2 C = kA \sqrt{h} \Rightarrow [f(h)]^2 = \frac{kA}{\pi C} \sqrt{h} \Rightarrow$

$f(h) = \sqrt{\frac{kA}{\pi C}} h^{1/4}$; that is, $f(y) = \sqrt{\frac{kA}{\pi C}} y^{1/4}$. The advantage of having $\frac{dh}{dt} = C$ is that the markings on the container are equally spaced.

12. (a) We first use the cylindrical shell method to express the volume V in terms of h , r , and ω :

$$\begin{aligned} V &= \int_0^r 2\pi xy \, dx = \int_0^r 2\pi x \left[h + \frac{\omega^2 x^2}{2g} \right] dx = 2\pi \int_0^r \left(hx + \frac{\omega^2 x^3}{2g} \right) dx \\ &= 2\pi \left[\frac{hx^2}{2} + \frac{\omega^2 x^4}{8g} \right]_0^r = 2\pi \left[\frac{hr^2}{2} + \frac{\omega^2 r^4}{8g} \right] = \pi hr^2 + \frac{\pi \omega^2 r^4}{4g} \Rightarrow \end{aligned}$$

$$h = \frac{V - (\pi \omega^2 r^4)/(4g)}{\pi r^2} = \frac{4gV - \pi \omega^2 r^4}{4\pi g r^2}.$$

(b) The surface touches the bottom when $h = 0 \Rightarrow 4gV - \pi\omega^2 r^4 = 0 \Rightarrow \omega^2 = \frac{4gV}{\pi r^4} \Rightarrow \omega = \frac{2\sqrt{gV}}{\sqrt{\pi r^2}}$.

To spill over the top, $y(r) > L \Leftrightarrow$

$$L < h + \frac{\omega^2 r^2}{2g} = \frac{4gV - \pi\omega^2 r^4}{4\pi g r^2} + \frac{\omega^2 r^2}{2g} = \frac{4gV}{4\pi g r^2} - \frac{\pi\omega^2 r^2}{4\pi g r^2} + \frac{\omega^2 r^2}{2g}$$

$$= \frac{V}{\pi r^2} - \frac{\omega^2 r^2}{4g} + \frac{\omega^2 r^2}{2g} = \frac{V}{\pi r^2} + \frac{\omega^2 r^2}{4g} \Leftrightarrow$$

$$\frac{\omega^2 r^2}{4g} > L - \frac{V}{\pi r^2} = \frac{\pi r^2 L - V}{\pi r^2} \Leftrightarrow \omega^2 > \frac{4g(\pi r^2 L - V)}{\pi r^4}. \text{ So for spillage, the angular speed should}$$

$$\text{be } \omega > \frac{2\sqrt{g(\pi r^2 L - V)}}{r^2 \sqrt{\pi}}.$$

(c) (i) Here we have $r = 2$, $L = 7$, $h = 7 - 5 = 2$. When $x = 1$, $y = 7 - 4 = 3$. Therefore, $3 = 2 + \frac{\omega^2 \cdot 1^2}{2 \cdot 32}$
 $\Rightarrow 1 = \frac{\omega^2}{2 \cdot 32} \Rightarrow \omega^2 = 64 \Rightarrow \omega = 8 \text{ rad/s. } V = \pi(2)(2)^2 + \frac{\pi \cdot 8^2 \cdot 2^4}{4g} = 8\pi + 8\pi = 16\pi \text{ ft}^2.$

(ii) At the wall, $x = 2$, so $y = 2 + \frac{8^2 \cdot 2^2}{2 \cdot 32} = 6$ and the surface is $7 - 6 = 1$ ft below the top of the tank.

13. We assume that P lies in the region of positive x . Since $y = x^3$ is an odd

function, this assumption will not affect the result of the calculation. Let

$P = (a, a^3)$. The slope of the tangent to the curve $y = x^3$ at P is $3a^2$, and so

the equation of the tangent is $y - a^3 = 3a^2(x - a) \Leftrightarrow y = 3a^2x - 2a^3$.

We solve this simultaneously with $y = x^3$ to find the other point of intersection:

$$x^3 = 3a^2x - 2a^3 \Leftrightarrow (x - a)^2(x + 2a) = 0. \text{ So } Q = (-2a, -8a^3) \text{ is}$$

the other point of intersection. The equation of the tangent at Q is

$$y - (-8a^3) = 12a^2[x - (-2a)] \Leftrightarrow y = 12a^2x + 16a^3. \text{ By symmetry,}$$

this tangent will intersect the curve again at $x = -2(-2a) = 4a$. The curve lies above the first tangent, and below

the second, so we are looking for a relationship between $A = \int_{-2a}^a [x^3 - (3a^2x - 2a^3)] dx$ and

$$B = \int_{-2a}^{4a} [(12a^2x + 16a^3) - x^3] dx. \text{ We calculate } A = \left[\frac{1}{4}x^4 - \frac{3}{2}a^2x^2 + 2a^3x \right]_{-2a}^a = \frac{3}{4}a^4 - (-6a^4) = \frac{27}{4}a^4,$$

$$\text{and } B = \left[6a^2x^2 + 16a^3x - \frac{1}{4}x^4 \right]_{-2a}^{4a} = 96a^4 - (-12a^4) = 108a^4. \text{ We see that } B = 16A = 2^4A. \text{ This is}$$

because our calculation of area B was essentially the same as that of area A , with a replaced by $-2a$, so if we

$$\text{replace } a \text{ with } -2a \text{ in our expression for } A, \text{ we get } \frac{27}{4}(-2a)^4 = 108a^4 = B.$$

14. (a) Place the round flat tortilla on an xy -coordinate system as

shown in the first figure. An equation of the circle is

$$x^2 + y^2 = 4^2 \text{ and the height of a cross-section is}$$

$$2\sqrt{16 - x^2}.$$

Now look at a cross-section with central angle θ_x as shown in the second figure (r is the radius of the circular cylinder).

The filled area $A(x)$ is equal to the area $A_1(x)$ of the sector minus the area $A_2(x)$ of the triangle.

$$\begin{aligned}
 A(x) &= A_1(x) - A_2(x) \\
 &= \frac{1}{2}r^2\theta_x - \frac{1}{2}r^2\sin\theta_x \quad [\text{area formulas from trigonometry}] \\
 &= \frac{1}{2}r(r\theta_x) - \frac{1}{2}r^2\sin\left(\frac{s}{r}\right) \quad [\text{arc length } s = r\theta_x \Rightarrow \theta_x = s/r] \\
 &= \frac{1}{2}r \cdot 2\sqrt{16-x^2} - \frac{1}{2}r^2\sin\left(\frac{2\sqrt{16-x^2}}{r}\right) \quad [s = 2\sqrt{16-x^2}] \\
 &= r\sqrt{16-x^2} - \frac{1}{2}r^2\sin\left(\frac{2}{r}\sqrt{16-x^2}\right) \quad (*)
 \end{aligned}$$

Note that the central angle θ_x will be small near the ends of the tortilla; that is, when $|x| \approx 4$. But near the center of the tortilla (when $|x| \approx 0$), the central angle θ_x may exceed 180° . Thus, the sine of θ_x will be negative and the second term in $(*)$ will be positive (actually adding area to the area of the sector). The volume of the taco can be found by integrating the cross-sectional areas from $x = -4$ to $x = 4$. Thus,

$$V(x) = \int_{-4}^4 A(x) dx = \int_{-4}^4 \left[r\sqrt{16-x^2} - \frac{1}{2}r^2\sin\left(\frac{2}{r}\sqrt{16-x^2}\right) \right] dx$$

(b) To find the value of r that maximizes the volume of the taco, we can define the function

$$V(r) = \int_{-4}^4 \left[r\sqrt{16-x^2} - \frac{1}{2}r^2\sin\left(\frac{2}{r}\sqrt{16-x^2}\right) \right] dx$$

The third figure shows a graph of $y = V(r)$ and $y = V'(r)$. The maximum volume of about 52.94 occurs when $r \approx 2.2912$.

7 INVERSE FUNCTIONS: Exponential, Logarithmic, and Inverse Trigonometric Functions

7.1 Inverse Functions

- (a) See Definition 1.
(b) It must pass the Horizontal Line Test.
- (a) $f^{-1}(y) = x \Leftrightarrow f(x) = y$ for any y in B . The domain of f^{-1} is B and the range of f^{-1} is A .
(b) See the steps in (5).
(c) Reflect the graph of f about the line $y = x$.
- f is not one-to-one because $2 \neq 6$, but $f(2) = 2.0 = f(6)$.
- f is one-to-one since for any two different domain values, there are different range values.
- No horizontal line intersects the graph of f more than once. Thus, by the Horizontal Line Test, f is one-to-one.
- The horizontal line $y = 0$ (the x -axis) intersects the graph of f in more than one point. Thus, by the Horizontal Line Test, f is not one-to-one.
- The horizontal line $y = 0$ (the x -axis) intersects the graph of f in more than one point. Thus, by the Horizontal Line Test, f is not one-to-one.
- No horizontal line intersects the graph of f more than once. Thus, by the Horizontal Line Test, f is one-to-one.
- The graph of $f(x) = \frac{1}{2}(x + 5)$ is a line with slope $\frac{1}{2}$. It passes the Horizontal Line Test, so f is one-to-one.
Algebraic solution: If $x_1 \neq x_2$, then $x_1 + 5 \neq x_2 + 5 \Rightarrow \frac{1}{2}(x_1 + 5) \neq \frac{1}{2}(x_2 + 5) \Rightarrow f(x_1) \neq f(x_2)$, so f is one-to-one.
- The graph of $f(x) = 1 + 4x - x^2$ is a parabola with axis of symmetry $x = -\frac{b}{2a} = -\frac{4}{2(-1)} = 2$. Pick any x -values equidistant from 2 to find two equal function values. For example, $f(1) = 4$ and $f(3) = 4$, so f is not 1-1.
- $x_1 \neq x_2 \Rightarrow \sqrt{x_1} \neq \sqrt{x_2} \Rightarrow g(x_1) \neq g(x_2)$, so g is 1-1.
- $g(x) = |x| \Rightarrow g(-1) = 1 = g(1)$, so g is not one-to-one.
- $h(x) = x^4 + 5 \Rightarrow h(1) = 6 = h(-1)$, so h is not 1-1.
- $x_1 \neq x_2 \Rightarrow x_1^4 \neq x_2^4$ [since $x \geq 0$] $\Rightarrow x_1^4 + 5 \neq x_2^4 + 5 \Rightarrow h(x_1) \neq h(x_2)$, so h is 1-1.
- A football will attain every height h up to its maximum height twice: once on the way up, and again on the way down. Thus, even if t_1 does not equal t_2 , $f(t_1)$ may equal $f(t_2)$, so f is not 1-1.
- f is not 1-1 because eventually we all stop growing and therefore, there are two times at which we have the same height.

17. f does not pass the Horizontal Line Test, so f is not 1-1.

18. f passes the Horizontal Line Test, so f is 1-1.

19. Since $f(2) = 9$ and f is 1-1, we know that $f^{-1}(9) = 2$. Remember, if the point $(2, 9)$ is on the graph of f , then the point $(9, 2)$ is on the graph of f^{-1} .
20. $f(x) = x + \cos x \Rightarrow f'(x) = 1 - \sin x \geq 0$, with equality only if $x = \frac{\pi}{2} + 2n\pi$. So f is increasing on $\mathbb{R}$, and hence, 1-1. By inspection, $f(0) = 0 + \cos 0 = 1$, so $f^{-1}(1) = 0$.
21. $h(x) = x + \sqrt{x} \Rightarrow h'(x) = 1 + 1/(2\sqrt{x}) > 0$ on $(0, \infty)$. So h is increasing and hence, 1-1. By inspection, $h(4) = 4 + \sqrt{4} = 6$, so $h^{-1}(6) = 4$.
22. (a) f is 1-1 because it passes the Horizontal Line Test.
 (b) Domain of $f = [-3, 3] = \text{Range of } f^{-1}$. Range of $f = [-2, 2] = \text{Domain of } f^{-1}$.
 (c) Since $f(-2) = 1$, $f^{-1}(1) = -2$.
23. We solve $C = \frac{5}{9}(F - 32)$ for F : $\frac{9}{5}C = F - 32 \Rightarrow F = \frac{9}{5}C + 32$. This gives us a formula for the inverse function, that is, the Fahrenheit temperature F as a function of the Celsius temperature C . $F \geq -459.67 \Rightarrow \frac{9}{5}C + 32 \geq -459.67 \Rightarrow \frac{9}{5}C \geq -491.67 \Rightarrow C \geq -273.15$, the domain of the inverse function.
24. $m = \frac{m_0}{\sqrt{1 - v^2/c^2}} \Rightarrow 1 - \frac{v^2}{c^2} = \frac{m_0^2}{m^2} \Rightarrow \frac{v^2}{c^2} = 1 - \frac{m_0^2}{m^2} \Rightarrow v^2 = c^2 \left(1 - \frac{m_0^2}{m^2}\right) \Rightarrow v = c \sqrt{1 - \frac{m_0^2}{m^2}}$. This formula gives us the speed v of the particle in terms of its mass m , that is, $v = f^{-1}(m)$.
25. $y = f(x) = 3 - 2x \Rightarrow 2x = 3 - y \Rightarrow x = \frac{3 - y}{2}$. Interchange x and y : $y = \frac{3 - x}{2}$. So $f^{-1}(x) = \frac{3 - x}{2}$.
26. $f(x) = \frac{4x - 1}{2x + 3} \Rightarrow y = \frac{4x - 1}{2x + 3} \Rightarrow y(2x + 3) = 4x - 1 \Rightarrow 2xy + 3y = 4x - 1 \Rightarrow 3y + 1 = 4x - 2xy \Rightarrow 3y + 1 = (4 - 2y)x \Rightarrow x = \frac{3y + 1}{4 - 2y}$. Interchange x and y : $y = \frac{3x + 1}{4 - 2x}$. So $f^{-1}(x) = \frac{3x + 1}{4 - 2x}$.
27. $f(x) = \sqrt{10 - 3x} \Rightarrow y = \sqrt{10 - 3x} \ (y \geq 0) \Rightarrow y^2 = 10 - 3x \Rightarrow 3x = 10 - y^2 \Rightarrow x = -\frac{1}{3}y^2 + \frac{10}{3}$. Interchange x and y : $y = -\frac{1}{3}x^2 + \frac{10}{3}$. So $f^{-1}(x) = -\frac{1}{3}x^2 + \frac{10}{3}$. Note that the domain of f^{-1} is $x \geq 0$.
28. $y = f(x) = 2x^3 + 3 \Rightarrow y - 3 = 2x^3 \Rightarrow \frac{y - 3}{2} = x^3 \Rightarrow x = \sqrt[3]{\frac{y - 3}{2}}$. Interchange x and y : $y = \sqrt[3]{\frac{x - 3}{2}}$. So $f^{-1}(x) = \sqrt[3]{\frac{x - 3}{2}}$.

29. For $f(x) = \frac{1 - \sqrt{x}}{1 + \sqrt{x}}$, the domain is $x \geq 0$. $f(0) = 1$ and as x increases, y decreases. As $x \rightarrow \infty$,

$$\frac{1 - \sqrt{x}}{1 + \sqrt{x}} \cdot \frac{1/\sqrt{x}}{1/\sqrt{x}} = \frac{1/\sqrt{x} - 1}{1/\sqrt{x} + 1} \rightarrow \frac{-1}{1} = -1, \text{ so the range of } f \text{ is } -1 < y \leq 1. \text{ Thus, the domain of } f^{-1} \text{ is } -1 < x \leq 1.$$

$$y = \frac{1 - \sqrt{x}}{1 + \sqrt{x}} \Rightarrow y(1 + \sqrt{x}) = 1 - \sqrt{x} \Rightarrow y + y\sqrt{x} = 1 - \sqrt{x} \Rightarrow \sqrt{x} + y\sqrt{x} = 1 - y \Rightarrow$$

$$\sqrt{x}(1 + y) = 1 - y \Rightarrow \sqrt{x} = \frac{1 - y}{1 + y} \Rightarrow x = \left(\frac{1 - y}{1 + y}\right)^2. \text{ Interchange } x \text{ and } y: y = \left(\frac{1 - x}{1 + x}\right)^2. \text{ So}$$

$$f^{-1}(x) = \left(\frac{1 - x}{1 + x}\right)^2 \text{ with } -1 < x \leq 1.$$

30. $y = f(x) = 2x^2 - 8x, x \geq 2 \Rightarrow 2x^2 - 8x - y = 0, x \geq 2 \Rightarrow$

$$x = \frac{8 + \sqrt{64 + 8y}}{4} \left[\begin{array}{l} \text{quadratic formula with} \\ a = 2, b = -8, \text{ and } c = -y \end{array} \right] = \frac{8 + 2\sqrt{16 + 2y}}{4} = 2 + \frac{1}{2}\sqrt{16 + 2y}. \text{ Interchange } x \text{ and}$$

$$y: y = 2 + \frac{1}{2}\sqrt{16 + 2x}. \text{ So } f^{-1}(x) = 2 + \frac{1}{2}\sqrt{16 + 2x}.$$

Alternate solution (by completing the square): $y = 2x^2 - 8x, x \geq 2 \Rightarrow x^2 - 4x = y/2, x \geq 2 \Rightarrow$

$$(x - 2)^2 = x^2 - 4x + 4 = \frac{y}{2} + 4 = \frac{y + 8}{2} = \frac{2y + 16}{4}, x \geq 2 \Rightarrow x - 2 = +\sqrt{\frac{2y + 16}{4}} \Rightarrow$$

$$x = 2 + \frac{1}{2}\sqrt{2y + 16}. \text{ Interchange } x \text{ and } y: y = 2 + \frac{1}{2}\sqrt{2x + 16}. \text{ So } f^{-1}(x) = 2 + \frac{1}{2}\sqrt{2x + 16}.$$

31. $y = f(x) = 1 - \frac{2}{x^2} \Rightarrow 1 - y = \frac{2}{x^2} \Rightarrow x^2 = \frac{2}{1 - y} \Rightarrow$

$$x = \sqrt{\frac{2}{1 - y}}, \text{ since } x > 0. \text{ Interchange } x \text{ and } y: y = \sqrt{\frac{2}{1 - x}}.$$

$$\text{So } f^{-1}(x) = \sqrt{\frac{2}{1 - x}}.$$

32. $y = f(x) = \sqrt{x^2 + 2x}, x > 0 \Rightarrow y > 0$ and $y^2 = x^2 + 2x \Rightarrow x^2 + 2x - y^2 = 0$. Now we use the quadratic formula:

$$x = \frac{-2 \pm \sqrt{2^2 - 4 \cdot 1 \cdot (-y^2)}}{2 \cdot 1} = -1 \pm \sqrt{1 + y^2}. \text{ But } x > 0, \text{ so the}$$

$$\text{negative root is inadmissible. Interchange } x \text{ and } y: y = -1 + \sqrt{1 + x^2}.$$

$$\text{So } f^{-1}(x) = -1 + \sqrt{1 + x^2}, x > 0.$$

33. The function f is one-to-one, so its inverse exists and the graph of its inverse can be obtained by reflecting the graph of f about the line $y = x$.

34. The function f is one-to-one, so its inverse exists and the graph of its inverse can be obtained by reflecting the graph of f about the line $y = x$. For the graph of $1/f$, the y -coordinates are simply the reciprocals of f . For example, if $f(5) = 9$, then $1/f(5) = \frac{1}{9}$. If we draw the horizontal line $y = 1$, we see that the only place where the graphs intersect is on that line.

35. (a) $x_1 \neq x_2 \Rightarrow x_1^3 \neq x_2^3 \Rightarrow f(x_1) \neq f(x_2)$, so f is one-to-one.

(b) $f'(x) = 3x^2$ and $f(2) = 8 \Rightarrow g(8) = 2$, so $g'(8) = 1/f'(g(8)) = 1/f'(2) = \frac{1}{12}$.

(c) $y = x^3 \Rightarrow x = y^{1/3}$. Interchanging x and y gives $y = x^{1/3}$, (e)

so $f^{-1}(x) = x^{1/3}$. Domain(g) = range(f) = $\mathbb{R}$.

Range(g) = domain(f) = $\mathbb{R}$.

(d) $g(x) = x^{1/3} \Rightarrow g'(x) = \frac{1}{3}x^{-2/3} \Rightarrow g'(8) = \frac{1}{3}\left(\frac{1}{4}\right) = \frac{1}{12}$

as in part (b).

36. (a) $x_1 \neq x_2 \Rightarrow x_1 - 2 \neq x_2 - 2 \Rightarrow \sqrt{x_1 - 2} \neq \sqrt{x_2 - 2} \Rightarrow f(x_1) \neq f(x_2)$, so f is 1-1.

(b) $f(6) = 2$, so $g(2) = 6$. Also $f'(x) = \frac{1}{2\sqrt{x-2}}$, so $g'(2) = \frac{1}{f'(g(2))} = \frac{1}{f'(6)} = \frac{1}{1/4} = 4$.

(c) $y = \sqrt{x-2} \Rightarrow y^2 = x-2 \Rightarrow x = y^2 + 2$. (e)

Interchange x and y : $y = x^2 + 2$. So $g(x) = x^2 + 2$.

Domain = $[0, \infty)$, range = $[2, \infty)$.

(d) $g(x) = x^2 + 2 \Rightarrow g'(x) = 2x \Rightarrow g'(2) = 4$.

37. (a) Since $x \geq 0$, $x_1 \neq x_2 \Rightarrow x_1^2 \neq x_2^2 \Rightarrow 9 - x_1^2 \neq 9 - x_2^2 \Rightarrow f(x_1) \neq f(x_2)$, so f is 1-1.

(b) $f'(x) = -2x$ and $f(1) = 8 \Rightarrow g(8) = 1$, so $g'(8) = \frac{1}{f'(g(8))} = \frac{1}{f'(1)} = \frac{1}{-2} = -\frac{1}{2}$.

(c) $y = 9 - x^2 \Rightarrow x^2 = 9 - y \Rightarrow x = \sqrt{9 - y}$. Interchange x (e)

and y : $y = \sqrt{9 - x}$, so $f^{-1}(x) = \sqrt{9 - x}$.

Domain(g) = range(f) = $[0, 9]$.

Range(g) = domain(f) = $[0, 3]$.

(d) $g'(x) = -1/(2\sqrt{9-x}) \Rightarrow g'(8) = -\frac{1}{2}$ as in part (b).

38. (a) $x_1 \neq x_2 \Rightarrow x_1 - 1 \neq x_2 - 1 \Rightarrow \frac{1}{x_1 - 1} \neq \frac{1}{x_2 - 1} \Rightarrow f(x_1) \neq f(x_2)$, so f is 1-1.

(b) $g(2) = \frac{3}{2}$ since $f(\frac{3}{2}) = 2$. Also $f'(x) = -1/(x-1)^2$, so $g'(2) = 1/f'(\frac{3}{2}) = \frac{1}{-4} = -\frac{1}{4}$.

(c) $y = 1/(x-1) \Rightarrow x-1 = 1/y \Rightarrow x = 1 + 1/y$. Interchange

x and y : $y = 1 + 1/x$. So $g(x) = 1 + 1/x$, $x > 0$ (since $y > 1$).

Domain = $(0, \infty)$, range = $(1, \infty)$.

(d) $g'(x) = -1/x^2$, so $g'(2) = -\frac{1}{4}$.

39. $f(0) = 1 \Rightarrow f^{-1}(1) = 0$, and $f(x) = x^3 + x + 1 \Rightarrow f'(x) = 3x^2 + 1$ and $f'(0) = 1$. Thus,

$$(f^{-1})'(1) = \frac{1}{f'(f^{-1}(1))} = \frac{1}{f'(0)} = \frac{1}{1} = 1.$$

40. $f(1) = 2 \Rightarrow f^{-1}(2) = 1$, and $f(x) = x^5 - x^3 + 2x \Rightarrow f'(x) = 5x^4 - 3x^2 + 2$ and $f'(1) = 4$. Thus,

$$(f^{-1})'(2) = \frac{1}{f'(f^{-1}(2))} = \frac{1}{f'(1)} = \frac{1}{4}.$$

41. $f(0) = 3 \Rightarrow f^{-1}(3) = 0$, and $f(x) = 3 + x^2 + \tan(\pi x/2) \Rightarrow f'(x) = 2x + \frac{\pi}{2} \sec^2(\pi x/2)$ and $f'(0) = \frac{\pi}{2} \cdot 1 = \frac{\pi}{2}$. Thus, $(f^{-1})'(3) = 1/f'(f^{-1}(3)) = 1/f'(0) = 2/\pi$.

42. $f(1) = 2 \Rightarrow f^{-1}(2) = 1$, and $f(x) = \sqrt{x^3 + x^2 + x + 1} \Rightarrow f'(x) = \frac{3x^2 + 2x + 1}{2\sqrt{x^3 + x^2 + x + 1}}$ and $f'(1) = \frac{3 + 2 + 1}{2\sqrt{1 + 1 + 1 + 1}} = \frac{3}{2}$. Thus, $(f^{-1})'(2) = 1/f'(f^{-1}(2)) = 1/f'(1) = \frac{2}{3}$.

43. $f(4) = 5 \Rightarrow g(5) = 4$. Thus, $g'(5) = \frac{1}{f'(g(5))} = \frac{1}{f'(4)} = \frac{1}{2/3} = \frac{3}{2}$.

44. $f(3) = 2 \Rightarrow g(2) = 3$. Thus, $g'(2) = \frac{1}{f'(g(2))} = \frac{1}{f'(3)} = 9$. Hence, $G(x) = \frac{1}{g(x)} \Rightarrow G'(x) = -\frac{g'(x)}{[g(x)]^2} \Rightarrow G'(2) = -\frac{g'(2)}{[g(2)]^2} = -\frac{9}{(3)^2} = -1$.

45. We see that the graph of $y = f(x) = \sqrt{x^3 + x^2 + x + 1}$ is increasing, so f is 1-1. Enter $x = \sqrt{y^3 + y^2 + y + 1}$ and use your CAS to solve the equation for y . Using Derive, we get two (irrelevant) solutions involving imaginary expressions, as well as one which can be simplified to the following:

$$y = f^{-1}(x) = -\frac{\sqrt[3]{4}}{6} (\sqrt[3]{D - 27x^2 + 20} - \sqrt[3]{D + 27x^2 - 20} + \sqrt[3]{2})$$

where $D = 3\sqrt{3}\sqrt{27x^4 - 40x^2 + 16}$. Maple and Mathematica each give two complex expressions and one real expression, and the real expression is equivalent to that given by Derive. For example, Maple's expression simplifies to $\frac{1}{6} \frac{M^{2/3} - 8 - 2M^{1/3}}{2M^{1/3}}$, where $M = 108x^2 + 12\sqrt{48 - 120x^2 + 81x^4} - 80$.

46. Since $\sin(2n\pi) = 0$, $h(x) = \sin x$ is not one-to-one. $h'(x) = \cos x > 0$ on $(-\frac{\pi}{2}, \frac{\pi}{2})$, so h is increasing and hence 1-1 on $[-\frac{\pi}{2}, \frac{\pi}{2}]$. Let $y = f^{-1}(x) = \sin^{-1} x$ so that $\sin y = x$. Differentiating $\sin y = x$ implicitly with respect to

x gives us $\cos y \frac{dy}{dx} = 1 \Rightarrow \frac{dy}{dx} = \frac{1}{\cos y}$. Now $\cos^2 y + \sin^2 y = 1 \Rightarrow \cos y = \pm \sqrt{1 - \sin^2 y}$, but since

$\cos y > 0$ on $(-\frac{\pi}{2}, \frac{\pi}{2})$, we have $\frac{dy}{dx} = \frac{1}{\sqrt{1 - \sin^2 y}} = \frac{1}{\sqrt{1 - x^2}}$.

47. (a) If the point (x, y) is on the graph of $y = f(x)$, then the point $(x - c, y)$ is that point shifted c units to the left. Since f is 1-1, the point (y, x) is on the graph of $y = f^{-1}(x)$ and the point corresponding to $(x - c, y)$ on the graph of f is $(y, x - c)$ on the graph of f^{-1} . Thus, the curve's reflection is shifted *down* the same number of units as the curve itself is shifted to the left. So an expression for the inverse function is $g^{-1}(x) = f^{-1}(x) - c$.
- (b) If we compress (or stretch) a curve horizontally, the curve's reflection in the line $y = x$ is compressed (or stretched) *vertically* by the same factor. Using this geometric principle, we see that the inverse of $h(x) = f(cx)$ can be expressed as $h^{-1}(x) = (1/c) f^{-1}(x)$.

48. (a) We know that $g'(x) = \frac{1}{f'(g(x))}$. Thus,

$$g''(x) = -\frac{f''(g(x)) \cdot g'(x)}{[f'(g(x))]^2} = -\frac{f''(g(x)) \cdot [1/f'(g(x))]}{[f'(g(x))]^2} = -\frac{f''(g(x))}{f'(g(x))[f'(g(x))]^2} = -\frac{f''(g(x))}{[f'(g(x))]^3}.$$

- (b) f is increasing $\Rightarrow f'(g(x)) > 0 \Rightarrow [f'(g(x))]^3 > 0$. f is concave upward $\Rightarrow f''(g(x)) > 0$. So

$$g''(x) = -\frac{f''(g(x))}{[f'(g(x))]^3} < 0, \text{ which implies that } g \text{ (} f \text{'s inverse) is concave downward.}$$

7.2 Exponential Functions and Their Derivatives

- (a) $f(x) = a^x$, $a > 0$

(b) $\mathbb{R}$

(c) $(0, \infty)$

(d) See Figures 6(c), 6(b), and 6(a), respectively.
- (a) The number e is the value of a such that the slope of the tangent line at $x = 0$ on the graph of $y = a^x$ is exactly 1.

(b) $e \approx 2.71828$

(c) $f(x) = e^x$
- All of these graphs approach 0 as $x \rightarrow -\infty$, all of them pass through the point $(0, 1)$, and all of them are increasing and approach ∞ as $x \rightarrow \infty$. The larger the base, the faster the function increases for $x > 0$, and the faster it approaches 0 as $x \rightarrow -\infty$.
- The graph of e^{-x} is the reflection of the graph of e^x about the y -axis, and the graph of 8^{-x} is the reflection of that of 8^x about the y -axis. The graph of 8^x increases more quickly than that of e^x for $x > 0$, and approaches 0 faster as $x \rightarrow -\infty$.

5. The functions with bases greater than 1 (3^x and 10^x) are increasing, while those with bases less than 1 ($(\frac{1}{3})^x$ and $(\frac{1}{10})^x$) are decreasing. The graph of $(\frac{1}{3})^x$ is the reflection of that of 3^x about the y -axis, and the graph of $(\frac{1}{10})^x$ is the reflection of that of 10^x about the y -axis. The graph of 10^x increases more quickly than that of 3^x for $x > 0$, and approaches 0 faster as $x \rightarrow -\infty$.

6. Each of the graphs approaches ∞ as $x \rightarrow -\infty$, and each approaches 0 as $x \rightarrow \infty$. The smaller the base, the faster the function grows as $x \rightarrow -\infty$, and the faster it approaches 0 as $x \rightarrow \infty$.

7. We start with the graph of $y = 4^x$ (Figure 3) and then shift 3 units downward. This shift doesn't affect the domain, but the range of $y = 4^x - 3$ is $(-3, \infty)$. There is a horizontal asymptote of $y = -3$.

8. We start with the graph of $y = 4^x$ (Figure 3) and then shift 3 units to the right. There is a horizontal asymptote of $y = 0$.

9. We start with the graph of $y = 2^x$ (Figure 3), reflect it about the y -axis, and then about the x -axis (or just rotate 180° to handle both reflections) to obtain the graph of $y = -2^{-x}$. In each graph, $y = 0$ is the horizontal asymptote.

10. We start with the graph of $y = e^x$ (Figure 12), vertically stretch by a factor of 2, and then shift 1 unit upward. There is a horizontal asymptote of $y = 1$.

11. We start with the graph of $y = e^x$ (Figure 12), reflect it about the x -axis, and then shift 3 units upward. Note the horizontal asymptote of $y = 3$.

12. We start with the graph of $y = e^x$ (Figure 12), reflect it about the y -axis, and then about the x -axis (or just rotate 180° to handle both reflections) to obtain the graph of $y = -e^{-x}$. Now shift this graph 1 unit upward, vertically stretch by a factor of 5, and then shift 2 units upward.

13. (a) To find the equation of the graph that results from shifting the graph of $y = e^x$ 2 units downward, we subtract 2 from the original function to get $y = e^x - 2$.
- (b) To find the equation of the graph that results from shifting the graph of $y = e^x$ 2 units to the right, we replace x with $x - 2$ in the original function to get $y = e^{(x-2)}$.
- (c) To find the equation of the graph that results from reflecting the graph of $y = e^x$ about the x -axis, we multiply the original function by -1 to get $y = -e^x$.
- (d) To find the equation of the graph that results from reflecting the graph of $y = e^x$ about the y -axis, we replace x with $-x$ in the original function to get $y = e^{-x}$.
- (e) To find the equation of the graph that results from reflecting the graph of $y = e^x$ about the x -axis and then about the y -axis, we first multiply the original function by -1 (to get $y = -e^x$) and then replace x with $-x$ in this equation to get $y = -e^{-x}$.
14. (a) This reflection consists of first reflecting the graph about the x -axis (giving the graph with equation $y = -e^x$) and then shifting this graph $2 \cdot 4 = 8$ units upward. So the equation is $y = -e^x + 8$.
- (b) This reflection consists of first reflecting the graph about the y -axis (giving the graph with equation $y = e^{-x}$) and then shifting this graph $2 \cdot 2 = 4$ units to the right. So the equation is $y = e^{-(x-4)}$.
15. (a) The denominator $1 + e^x$ is never equal to zero because $e^x > 0$, so the domain of $f(x) = 1/(1 + e^x)$ is $\mathbb{R}$.
- (b) $1 - e^x = 0 \Leftrightarrow e^x = 1 \Leftrightarrow x = 0$, so the domain of $f(x) = 1/(1 - e^x)$ is $(-\infty, 0) \cup (0, \infty)$.
16. (a) The sine and exponential functions have domain $\mathbb{R}$, so $g(t) = \sin(e^{-t})$ also has domain $\mathbb{R}$.
- (b) The function $g(t) = \sqrt{1 - 2^t}$ has domain $\{t \mid 1 - 2^t \geq 0\} = \{t \mid 2^t \leq 1\} = \{t \mid t \leq 0\} = (-\infty, 0]$.
17. Use $y = Ca^x$ with the points $(1, 6)$ and $(3, 24)$. $6 = Ca^1$ [$C = \frac{6}{a}$] and $24 = Ca^3 \Rightarrow 24 = \left(\frac{6}{a}\right)a^3 \Rightarrow 4 = a^2 \Rightarrow a = 2$ [since $a > 0$] and $C = \frac{6}{2} = 3$. The function is $f(x) = 3 \cdot 2^x$.

18. Given the y -intercept $(0, 2)$, we have $y = Ca^x = 2a^x$. Using the point $(2, \frac{2}{9})$ gives us $\frac{2}{9} = 2a^2 \Rightarrow \frac{1}{9} = a^2 \Rightarrow a = \frac{1}{3}$ [since $a > 0$]. The function is $f(x) = 2(\frac{1}{3})^x$ or $f(x) = 2(3)^{-x}$.
19. $2 \text{ ft} = 24 \text{ in}$, $f(24) = 24^2 \text{ in} = 576 \text{ in} = 48 \text{ ft}$. $g(24) = 2^{24} \text{ in} = 2^{24}/(12 \cdot 5280) \text{ mi} \approx 265 \text{ mi}$
20. We see from the graphs that for x less than about 1.8, $g(x) = 5^x > f(x) = x^5$, and then near the point $(1.8, 17.1)$ the curves intersect. Then $f(x) > g(x)$ from $x \approx 1.8$ until $x = 5$. At $(5, 3125)$ there is another point of intersection, and for $x > 5$ we see that $g(x) > f(x)$. In fact, g increases much more rapidly than f beyond that point.

21. The graph of g finally surpasses that of f at $x \approx 35.8$.

22. We graph $y = e^x$ and $y = 1,000,000,000$ and determine where $e^x = 1 \times 10^9$. This seems to be true at $x \approx 20.723$, so $e^x > 1 \times 10^9$ for $x > 20.723$.

23. $\lim_{x \rightarrow \infty} (1.001)^x = \infty$ by (3), since $1.001 > 1$.
24. Let $t = -x^2$. As $x \rightarrow \infty$, $t \rightarrow -\infty$. So $\lim_{x \rightarrow \infty} e^{-x^2} = \lim_{t \rightarrow -\infty} e^t = 0$ by (11).
25. Divide numerator and denominator by e^{3x} : $\lim_{x \rightarrow \infty} \frac{e^{3x} - e^{-3x}}{e^{3x} + e^{-3x}} = \lim_{x \rightarrow \infty} \frac{1 - e^{-6x}}{1 + e^{-6x}} = \frac{1 - 0}{1 + 0} = 1$
26. If we let $t = \tan x$, then as $x \rightarrow (\pi/2)^+$, $t \rightarrow -\infty$. Thus, $\lim_{x \rightarrow (\pi/2)^+} e^{\tan x} = \lim_{t \rightarrow -\infty} e^t = 0$.
27. Let $t = 3/(2-x)$. As $x \rightarrow 2^+$, $t \rightarrow -\infty$. So $\lim_{x \rightarrow 2^+} e^{3/(2-x)} = \lim_{t \rightarrow -\infty} e^t = 0$ by (11).

28. Let $t = 3/(2 - x)$. As $x \rightarrow 2^-$, $t \rightarrow \infty$. So $\lim_{x \rightarrow 2^-} e^{3/(2-x)} = \lim_{t \rightarrow \infty} e^t = \infty$ by (11).

29. By the Product Rule, $f(x) = x^2 e^x \Rightarrow f'(x) = x^2 \frac{d}{dx}(e^x) + e^x \frac{d}{dx}(x^2) = x^2 e^x + e^x(2x) = xe^x(x + 2)$.

30. By the Quotient Rule, $y = \frac{e^x}{1+x} \Rightarrow y' = \frac{(1+x)e^x - e^x(1)}{(1+x)^2} = \frac{e^x + xe^x - e^x}{(x+1)^2} = \frac{xe^x}{(x+1)^2}$.

31. By (10), $y = e^{ax^3} \Rightarrow y' = e^{ax^3} \frac{d}{dx}(ax^3) = 3ax^2 e^{ax^3}$.

32. $y = e^u(\cos u + cu) \Rightarrow y' = e^u(-\sin u + c) + (\cos u + cu)e^u = e^u(\cos u - \sin u + cu + c)$

33. $f(u) = e^{1/u} \Rightarrow f'(u) = e^{1/u} \cdot \frac{d}{du}\left(\frac{1}{u}\right) = e^{1/u} \left(\frac{-1}{u^2}\right) = \left(\frac{-1}{u^2}\right) e^{1/u}$

34. By the Product Rule, $g(x) = \sqrt{x} e^x = x^{1/2} e^x \Rightarrow g'(x) = x^{1/2}(e^x) + e^x\left(\frac{1}{2}x^{-1/2}\right) = \frac{1}{2}x^{-1/2}e^x(2x + 1)$.

35. By (10), $F(t) = e^{t \sin 2t} \Rightarrow$
 $F'(t) = e^{t \sin 2t}(t \sin 2t)' = e^{t \sin 2t}(t \cdot 2 \cos 2t + \sin 2t \cdot 1) = e^{t \sin 2t}(2t \cos 2t + \sin 2t)$

36. $y = e^{k \tan \sqrt{x}} \Rightarrow y' = e^{k \tan \sqrt{x}} \cdot \frac{d}{dx}(k \tan \sqrt{x}) = e^{k \tan \sqrt{x}} \left(k \sec^2 \sqrt{x} \cdot \frac{1}{2}x^{-1/2}\right) = \frac{k \sec^2 \sqrt{x}}{2\sqrt{x}} e^{k \tan \sqrt{x}}$

37. $y = \sqrt{1 + 2e^{3x}} \Rightarrow y' = \frac{1}{2}(1 + 2e^{3x})^{-1/2} \frac{d}{dx}(1 + 2e^{3x}) = \frac{1}{2\sqrt{1 + 2e^{3x}}}(2e^{3x} \cdot 3) = \frac{3e^{3x}}{\sqrt{1 + 2e^{3x}}}$

38. $y = \cos(e^{\pi x}) \Rightarrow y' = -\sin(e^{\pi x}) \cdot e^{\pi x} \cdot \pi = -\pi e^{\pi x} \sin(e^{\pi x})$

39. $y = e^{e^x} \Rightarrow y' = e^{e^x} \cdot \frac{d}{dx}(e^x) = e^{e^x} \cdot e^x$ or e^{e^x+x}

40. $y = \sqrt{1 + xe^{-2x}} \Rightarrow y' = \frac{1}{2}(1 + xe^{-2x})^{-1/2} [x(-2e^{-2x}) + e^{-2x}] = \frac{e^{-2x}(-2x + 1)}{2\sqrt{1 + xe^{-2x}}}$

41. By the Quotient Rule, $y = \frac{ae^x + b}{ce^x + d} \Rightarrow$
 $y' = \frac{(ce^x + d)(ae^x) - (ae^x + b)(ce^x)}{(ce^x + d)^2} = \frac{(ace^x + ad - ace^x - bc)e^x}{(ce^x + d)^2} = \frac{(ad - bc)e^x}{(ce^x + d)^2}$

42. $y = \frac{e^x + e^{-x}}{e^x - e^{-x}} \Rightarrow y' = \frac{(e^x - e^{-x})(e^x - e^{-x}) - (e^x + e^{-x})(e^x + e^{-x})}{(e^x - e^{-x})^2}$
 $= \frac{(e^{2x} - 2 + e^{-2x}) - (e^{2x} + 2 + e^{-2x})}{(e^x - e^{-x})^2} = -\frac{4}{(e^x - e^{-x})^2}$

43. $y = e^{2x} \cos \pi x \Rightarrow y' = e^{2x}(-\pi \sin \pi x) + (\cos \pi x)(2e^{2x}) = e^{2x}(2 \cos \pi x - \pi \sin \pi x)$.

At $(0, 1)$, $y' = 1(2 - 0) = 2$, so an equation of the tangent line is $y - 1 = 2(x - 0)$, or $y = 2x + 1$.

44. $y = \frac{e^x}{x} \Rightarrow y' = \frac{x \cdot e^x - e^x \cdot 1}{x^2} = \frac{e^x(x - 1)}{x^2}$. At $(1, e)$, $y' = 0$, and an equation of the tangent line is
 $y - e = 0(x - 1)$, or $y = e$.

45. $\frac{d}{dx}(e^{x^2 y}) = \frac{d}{dx}(x + y) \Rightarrow e^{x^2 y}(x^2 y' + y \cdot 2x) = 1 + y' \Rightarrow x^2 e^{x^2 y} y' + 2xy e^{x^2 y} = 1 + y' \Rightarrow$
 $x^2 e^{x^2 y} y' - y' = 1 - 2xy e^{x^2 y} \Rightarrow y'(x^2 e^{x^2 y} - 1) = 1 - 2xy e^{x^2 y} \Rightarrow y' = \frac{1 - 2xy e^{x^2 y}}{x^2 e^{x^2 y} - 1}$

$$46. xe^y + ye^x = 1 \Rightarrow xe^y y' + e^y \cdot 1 + ye^x + e^x y' = 0 \Rightarrow y'(xe^y + e^x) = -e^y - ye^x \Rightarrow$$

$$y' = -\frac{e^y + ye^x}{xe^y + e^x}. \text{ At } (0, 1), y' = -\frac{e + 1 \cdot 1}{0 + 1} = -(e + 1), \text{ so an equation for the tangent line is}$$

$$y - 1 = -(e + 1)(x - 0), \text{ or } y = -(e + 1)x + 1.$$

$$47. y = e^x + e^{-x/2} \Rightarrow y' = e^x - \frac{1}{2}e^{-x/2} \Rightarrow y'' = e^x + \frac{1}{4}e^{-x/2}, \text{ so}$$

$$2y'' - y' - y = 2\left(e^x + \frac{1}{4}e^{-x/2}\right) - \left(e^x - \frac{1}{2}e^{-x/2}\right) - \left(e^x + e^{-x/2}\right) = 0.$$

$$48. y = Ae^{-x} + Bxe^{-x} \Rightarrow y' = -Ae^{-x} + Be^{-x} - Bxe^{-x} = (B - A)e^{-x} - Bxe^{-x} \Rightarrow$$

$$y'' = (A - B)e^{-x} - Be^{-x} + Bxe^{-x} = (A - 2B)e^{-x} + Bxe^{-x}, \text{ so}$$

$$y'' + 2y' + y = (A - 2B)e^{-x} + Bxe^{-x} + 2[(B - A)e^{-x} - Bxe^{-x}] + Ae^{-x} + Bxe^{-x} = 0.$$

$$49. y = e^{rx} \Rightarrow y' = re^{rx} \Rightarrow y'' = r^2 e^{rx}, \text{ so if } y = e^{rx} \text{ satisfies the differential equation } y'' + 6y' + 8y = 0,$$

then $r^2 e^{rx} + 6re^{rx} + 8e^{rx} = 0$; that is, $e^{rx}(r^2 + 6r + 8) = 0$. Since $e^{rx} > 0$ for all x , we must have

$$r^2 + 6r + 8 = 0, \text{ or } (r + 2)(r + 4) = 0, \text{ so } r = -2 \text{ or } -4.$$

$$50. y = e^{\lambda x} \Rightarrow y' = \lambda e^{\lambda x} \Rightarrow y'' = \lambda^2 e^{\lambda x}. \text{ Thus, } y + y' = y'' \Leftrightarrow e^{\lambda x} + \lambda e^{\lambda x} = \lambda^2 e^{\lambda x} \Leftrightarrow$$

$$e^{\lambda x}(\lambda^2 - \lambda - 1) = 0 \Leftrightarrow \lambda = \frac{1 \pm \sqrt{5}}{2}, \text{ since } e^{\lambda x} \neq 0.$$

$$51. f(x) = e^{2x} \Rightarrow f'(x) = 2e^{2x} \Rightarrow f''(x) = 2 \cdot 2e^{2x} = 2^2 e^{2x} \Rightarrow$$

$$f'''(x) = 2^2 \cdot 2e^{2x} = 2^3 e^{2x} \Rightarrow \dots \Rightarrow f^{(n)}(x) = 2^n e^{2x}$$

$$52. f(x) = xe^{-x} \Rightarrow f'(x) = x(-e^{-x}) + e^{-x} = (1 - x)e^{-x} \Rightarrow$$

$$f''(x) = (1 - x)(-e^{-x}) + e^{-x}(-1) = (x - 2)e^{-x} \Rightarrow f'''(x) = (x - 2)(-e^{-x}) + e^{-x} = (3 - x)e^{-x} \Rightarrow$$

$$f^{(4)}(x) = (3 - x)(-e^{-x}) + e^{-x}(-1) = (x - 4)e^{-x} \Rightarrow \dots \Rightarrow f^{(n)}(x) = (-1)^n(x - n)e^{-x}.$$

$$\text{So } D^{1000}xe^{-x} = (x - 1000)e^{-x}.$$

53. (a) $f(x) = e^x + x$ is continuous on $\mathbb{R}$ and $f(-1) = e^{-1} - 1 < 0 < 1 = f(0)$, so by the Intermediate Value Theorem, $e^x + x = 0$ has a root in $(-1, 0)$.

$$(b) f(x) = e^x + x \Rightarrow f'(x) = e^x + 1, \text{ so } x_{n+1} = x_n - \frac{e^{x_n} + x_n}{e^{x_n} + 1}. \text{ Using } x_1 = -0.5, \text{ we get}$$

$$x_2 \approx -0.566311, x_3 \approx -0.567143 \approx x_4, \text{ so the root is } -0.567143 \text{ to six decimal places.}$$

54.

From the graph, it appears that the curves intersect at about $x \approx 1.2$ or 1.3 .

We use Newton's Method with $f(x) = x^3 + x - 3 - e^{-x^2}$, so

$$f'(x) = 3x^2 + 1 + 2xe^{-x^2}, \text{ and the formula is}$$

$$x_{n+1} = x_n - f(x_n)/f'(x_n). \text{ We take } x_1 = 1.2, \text{ and the formula gives}$$

$x_2 \approx 1.252462, x_3 \approx 1.251045, \text{ and } x_4 \approx x_5 \approx 1.251044. \text{ So the root of the equation, correct to six decimal places, is } x = 1.251044.$

55. (a) $m(t) = 24 \cdot 2^{-t/25} \Rightarrow$

$$m(40) = 24 \cdot 2^{-40/25} \approx 7.92 \text{ mg}$$

$$\begin{aligned} \text{(b) } m'(t) &= 24 \frac{d}{dt} \left(2^{-t/25} \right) \\ &\approx 24(0.69) 2^{-t/25} \frac{d}{dt} \left(-\frac{t}{25} \right) \quad [(7) \text{ and } (10)] \\ &= 24(0.69) \left(-\frac{1}{25} \right) 2^{-t/25} \end{aligned}$$

$$\text{so } m'(40) \approx -\frac{24}{25}(0.69) 2^{-40/25} \approx -0.22 \text{ mg/yr.}$$

(c)

From the graph, we can determine that $m(t) = 5 \Rightarrow t \approx 56.6$ yr.

From the graph, we estimate that the most rapid increase in the percentage of households in the United States with at least one VCR occurs at about $t = 8$. To maximize the first derivative, we need to determine the values for which the second derivative is 0. We'll use

$V(t) = \frac{a}{1 + be^{ct}}$, and substitute $a = 85$, $b = 53$, and $c = -0.5$ later.

$$V'(t) = -\frac{a(bce^{ct})}{(1 + be^{ct})^2} \quad [\text{by the Reciprocal Rule}] \quad \text{and}$$

$$\begin{aligned} V''(t) &= -abc \cdot \frac{(1 + be^{ct})^2 \cdot ce^{ct} - e^{ct} \cdot 2(1 + be^{ct}) \cdot bce^{ct}}{[(1 + be^{ct})^2]^2} \\ &= \frac{-abc \cdot ce^{ct}(1 + be^{ct})[(1 + be^{ct}) - 2be^{ct}]}{(1 + be^{ct})^4} = \frac{-abc^2 e^{ct}(1 - be^{ct})}{(1 + be^{ct})^3} \end{aligned}$$

So $V''(t) = 0 \Leftrightarrow 1 = be^{ct} \Leftrightarrow e^{ct} = 1/b$. Now graph $y = e^{-0.5t}$ and $y = \frac{1}{53}$. These graphs intersect at $t \approx 7.94$ years, which corresponds to roughly midyear 1988. [Alternatively, we could use the rootfinder on a calculator to solve $e^{-0.5t} = \frac{1}{53}$. Or, if you have already studied logarithms, you can solve $e^{ct} = 1/b$ as follows:

$$ct = \ln(1/b) \Leftrightarrow t = (1/c) \ln(1/b) = -2 \ln \frac{1}{53} \approx 7.94 \text{ years.}$$

57. (a) $\lim_{t \rightarrow \infty} p(t) = \lim_{t \rightarrow \infty} \frac{1}{1 + ae^{-kt}} = \frac{1}{1 + a \cdot 0} = 1$, since $k > 0 \Rightarrow -kt \rightarrow -\infty \Rightarrow e^{-kt} \rightarrow 0$.

(b) $p(t) = (1 + ae^{-kt})^{-1} \Rightarrow \frac{dp}{dt} = -(1 + ae^{-kt})^{-2} (-kae^{-kt}) = \frac{kae^{-kt}}{(1 + ae^{-kt})^2}$

From the graph of $p(t) = (1 + 10e^{-0.5t})^{-1}$, it seems that $p(t) = 0.8$ (indicating that 80% of the population has heard the rumor) when $t \approx 7.4$ hours.

58. (a)

The displacement function is squeezed between the other two functions. This is because $-1 \leq \sin 4t \leq 1 \Rightarrow -8e^{-t/2} \leq 8e^{-t/2} \sin 4t \leq 8e^{-t/2}$.

(b) The maximum value of the displacement is about 6.6 cm, occurring at $t \approx 0.36$ s. It occurs just before the graph of the displacement function touches the graph of $8e^{-t/2}$ (when $t = \frac{\pi}{8} \approx 0.39$).

(c) The velocity of the object is the derivative of its displacement function, that is,

$$\frac{d}{dt} (8e^{-t/2} \sin 4t) = 8 \left[e^{-t/2} \cos 4t(4) + \sin 4t \left(-\frac{1}{2}\right) e^{-t/2} \right].$$

If the displacement is zero, then we must have $\sin 4t = 0$ (since the exponential term in the displacement function is always positive). The first time that $\sin 4t = 0$ after $t = 0$ occurs at $t = \frac{\pi}{4}$. Substituting this into our expression for the velocity, and noting that the second term vanishes, we

$$\text{get } v\left(\frac{\pi}{4}\right) = 8e^{-\pi/8} \cos\left(4 \cdot \frac{\pi}{4}\right) \cdot 4 = -32e^{-\pi/8} \approx -21.6 \text{ cm/s.}$$

(d) 10

The graph indicates that the displacement is less than 2 cm from equilibrium whenever t is larger than about 2.8.

59. (a) Using a calculator or CAS, we obtain the model $Q = ab^t$ with $a = 100.0124369$ and $b = 0.000045145933$. We can change this model to one with base e and exponent $\ln b$ [$b^t = e^{t \ln b}$ from precalculus mathematics or from Section 7.3]: $Q = ae^{t \ln b} = 100.012437e^{-10.005531t}$.

(b) Use $Q'(t) = ab^t \ln b$ or the calculator command `nDeriv(Y1, X, .04)` with $Y1 = ab^x$ to get $Q'(0.04) \approx -670.63 \mu\text{A}$. The result of Example 2 in Section 2.1 was $-670 \mu\text{A}$.

60. (a) $P = ab^t$ with $a = 4.502714 \times 10^{-20}$ and $b = 1.029953851$, where P is measured in thousands of people. The fit appears to be very good.

(b) For 1800: $m_1 = \frac{5308 - 3929}{1800 - 1790} = 137.9$, $m_2 = \frac{7240 - 5308}{1810 - 1800} = 193.2$.

So $P'(1800) \approx (m_1 + m_2)/2 = 165.55$ thousand people/year.

For 1850: $m_1 = \frac{23,192 - 17,063}{1850 - 1840} = 612.9$, $m_2 = \frac{31,443 - 23,192}{1860 - 1850} = 825.1$.

So $P'(1850) \approx (m_1 + m_2)/2 = 719$ thousand people/year.

(c) Use the calculator command `nDeriv(Y1, X, year)` with $Y1 = ab^x$ to get

$P'(1800) \approx 156.85$ and $P'(1850) \approx 686.07$. These estimates are somewhat less than the ones in part (b).

(d) $P(1870) \approx 41,946.56$. The difference of 3.4 million people is most likely due to the Civil War (1861–1865).

61. $f(x) = x - e^x \Rightarrow f'(x) = 1 - e^x = 0 \Leftrightarrow e^x = 1 \Leftrightarrow x = 0$. Now $f'(x) > 0$ for all $x < 0$ and $f'(x) < 0$ for all $x > 0$, so the absolute maximum value is $f(0) = 0 - 1 = -1$.

62. $g(x) = \frac{e^x}{x} \Rightarrow g'(x) = \frac{xe^x - e^x}{x^2} = 0 \Leftrightarrow e^x(x - 1) = 0 \Rightarrow x = 1$. Now $g'(x) > 0 \Leftrightarrow \frac{xe^x - e^x}{x^2} > 0 \Leftrightarrow x - 1 > 0 \Leftrightarrow x > 1$ and $g'(x) < 0 \Leftrightarrow \frac{xe^x - e^x}{x^2} < 0 \Leftrightarrow x - 1 < 0 \Leftrightarrow x < 1$. Thus there is an absolute minimum value of $g(1) = e$ at $x = 1$.

63. (a) $f(x) = xe^x \Rightarrow f'(x) = e^x + xe^x = e^x(1 + x) > 0 \Leftrightarrow 1 + x > 0 \Leftrightarrow x > -1$, so f is increasing on $(-1, \infty)$ and decreasing on $(-\infty, -1)$.

(b) $f''(x) = e^x(1 + x) + e^x = e^x(2 + x) > 0 \Leftrightarrow 2 + x > 0 \Leftrightarrow x > -2$, so f is CU on $(-2, \infty)$ and CD on $(-\infty, -2)$.

(c) f has an inflection point at $(-2, -2e^{-2})$.

64. (a) $f(x) = x^2e^x \Rightarrow f'(x) = 2xe^x + x^2e^x = (x^2 + 2x)e^x$. $f'(x) > 0 \Leftrightarrow x(x + 2) > 0 \Leftrightarrow x < -2$ or $x > 0$, $f'(x) < 0 \Leftrightarrow -2 < x < 0$, so f is increasing on $(-\infty, -2)$ and $(0, \infty)$ and decreasing on $(-2, 0)$.

(b) $f''(x) = (2x + 2)e^x + (x^2 + 2x)e^x = (x^2 + 4x + 2)e^x = 0 \Leftrightarrow x^2 + 4x + 2 = 0 \Leftrightarrow x = -2 \pm \sqrt{2}$
 $f''(x) > 0$ when $x > -2 + \sqrt{2}$ or $x < -2 - \sqrt{2}$, so f is CU on $(-\infty, -2 - \sqrt{2})$ and $(-2 + \sqrt{2}, \infty)$ and CD on $(-2 - \sqrt{2}, -2 + \sqrt{2})$.

(c) f has inflection points at $(-2 + \sqrt{2}, (6 - 4\sqrt{2})e^{-2+\sqrt{2}})$ and $(-2 - \sqrt{2}, (6 + 4\sqrt{2})e^{-2-\sqrt{2}})$.

65. $y = f(x) = e^{-1/(x+1)}$ A. $D = \{x \mid x \neq -1\} = (-\infty, -1) \cup (-1, \infty)$ B. No x -intercept;

y -intercept $= f(0) = e^{-1}$ C. No symmetry D. $\lim_{x \rightarrow \pm\infty} e^{-1/(x+1)} = 1$ since $-1/(x+1) \rightarrow 0$, so $y = 1$ is

a HA. $\lim_{x \rightarrow -1^+} e^{-1/(x+1)} = 0$ since $-1/(x+1) \rightarrow -\infty$, $\lim_{x \rightarrow -1^-} e^{-1/(x+1)} = \infty$ since $-1/(x+1) \rightarrow \infty$, so

$x = -1$ is a VA. E. $f'(x) = e^{-1/(x+1)}/(x+1)^2 \Rightarrow f'(x) > 0$ for all x except -1 , so

f is increasing on $(-\infty, -1)$ and $(-1, \infty)$. F. No extreme values H.

$$\text{G. } f''(x) = \frac{e^{-1/(x+1)}}{(x+1)^4} + \frac{e^{-1/(x+1)}(-2)}{(x+1)^3} = -\frac{e^{-1/(x+1)}(2x+1)}{(x+1)^4}$$

$$\Rightarrow f''(x) > 0 \Leftrightarrow 2x + 1 < 0 \Leftrightarrow x < -\frac{1}{2}, \text{ so } f \text{ is CU on}$$

$(-\infty, -1)$ and $(-1, -\frac{1}{2})$, and CD on $(-\frac{1}{2}, \infty)$. f has an IP

at $(-\frac{1}{2}, e^{-2})$.

66. $y = f(x) = e^{2x} - e^x$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$;

x -intercepts: $f(x) = 0 \Rightarrow e^{2x} = e^x \Rightarrow e^x = 1 \Rightarrow x = 0$.

C. No symmetry D. $\lim_{x \rightarrow -\infty} e^{2x} - e^x = 0$, so $y = 0$ is a HA. No VA.

E. $f'(x) = 2e^{2x} - e^x = e^x(2e^x - 1)$, so $f'(x) > 0 \Leftrightarrow e^x > \frac{1}{2}$ (*)

$\Leftrightarrow x > \ln \frac{1}{2} = -\ln 2$ and $f'(x) < 0 \Leftrightarrow e^x < \frac{1}{2} \Leftrightarrow x < \ln \frac{1}{2}$, so

f is decreasing on $(-\infty, \ln \frac{1}{2})$ and increasing on $(\ln \frac{1}{2}, \infty)$. F. Local

minimum value $f(\ln \frac{1}{2}) = e^{2 \ln(1/2)} - e^{\ln(1/2)} = (\frac{1}{2})^2 - \frac{1}{2} = -\frac{1}{4}$

G. $f''(x) = 4e^{2x} - e^x = e^x(4e^x - 1)$, so $f''(x) > 0 \Leftrightarrow$

$e^x > \frac{1}{4} \Leftrightarrow x > \ln \frac{1}{4}$ and $f''(x) < 0 \Leftrightarrow x < \ln \frac{1}{4}$.

Thus, f is CD on $(-\infty, \ln \frac{1}{4})$ and CU on $(\ln \frac{1}{4}, \infty)$. f has an IP at $(\ln \frac{1}{4}, (\frac{1}{4})^2 - \frac{1}{4}) = (\ln \frac{1}{4}, -\frac{3}{16})$.

(*) If you have not yet learned about logarithms, graph $y = e^x$ and $y = \frac{1}{2}$, find the point of intersection, and use decimal approximations for the rest of the solution.

H.

67. $y = f(x) = e^{3x} + e^{-2x}$ A. $D = \mathbb{R}$ B. y -intercept = $f(0) = 2$;

no x -intercept C. No symmetry D. No asymptotes

E. $f'(x) = 3e^{3x} - 2e^{-2x}$, so $f'(x) > 0 \Leftrightarrow 3e^{3x} > 2e^{-2x}$

[multiply by e^{2x}] $\Leftrightarrow e^{5x} > \frac{2}{3}$ (*) $\Leftrightarrow 5x > \ln \frac{2}{3} \Leftrightarrow$

$x > \frac{1}{5} \ln \frac{2}{3} \approx -0.081$. Similarly, $f'(x) < 0 \Leftrightarrow x < \frac{1}{5} \ln \frac{2}{3}$.

f is decreasing on $(-\infty, \frac{1}{5} \ln \frac{2}{3})$ and increasing on $(\frac{1}{5} \ln \frac{2}{3}, \infty)$.

F. Local minimum value $f(\frac{1}{5} \ln \frac{2}{3}) = (\frac{2}{3})^{3/5} + (\frac{2}{3})^{-2/5} \approx 1.96$; no local maximum.

G. $f''(x) = 9e^{3x} + 4e^{-2x}$, so $f''(x) > 0$ for all x , and f is CU on $(-\infty, \infty)$. No IP

(*) If you have not yet learned about logarithms, graph $y = e^{5x}$ and $y = \frac{2}{3}$, find the point of intersection, and use decimal approximations for the rest of the solution.

H.

68. The function $f(x) = e^{\cos x}$ is periodic

with period 2π , so we consider it only on the interval $[0, 2\pi]$. We see that it has

local maxima of about $f(0) \approx 2.72$ and

$f(2\pi) \approx 2.72$, and a local minimum of

about $f(3.14) \approx 0.37$. To find the exact

values, we calculate $f'(x) = -\sin x e^{\cos x}$. This is 0 when $-\sin x = 0 \Leftrightarrow x = 0, \pi$ or 2π (since we are only considering $x \in [0, 2\pi]$). Also $f'(x) > 0 \Leftrightarrow \sin x < 0 \Leftrightarrow 0 < x < \pi$. So $f(0) = f(2\pi) = e$

(both maxima) and $f(\pi) = e^{\cos \pi} = 1/e$ (minimum). To find the inflection points, we calculate and graph

$$f''(x) = \frac{d}{dx}(-\sin x e^{\cos x}) = -\cos x e^{\cos x} - \sin x(e^{\cos x})(-\sin x) = e^{\cos x}(\sin^2 x - \cos x).$$

From the graph of $f''(x)$, we see that f has inflection points at $x \approx 0.90$ and at $x \approx 5.38$. These x -coordinates correspond to inflection points $(0.90, 1.86)$ and $(5.38, 1.86)$.

69. $f(x) = e^{x^3-x} \rightarrow 0$ as $x \rightarrow -\infty$, and $f(x) \rightarrow \infty$ as $x \rightarrow \infty$. From the graph, it appears that f has a local minimum of about $f(0.58) = 0.68$, and a local maximum of about $f(-0.58) = 1.47$.

To find the exact values, we calculate

$$f'(x) = (3x^2 - 1)e^{x^3-x}, \text{ which is 0 when } 3x^2 - 1 = 0 \Leftrightarrow x = \pm \frac{1}{\sqrt{3}}. \text{ The negative root corresponds to the}$$

local maximum $f\left(-\frac{1}{\sqrt{3}}\right) = e^{(-1/\sqrt{3})^3 - (-1/\sqrt{3})} = e^{2\sqrt{3}/9}$, and the positive root corresponds to the local

minimum $f\left(\frac{1}{\sqrt{3}}\right) = e^{(1/\sqrt{3})^3 - (1/\sqrt{3})} = e^{-2\sqrt{3}/9}$. To estimate the inflection points, we calculate and graph

$$f''(x) = \frac{d}{dx}[(3x^2 - 1)e^{x^3-x}] = (3x^2 - 1)e^{x^3-x}(3x^2 - 1) + e^{x^3-x}(6x) = e^{x^3-x}(9x^4 - 6x^2 + 6x + 1).$$

From the graph, it appears that $f''(x)$ changes sign (and thus f has inflection points) at $x \approx -0.15$ and

$x \approx -1.09$. From the graph of f , we see that these x -values correspond to inflection points at about $(-0.15, 1.15)$ and $(-1.09, 0.82)$.

70. (a) As $|x| \rightarrow \infty$, $t = -x^2/(2\sigma^2) \rightarrow -\infty$, and $e^t \rightarrow 0$. The HA is $y = 0$. Since t takes on its maximum value at $x = 0$, so does e^t . Showing this result using derivatives, we have $f(x) = e^{-x^2/(2\sigma^2)} \Rightarrow$

$$f'(x) = e^{-x^2/(2\sigma^2)}(-x/\sigma^2). \quad f'(x) = 0 \Leftrightarrow x = 0. \text{ Because } f' \text{ changes from positive to negative at } x = 0, \quad f(0) = 1 \text{ is a local maximum. For inflection points, we find}$$

$$f''(x) = -\frac{1}{\sigma^2} \left[e^{-x^2/(2\sigma^2)} \cdot 1 + x e^{-x^2/(2\sigma^2)}(-x/\sigma^2) \right] = \frac{-1}{\sigma^2} e^{-x^2/(2\sigma^2)}(1 - x^2/\sigma^2).$$

$$f''(x) = 0 \Leftrightarrow x^2 = \sigma^2 \Leftrightarrow x = \pm\sigma. \quad f''(x) < 0 \Leftrightarrow x^2 < \sigma^2 \Leftrightarrow -\sigma < x < \sigma. \text{ So } f \text{ is CD on } (-\sigma, \sigma) \text{ and CU on } (-\infty, -\sigma) \text{ and } (\sigma, \infty). \text{ IP at } (\pm\sigma, e^{-1/2}).$$

(b) Since we have IP at $x = \pm\sigma$, the inflection points move away from the y -axis as σ increases.

(c)

From the graph, we see that as σ increases, the graph tends to spread out and there is more area between the curve and the x -axis.

71. Let $u = -3x$. Then $du = -3dx$, so

$$\int_0^5 e^{-3x} dx = -\frac{1}{3} \int_0^{-15} e^u du = -\frac{1}{3} [e^u]_0^{-15} = -\frac{1}{3} (e^{-15} - e^0) = \frac{1}{3} (1 - e^{-15}).$$

72. Let $u = -x^2$, so $du = -2x dx$. When $x = 0$, $u = 0$; when $x = 1$, $u = -1$. Thus,

$$\int_0^1 x e^{-x^2} dx = \int_0^{-1} e^u \left(-\frac{1}{2} du\right) = -\frac{1}{2} [e^u]_0^{-1} = -\frac{1}{2} (e^{-1} - e^0) = \frac{1}{2} (1 - 1/e).$$

73. Let $u = 1 + e^x$. Then $du = e^x dx$, so $\int e^x \sqrt{1 + e^x} dx = \int \sqrt{u} du = \frac{2}{3} u^{3/2} + C = \frac{2}{3} (1 + e^x)^{3/2} + C$.

74. Let $u = \tan x$. Then $du = \sec^2 x dx$, so $\int \sec^2 x e^{\tan x} dx = \int e^u du = e^u + C = e^{\tan x} + C$.

$$75. \int \frac{e^x + 1}{e^x} dx = \int (1 + e^{-x}) dx = x - e^{-x} + C$$

76. Let $u = \frac{1}{x}$. Then $du = -\frac{1}{x^2} dx$, so $\int \frac{e^{1/x}}{x^2} dx = -\int e^u du = -e^u + C = -e^{1/x} + C$.

77. Let $u = \sqrt{x}$. Then $du = \frac{1}{2\sqrt{x}} dx$, so $\int \frac{e^{\sqrt{x}}}{\sqrt{x}} dx = 2 \int e^u du = 2e^u + C = 2e^{\sqrt{x}} + C$.

78. Let $u = e^x$. Then $du = e^x dx$, so $\int e^x \sin(e^x) dx = \int \sin u du = -\cos u + C = -\cos(e^x) + C$.

79. Area $= \int_0^1 (e^{3x} - e^x) dx = [\frac{1}{3}e^{3x} - e^x]_0^1 = (\frac{1}{3}e^3 - e) - (\frac{1}{3} - 1) = \frac{1}{3}e^3 - e + \frac{2}{3} \approx 4.644$

80. $f''(x) = 3e^x + 5 \sin x \Rightarrow f'(x) = 3e^x - 5 \cos x + C \Rightarrow 2 = f'(0) = 3 - 5 + C \Rightarrow C = 4$, so
 $f'(x) = 3e^x - 5 \cos x + 4 \Rightarrow f(x) = 3e^x - 5 \sin x + 4x + D \Rightarrow 1 = f(0) = 3 + D \Rightarrow D = -2$,
 so $f(x) = 3e^x - 5 \sin x + 4x - 2$.

81. $V = \int_0^1 \pi (e^x)^2 dx = \pi \int_0^1 e^{2x} dx = \frac{1}{2} \pi [e^{2x}]_0^1 = \frac{\pi}{2} (e^2 - 1)$

82. $V = \int_0^1 2\pi x e^{-x^2} dx$. Let $u = x^2$. Thus $du = 2x dx$, so $V = \pi \int_0^1 e^{-u} du = \pi [-e^{-u}]_0^1 = \pi(1 - 1/e)$.

83. We use Theorem 7.1.7. Note that $f(0) = 3 + 0 + e^0 = 4$, so $f^{-1}(4) = 0$. Also $f'(x) = 1 + e^x$. Therefore,

$$(f^{-1})'(4) = \frac{1}{f'(f^{-1}(4))} = \frac{1}{f'(0)} = \frac{1}{1 + e^0} = \frac{1}{2}.$$

84. We recognize this limit as the definition of the derivative of the function $f(x) = e^{\sin x}$ at $x = \pi$, since it is of the form $\lim_{x \rightarrow \pi} \frac{f(x) - f(\pi)}{x - \pi}$. Therefore, the limit is equal to $f'(\pi) = (\cos \pi) e^{\sin \pi} = -1 \cdot e^0 = -1$.

85. (a) Let $f(x) = e^x - 1 - x$. Now $f(0) = e^0 - 1 - 0 = 0$, and for $x \geq 0$, we have $f'(x) = e^x - 1 \geq 0$. Now, since $f(0) = 0$ and f is increasing on $[0, \infty)$, $f(x) \geq 0$ for $x \geq 0 \Rightarrow e^x - 1 - x \geq 0 \Rightarrow e^x \geq 1 + x$.

(b) For $0 \leq x \leq 1$, $x^2 \leq x$, so $e^{x^2} \leq e^x$ [since e^x is increasing]. Hence [from (a)] $1 + x^2 \leq e^{x^2} \leq e^x$.

$$\text{So } \frac{4}{3} = \int_0^1 (1 + x^2) dx \leq \int_0^1 e^{x^2} dx \leq \int_0^1 e^x dx = e - 1 < e \Rightarrow \frac{4}{3} \leq \int_0^1 e^{x^2} dx \leq e.$$

86. (a) Let $f(x) = e^x - 1 - x - \frac{1}{2}x^2$. Thus, $f'(x) = e^x - 1 - x$, which is positive for $x \geq 0$ by Exercise 85(a).

Thus $f(x)$ is increasing on $(0, \infty)$, so on that interval, $0 = f(0) \leq f(x) = e^x - 1 - x - \frac{1}{2}x^2 \Rightarrow e^x \geq 1 + x + \frac{1}{2}x^2$.

(b) Using the same argument as in Exercise 85(b), from part (a) we have $1 + x^2 + \frac{1}{2}x^4 \leq e^{x^2} \leq e^x$

$$[\text{for } 0 \leq x \leq 1] \Rightarrow \int_0^1 (1 + x^2 + \frac{1}{2}x^4) dx \leq \int_0^1 e^{x^2} dx \leq \int_0^1 e^x dx \Rightarrow \frac{43}{30} \leq \int_0^1 e^{x^2} dx \leq e - 1.$$

87. (a) By Exercise 85(a), the result holds for $n = 1$. Suppose that $e^x \geq 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^k}{k!}$ for $x \geq 0$.

Let $f(x) = e^x - 1 - x - \frac{x^2}{2!} - \cdots - \frac{x^k}{k!} - \frac{x^{k+1}}{(k+1)!}$. Then $f'(x) = e^x - 1 - x - \cdots - \frac{x^k}{k!} \geq 0$

by assumption. Hence $f(x)$ is increasing on $(0, \infty)$. So $0 \leq x$ implies that

$$0 = f(0) \leq f(x) = e^x - 1 - x - \cdots - \frac{x^k}{k!} - \frac{x^{k+1}}{(k+1)!}, \text{ and hence } e^x \geq 1 + x + \cdots + \frac{x^k}{k!} + \frac{x^{k+1}}{(k+1)!}$$

for $x \geq 0$. Therefore, for $x \geq 0$, $e^x \geq 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!}$ for every positive integer n , by mathematical induction.

- (b) Taking $n = 4$ and $x = 1$ in (a), we have $e = e^1 \geq 1 + \frac{1}{2} + \frac{1}{6} + \frac{1}{24} = 2.708\bar{3} > 2.7$.

$$(c) e^x \geq 1 + x + \cdots + \frac{x^k}{k!} + \frac{x^{k+1}}{(k+1)!} \Rightarrow \frac{e^x}{x^k} \geq \frac{1}{x^k} + \frac{1}{x^{k-1}} + \cdots + \frac{1}{k!} + \frac{x}{(k+1)!} \geq \frac{x}{(k+1)!}.$$

$$\text{But } \lim_{x \rightarrow \infty} \frac{x}{(k+1)!} = \infty, \text{ so } \lim_{x \rightarrow \infty} \frac{e^x}{x^k} = \infty.$$

7.3 Logarithmic Functions

1. (a) It is defined as the inverse of the exponential function with base a , that is, $\log_a x = y \Leftrightarrow a^y = x$.
 (b) $(0, \infty)$ (c) $\mathbb{R}$ (d) See Figure 1.
2. (a) The natural logarithm is the logarithm with base e , denoted $\ln x$.
 (b) The common logarithm is the logarithm with base 10, denoted $\log x$.
 (c) See Figure 3.
3. (a) $\log_{10} 1000 = 3$ because $10^3 = 1000$. Or: $\log_{10} 1000 = \log_{10} 10^3 = 3$ by (2).
 (b) $\log_{16} 4 = \frac{1}{2}$ because $16^{1/2} = 4$. Or: $\log_{16} 4 = \log_{16} 16^{1/2} = \frac{1}{2}$ by (2).
4. (a) By (6), $\ln e^{-100} = -100$. (b) $\log_3 81 = 4$ since $3^4 = 81$.
5. (a) $\log_5 \frac{1}{25} = \log_5 5^{-2} = -2$ by (2). (b) $e^{\ln 15} = 15$ by (6).
6. (a) $\log_{10} 0.1 = -1$ since $10^{-1} = 0.1$.
 (b) $\log_8 320 - \log_8 5 = \log_8 \frac{320}{5} = \log_8 64 = 2$ since $8^2 = 64$.
7. (a) $\log_{12} 3 + \log_{12} 48 = \log_{12} (3 \cdot 48) = \log_{12} 144 = 2$ since $12^2 = 144$.
 (b) $\log_2 5 - \log_2 90 + 2 \log_2 3 = \log_2 5 + \log_2 3^2 - \log_2 90 = \log_2 (5 \cdot 9) - \log_2 90$
 $= \log_2 \left(\frac{45}{90} \right) = \log_2 \left(\frac{1}{2} \right) = -1$ since $2^{-1} = \frac{1}{2}$.
8. (a) $2^{(\log_2 3 + \log_2 5)} = 2^{\log_2 15} = 15$ [Or: $2^{(\log_2 3 + \log_2 5)} = 2^{\log_2 3} \cdot 2^{\log_2 5} = 3 \cdot 5 = 15$]
 (b) $e^{3 \ln 2} = e^{\ln(2^3)} = e^{\ln 8} = 8$ [Or: $e^{3 \ln 2} = (e^{\ln 2})^3 = 2^3 = 8$]
9. $\log_2 \left(\frac{x^3 y}{z^2} \right) = \log_2 (x^3 y) - \log_2 z^2 = \log_2 x^3 + \log_2 y - \log_2 z^2 = 3 \log_2 x + \log_2 y - 2 \log_2 z$
 (assuming that the variables are positive)
10. $\ln \sqrt{a(b^2 + c^2)} = \ln(a(b^2 + c^2))^{1/2} = \frac{1}{2} \ln(a(b^2 + c^2)) = \frac{1}{2} [\ln a + \ln(b^2 + c^2)]$
 $= \frac{1}{2} \ln a + \frac{1}{2} \ln(b^2 + c^2)$

$$11. \ln(uv)^{10} = 10 \ln(uv) = 10(\ln u + \ln v) = 10 \ln u + 10 \ln v$$

$$12. \ln \frac{3x^2}{(x+1)^5} = \ln 3x^2 - \ln(x+1)^5 = \ln 3 + \ln x^2 - 5 \ln(x+1) = \ln 3 + 2 \ln x - 5 \ln(x+1)$$

$$13. \log_{10} a - \log_{10} b + \log_{10} c = \log_{10} \frac{a}{b} + \log_{10} c = \log_{10} \left(\frac{a}{b} \cdot c \right) = \log_{10} \frac{ac}{b}$$

$$14. \ln(x+y) + \ln(x-y) - 2 \ln z = \ln((x+y)(x-y)) - \ln z^2 = \ln(x^2 - y^2) - \ln z^2 = \ln \frac{x^2 - y^2}{z^2}$$

$$15. 2 \ln 4 - \ln 2 = \ln 4^2 - \ln 2 = \ln 16 - \ln 2 = \ln \frac{16}{2} = \ln 8$$

$$16. \ln 3 + \frac{1}{3} \ln 8 = \ln 3 + \ln 8^{1/3} = \ln 3 + \ln 2 = \ln(3 \cdot 2) = \ln 6$$

$$17. \frac{1}{2} \ln x - 5 \ln(x^2 + 1) = \ln x^{1/2} - \ln(x^2 + 1)^5 = \ln \frac{\sqrt{x}}{(x^2 + 1)^5}$$

$$18. \ln x + a \ln y - b \ln z = \ln x + \ln y^a - \ln z^b = \ln(x \cdot y^a) - \ln z^b = \ln(xy^a/z^b)$$

$$19. (a) \log_{12} e = \frac{\ln e}{\ln 12} = \frac{1}{\ln 12} \approx 0.402430$$

$$(b) \log_6 13.54 = \frac{\ln 13.54}{\ln 6} \approx 1.454240$$

$$(c) \log_2 \pi = \frac{\ln \pi}{\ln 2} \approx 1.651496$$

$$20. \text{To graph the functions, we use } \log_2 x = \frac{\ln x}{\ln 2}, \log_4 x = \frac{\ln x}{\ln 4}, \text{ etc.}$$

These graphs all approach $-\infty$ as $x \rightarrow 0^+$, and they all pass through the point $(1, 0)$. Also, they are all increasing, and all approach ∞ as $x \rightarrow \infty$. The smaller the base, the larger the rate of increase of the function (for $x > 1$) and the closer the approach to the y -axis (as $x \rightarrow 0^+$).

$$21. \text{To graph these functions, we use } \log_{1.5} x = \frac{\ln x}{\ln 1.5} \text{ and}$$

$\log_{50} x = \frac{\ln x}{\ln 50}$. These graphs all approach $-\infty$ as $x \rightarrow 0^+$, and they all pass through the point $(1, 0)$. Also, they are all increasing, and all approach ∞ as $x \rightarrow \infty$. The functions with larger bases increase extremely slowly, and the ones with smaller bases do so somewhat more quickly. The functions with large bases approach the y -axis more closely as $x \rightarrow 0^+$.

22. We see that the graph of $\ln x$ is the reflection of the graph of e^x about the line $y = x$, and that the graph of $\log_{10} x$ is the reflection of the graph of 10^x about the same line. The graph of 10^x increases more quickly than that of e^x . Also note that $\log_{10} x \rightarrow \infty$ as $x \rightarrow \infty$ more slowly than $\ln x$.

23. Shift the graph of $y = \log_{10} x$ five units to the left to obtain the graph of $y = \log_{10}(x + 5)$.
Note the vertical asymptote of $x = -5$.

25. Reflect the graph of $y = \ln x$ about the x -axis to obtain the graph of $y = -\ln x$.

24. $\log_2(x - 3)$: Start with the graph of $y = \log_2 x$ and shift 3 units to the right.

26. $y = \ln(10x)$: Start with the graph of $y = \ln x$ and compress horizontally by a factor of 10.
Or: $y = \ln(10x) = \ln 10 + \ln x$, so we could start with $y = \ln x$ and shift $\ln 10$ units upward.

27. $y = 5 + \ln(x - 2)$: Start with the graph of $y = \ln x$, shift 2 units to the right and then shift 5 units upward.

28. Reflect the portion of the graph of $y = \ln x$ to the right of the y -axis about the y -axis. The graph of $y = \ln|x|$ is that reflection in addition to the original portion.

29. (a) $2 \ln x = 1 \Rightarrow \ln x = \frac{1}{2} \Rightarrow x = e^{1/2} = \sqrt{e}$
 (b) $e^{-x} = 5 \Rightarrow -x = \ln 5 \Rightarrow x = -\ln 5$
30. (a) $e^{2x+3} - 7 = 0 \Rightarrow e^{2x+3} = 7 \Rightarrow 2x+3 = \ln 7 \Rightarrow 2x = \ln 7 - 3 \Rightarrow x = \frac{1}{2}(\ln 7 - 3)$
 (b) $\ln(5-2x) = -3 \Rightarrow 5-2x = e^{-3} \Rightarrow 2x = 5 - e^{-3} \Rightarrow x = \frac{1}{2}(5 - e^{-3})$
31. (a) $5^{x-3} = 10 \Leftrightarrow \log_{10} 5^{x-3} = \log_{10} 10 \Leftrightarrow (x-3) \log_{10} 5 = 1 \Leftrightarrow x-3 = 1/\log_{10} 5 \Leftrightarrow x = 3 + 1/\log_{10} 5$
 (b) $\log_{10}(x+1) = 4 \Leftrightarrow x+1 = 10^4 \Leftrightarrow x = 10,000 - 1 = 9999$
32. (a) $e^{3x+1} = k \Leftrightarrow 3x+1 = \ln k \Leftrightarrow x = \frac{1}{3}(\ln k - 1)$
 (b) $\log_2(mx) = c \Leftrightarrow mx = 2^c \Leftrightarrow x = 2^c/m$
33. $\ln(\ln x) = 1 \Leftrightarrow e^{\ln(\ln x)} = e^1 \Leftrightarrow \ln x = e^1 = e \Leftrightarrow e^{\ln x} = e^e \Leftrightarrow x = e^e$
34. $e^{e^x} = 10 \Leftrightarrow \ln(e^{e^x}) = \ln 10 \Leftrightarrow e^x \ln e = e^x = \ln 10 \Leftrightarrow \ln e^x = \ln(\ln 10) \Leftrightarrow x = \ln(\ln 10)$
35. $2 \ln x = \ln 2 + \ln(3x-4) \Rightarrow \ln x^2 = \ln[2(3x-4)] \Rightarrow \ln x^2 = \ln(6x-8) \Rightarrow x^2 = 6x-8 \Rightarrow x^2 - 6x + 8 = 0 \Rightarrow (x-2)(x-4) = 0 \Rightarrow x = 2 \text{ or } x = 4, \text{ both are valid solutions.}$
36. $\ln(2x+1) = 2 - \ln x \Rightarrow \ln x + \ln(2x+1) = \ln e^2 \Rightarrow \ln[x(2x+1)] = \ln e^2 \Rightarrow 2x^2 + x = e^2 \Rightarrow 2x^2 + x - e^2 = 0 \Rightarrow x = \frac{-1 + \sqrt{1+8e^2}}{4} \text{ [since } x > 0\text{].}$
37. $e^{ax} = Ce^{bx} \Leftrightarrow \ln e^{ax} = \ln[C(e^{bx})] \Leftrightarrow ax = \ln C + bx + \ln e^{bx} \Leftrightarrow ax = \ln C + bx \Leftrightarrow ax - bx = \ln C \Leftrightarrow (a-b)x = \ln C \Leftrightarrow x = \frac{\ln C}{a-b}$
38. $7e^x - e^{2x} = 12 \Leftrightarrow (e^x)^2 - 7e^x + 12 = 0 \Leftrightarrow (e^x - 3)(e^x - 4) = 0$, so we have either $e^x = 3 \Leftrightarrow x = \ln 3$, or $e^x = 4 \Leftrightarrow x = \ln 4$.
39. $e^{2+5x} = 100 \Rightarrow \ln(e^{2+5x}) = \ln 100 \Rightarrow 2+5x = \ln 100 \Rightarrow 5x = \ln 100 - 2 \Rightarrow x = \frac{1}{5}(\ln 100 - 2) \approx 0.5210$
40. $\ln(1+\sqrt{x}) = 2 \Rightarrow 1+\sqrt{x} = e^2 \Rightarrow \sqrt{x} = e^2 - 1 \Rightarrow x = (e^2 - 1)^2 \approx 40.8200$
41. $\ln(e^x - 2) = 3 \Rightarrow e^x - 2 = e^3 \Rightarrow e^x = e^3 + 2 \Rightarrow x = \ln(e^3 + 2) \approx 3.0949$
42. $3^{1/(x-4)} = 7 \Rightarrow \ln 3^{1/(x-4)} = \ln 7 \Rightarrow \frac{1}{x-4} \ln 3 = \ln 7 \Rightarrow x-4 = \frac{\ln 3}{\ln 7} \Rightarrow x = 4 + \frac{\ln 3}{\ln 7} \approx 4.5646$
43. (a) $e^x < 10 \Rightarrow \ln e^x < \ln 10 \Rightarrow x < \ln 10 \Rightarrow x \in (-\infty, \ln 10)$
 (b) $\ln x > -1 \Rightarrow e^{\ln x} > e^{-1} \Rightarrow x > e^{-1} \Rightarrow x \in (1/e, \infty)$
44. (a) $2 < \ln x < 9 \Rightarrow e^2 < e^{\ln x} < e^9 \Rightarrow e^2 < x < e^9 \Rightarrow x \in (e^2, e^9)$
 (b) $e^{2-3x} > 4 \Rightarrow \ln e^{2-3x} > \ln 4 \Rightarrow 2-3x > \ln 4 \Rightarrow -3x > \ln 4 - 2 \Rightarrow x < -\frac{1}{3}(\ln 4 - 2) \Rightarrow x \in (-\infty, \frac{1}{3}(2 - \ln 4))$
45. 3 ft = 36 in, so we need x such that $\log_2 x = 36 \Leftrightarrow x = 2^{36} = 68,719,476,736$. In miles, this is $68,719,476,736 \text{ in} \cdot \frac{1 \text{ ft}}{12 \text{ in}} \cdot \frac{1 \text{ mi}}{5280 \text{ ft}} \approx 1,084,587.7 \text{ mi}.$

46. (a) $v(t) = ce^{-kt} \Rightarrow a(t) = v'(t) = -kce^{-kt} = -kv(t)$

(b) $v(0) = ce^0 = c$, so c is the initial velocity.

(c) $v(t) = ce^{-kt} = c/2 \Rightarrow e^{-kt} = \frac{1}{2} \Rightarrow -kt = \ln \frac{1}{2} = -\ln 2 \Rightarrow t = (\ln 2)/k$

47. If I is the intensity of the 1989 San Francisco earthquake, then $\log_{10}(I/S) = 7.1 \Rightarrow$

$\log_{10}(16I/S) = \log_{10} 16 + \log_{10}(I/S) = \log_{10} 16 + 7.1 \approx 8.3.$

48. Let I_1 and I_2 be the intensities of the music and the mower. Then $10 \log_{10}\left(\frac{I_1}{I_0}\right) = 120$ and $10 \log_{10}\left(\frac{I_2}{I_0}\right) = 106$,

so $\log_{10}\left(\frac{I_1}{I_2}\right) = \log_{10}\left(\frac{I_1/I_0}{I_2/I_0}\right) = \log_{10}\left(\frac{I_1}{I_0}\right) - \log_{10}\left(\frac{I_2}{I_0}\right) = 12 - 10.6 = 1.4 \Rightarrow \frac{I_1}{I_2} = 10^{1.4} \approx 25.$

49. (a) $n = 100 \cdot 2^{t/3} \Rightarrow \frac{n}{100} = 2^{t/3} \Rightarrow \log_2\left(\frac{n}{100}\right) = \frac{t}{3} \Rightarrow t = 3 \log_2\left(\frac{n}{100}\right)$. Using formula (7), we can write this as $t = 3 \cdot \frac{\ln(n/100)}{\ln 2}$. This function tells us how long it will take to obtain n bacteria (given the number n).

(b) $n = 50,000 \Rightarrow t = 3 \log_2 \frac{50,000}{100} = 3 \log_2 500 = 3 \left(\frac{\ln 500}{\ln 2} \right) \approx 26.9$ hours

50. (a) $Q = Q_0(1 - e^{-t/a}) \Rightarrow \frac{Q}{Q_0} = 1 - e^{-t/a} \Rightarrow e^{-t/a} = 1 - \frac{Q}{Q_0} \Rightarrow -\frac{t}{a} = \ln\left(1 - \frac{Q}{Q_0}\right) \Rightarrow$
 $t = -a \ln(1 - Q/Q_0)$. This gives us the time t necessary to obtain a given charge Q .

(b) $Q = 0.9Q_0$ and $a = 2 \Rightarrow t = -2 \ln(1 - 0.9(Q_0/Q_0)) = -2 \ln 0.1 \approx 4.6$ seconds.

51. Let $t = 2 - x$. As $x \rightarrow 2^-$, $t \rightarrow 0^+$. $\lim_{x \rightarrow 2^-} \ln(2 - x) = \lim_{t \rightarrow 0^+} \ln t = -\infty$ by (8).

52. Let $t = x^2 - 5x + 6$. As $x \rightarrow 3^+$, $t = (x - 2)(x - 3) \rightarrow 0^+$. $\lim_{x \rightarrow 3^+} \log_{10}(x^2 - 5x + 6) = \lim_{t \rightarrow 0^+} \log_{10} t = -\infty$ by (4).

53. $\lim_{x \rightarrow 0} \ln(\cos x) = \ln 1 = 0$. [$\ln(\cos x)$ is continuous at $x = 0$ since it is the composite of two continuous functions.]

54. $\lim_{x \rightarrow 0^+} \ln(\sin x) = -\infty$ since $\sin x \rightarrow 0^+$ as $x \rightarrow 0^+$.

55. $\lim_{x \rightarrow \infty} [\ln(1 + x^2) - \ln(1 + x)] = \lim_{x \rightarrow \infty} \ln \frac{1 + x^2}{1 + x} = \ln \left(\lim_{x \rightarrow \infty} \frac{1 + x^2}{1 + x} \right) = \ln \left(\lim_{x \rightarrow \infty} \frac{\frac{1}{x} + x}{\frac{1}{x} + 1} \right) = \infty$, since the limit in parentheses is ∞ .

56. $\lim_{x \rightarrow \infty} [\ln(2 + x) - \ln(1 + x)] = \lim_{x \rightarrow \infty} \ln \left(\frac{2 + x}{1 + x} \right) = \lim_{x \rightarrow \infty} \ln \left(\frac{2/x + 1}{1/x + 1} \right) = \ln \frac{1}{1} = \ln 1 = 0$

57. The domain of $f(x) = \log_2(5x - 3)$ is $\{x \mid 5x - 3 > 0\} = \{x \mid x > \frac{3}{5}\} = (\frac{3}{5}, \infty)$. Since $5x - 3$ takes on all positive values for x in $(\frac{3}{5}, \infty)$, the range of f is $\mathbb{R}$.

58. The domain of $G(t) = \ln(e^t - 2)$ is $\{t \mid e^t - 2 > 0\} = \{t \mid e^t > 2\} = \{t \mid t > \ln 2\} = (\ln 2, \infty)$. Since $e^t - 2$ takes on all positive values for t in $(\ln 2, \infty)$, the range of G is $\mathbb{R}$.

59. (a) For $f(x) = \sqrt{3 - e^{2x}}$, we must have $3 - e^{2x} \geq 0 \Rightarrow e^{2x} \leq 3 \Rightarrow 2x \leq \ln 3 \Rightarrow x \leq \frac{1}{2} \ln 3$.
 Thus, the domain of f is $(-\infty, \frac{1}{2} \ln 3]$.

(b) $y = f(x) = \sqrt{3 - e^{2x}}$ [note that $y \geq 0$] $\Rightarrow y^2 = 3 - e^{2x} \Rightarrow e^{2x} = 3 - y^2 \Rightarrow 2x = \ln(3 - y^2)$
 $\Rightarrow x = \frac{1}{2} \ln(3 - y^2)$. Interchange x and y : $y = \frac{1}{2} \ln(3 - x^2)$. So $f^{-1}(x) = \frac{1}{2} \ln(3 - x^2)$. For the domain of f^{-1} , we must have $3 - x^2 > 0 \Rightarrow x^2 < 3 \Rightarrow |x| < \sqrt{3} \Rightarrow -\sqrt{3} < x < \sqrt{3} \Rightarrow 0 \leq x < \sqrt{3}$ since $x \geq 0$. Note that the domain of f^{-1} , $[0, \sqrt{3})$, equals the range of f .

60. (a) For $f(x) = \ln(2 + \ln x)$, we must have $2 + \ln x > 0 \Rightarrow \ln x > -2 \Rightarrow x > e^{-2}$. Thus, the domain of f is (e^{-2}, ∞) .

(b) $y = f(x) = \ln(2 + \ln x) \Rightarrow e^y = 2 + \ln x \Rightarrow \ln x = e^y - 2 \Rightarrow x = e^{e^y - 2}$. Interchange x and y : $y = e^{e^x - 2}$. So $f^{-1}(x) = e^{e^x - 2}$. The domain of f^{-1} , as well as the range of f , is $\mathbb{R}$.

61. $y = \ln(x + 3) \Rightarrow e^y = e^{\ln(x+3)} = x + 3 \Rightarrow x = e^y - 3$.

Interchange x and y : the inverse function is $y = e^x - 3$.

62. $y = 2^{10^x} \Rightarrow \log_2 y = 10^x \Rightarrow \log_{10}(\log_2 y) = x$.

Interchange x and y : $y = \log_{10}(\log_2 x)$ is the inverse function.

63. $f(x) = e^{x^3} \Rightarrow y = e^{x^3} \Rightarrow \ln y = x^3 \Rightarrow x = \sqrt[3]{\ln y}$. Interchange x and y : $y = \sqrt[3]{\ln x}$.

So $f^{-1}(x) = \sqrt[3]{\ln x}$.

64. $y = (\ln x)^2, x \geq 1, \ln x = \sqrt{y} \Rightarrow x = e^{\sqrt{y}}$. Interchange x and y : $y = e^{\sqrt{x}}$ is the inverse function.

65. $y = \frac{10^x}{10^x + 1} \Rightarrow 10^x y + y = 10^x \Rightarrow 10^x(1 - y) = y \Rightarrow 10^x = \frac{y}{1 - y} \Rightarrow x = \log_{10} \left(\frac{y}{1 - y} \right)$.

Interchange x and y : $y = \log_{10} \left(\frac{x}{1 - x} \right)$ is the inverse function.

66. $y = \frac{1 + e^x}{1 - e^x} \Rightarrow y - ye^x = 1 + e^x \Rightarrow e^x(y + 1) = y - 1 \Rightarrow e^x = \frac{y - 1}{y + 1} \Rightarrow x = \ln \left(\frac{y - 1}{y + 1} \right)$.

Interchange x and y : $y = \ln \left(\frac{x - 1}{x + 1} \right)$ is the inverse function.

67. $f(x) = e^{3x} - e^x \Rightarrow f'(x) = 3e^{3x} - e^x$. Thus, $f'(x) > 0 \Leftrightarrow 3e^{3x} > e^x \Leftrightarrow \frac{3e^{3x}}{e^x} > \frac{e^x}{e^x} \Leftrightarrow 3e^{2x} > 1 \Leftrightarrow e^{2x} > \frac{1}{3} \Leftrightarrow 2x > \ln \left(\frac{1}{3} \right) = -\ln 3 \Leftrightarrow x > -\frac{1}{2} \ln 3$, so f is increasing on $(-\frac{1}{2} \ln 3, \infty)$.

68. $y = 2e^x - e^{-3x} \Rightarrow y' = 2e^x + 3e^{-3x} \Rightarrow y'' = 2e^x - 9e^{-3x}$. Thus, $y'' < 0 \Leftrightarrow 2e^x < 9e^{-3x} \Leftrightarrow e^{4x} < \frac{9}{2} \Leftrightarrow 4x < \ln \frac{9}{2} \Leftrightarrow x < \frac{1}{4} \ln \frac{9}{2}$, so f is concave downward on $(-\infty, \frac{1}{4} \ln \frac{9}{2})$.

69. (a) We have to show that $-f(x) = f(-x)$.

$$\begin{aligned} -f(x) &= -\ln(x + \sqrt{x^2 + 1}) = \ln \left((x + \sqrt{x^2 + 1})^{-1} \right) = \ln \frac{1}{x + \sqrt{x^2 + 1}} \\ &= \ln \left(\frac{1}{x + \sqrt{x^2 + 1}} \cdot \frac{x - \sqrt{x^2 + 1}}{x - \sqrt{x^2 + 1}} \right) = \ln \frac{x - \sqrt{x^2 + 1}}{x^2 - x^2 - 1} \\ &= \ln(\sqrt{x^2 + 1} - x) = f(-x) \end{aligned}$$

Thus, f is an odd function.

(b) Let $y = \ln(x + \sqrt{x^2 + 1})$. Then $e^y = x + \sqrt{x^2 + 1} \Leftrightarrow (e^y - x)^2 = x^2 + 1 \Leftrightarrow$

$$e^{2y} - 2xe^y + x^2 = x^2 + 1 \Leftrightarrow 2xe^y = e^{2y} - 1 \Leftrightarrow x = \frac{e^{2y} - 1}{2e^y} = \frac{1}{2}(e^y - e^{-y}). \text{ Thus, the inverse}$$

function is $f^{-1}(x) = \frac{1}{2}(e^x - e^{-x})$.

70. Let (a, e^{-a}) be the point where the tangent meets the curve. The tangent has slope $-e^{-a}$ and is perpendicular to the line $2x - y = 8$, which has slope 2. So $-e^{-a} = -\frac{1}{2} \Rightarrow e^{-a} = \frac{1}{2} \Rightarrow e^a = 2 \Rightarrow a = \ln(e^a) = \ln 2$. Thus, the point on the curve is $(\ln 2, \frac{1}{2})$ and the equation of the tangent is $y - \frac{1}{2} = -\frac{1}{2}(x - \ln 2)$ or $x + 2y = 1 + \ln 2$.

71. $x^{1/\ln x} = 2 \Rightarrow \ln(x^{1/\ln x}) = \ln(2) \Rightarrow \frac{1}{\ln x} \cdot \ln x = \ln 2 \Rightarrow 1 = \ln 2$, a contradiction, so the given equation has no solution. The function $f(x) = x^{1/\ln x} = (e^{\ln x})^{1/\ln x} = e^1 = e$ for all $x > 0$, so the function $f(x) = x^{1/\ln x}$ is the constant function $f(x) = e$.

72. (a) $\lim_{x \rightarrow \infty} x^{\ln x} = \lim_{x \rightarrow \infty} (e^{\ln x})^{\ln x} = \lim_{x \rightarrow \infty} e^{(\ln x)^2} = \infty$ since $(\ln x)^2 \rightarrow \infty$ as $x \rightarrow \infty$.

(b) $\lim_{x \rightarrow 0^+} x^{-\ln x} = \lim_{x \rightarrow 0^+} (e^{\ln x})^{-\ln x} = \lim_{x \rightarrow 0^+} e^{-(\ln x)^2} = 0$ since $-(\ln x)^2 \rightarrow -\infty$ as $x \rightarrow 0^+$.

(c) $\lim_{x \rightarrow 0^+} x^{1/x} = \lim_{x \rightarrow 0^+} (e^{\ln x})^{1/x} = \lim_{x \rightarrow 0^+} e^{(\ln x)/x} = 0$ since $\frac{\ln x}{x} \rightarrow -\infty$ as $x \rightarrow 0^+$. Note that as $x \rightarrow 0^+$, $\ln x$ is a large negative number and x is a small positive number, so $(\ln x)/x \rightarrow -\infty$.

(d) $\lim_{x \rightarrow \infty} (\ln 2x)^{-\ln x} = \lim_{x \rightarrow \infty} [e^{\ln(\ln 2x)}]^{-\ln x} = \lim_{x \rightarrow \infty} e^{-\ln x \ln(\ln 2x)} = 0$ since $-\ln x \ln(\ln 2x) \rightarrow -\infty$ as $x \rightarrow \infty$.

73. (a) Let $\varepsilon > 0$ be given. We need N such that $|a^x - 0| < \varepsilon$ when $x < N$. But $a^x < \varepsilon \Leftrightarrow x < \log_a \varepsilon$. Let $N = \log_a \varepsilon$. Then $x < N \Rightarrow x < \log_a \varepsilon \Rightarrow |a^x - 0| = a^x < \varepsilon$, so $\lim_{x \rightarrow -\infty} a^x = 0$.

(b) Let $M > 0$ be given. We need N such that $a^x > M$ when $x > N$. But $a^x > M \Leftrightarrow x > \log_a M$. Let $N = \log_a M$. Then $x > N \Rightarrow x > \log_a M \Rightarrow a^x > M$, so $\lim_{x \rightarrow \infty} a^x = \infty$.

From the graphs, we see that $f(x) = x^{0.1} > g(x) = \ln x$ for approximately $0 < x < 3.06$, and then $g(x) > f(x)$ for $3.06 < x < 3.43 \times 10^{15}$ (approximately). At that point, the graph of f finally surpasses the graph of g for good.

(c) From the graph at left, it seems that $\frac{\ln x}{x^{0.1}} < 0.1$ whenever $x > 1.3 \times 10^{28}$ (approximately). So we can take $N = 1.3 \times 10^{28}$, or any larger number.

75. $\ln(x^2 - 2x - 2) \leq 0 \Rightarrow 0 < x^2 - 2x - 2 \leq 1$. Now $x^2 - 2x - 2 \leq 1$ gives $x^2 - 2x - 3 \leq 0$ and hence $(x - 3)(x + 1) \leq 0$. So $-1 \leq x \leq 3$. Now $0 < x^2 - 2x - 2 \Rightarrow x < 1 - \sqrt{3}$ or $x > 1 + \sqrt{3}$. Therefore, $\ln(x^2 - 2x - 2) \leq 0 \Leftrightarrow -1 \leq x < 1 - \sqrt{3}$ or $1 + \sqrt{3} < x \leq 3$.

76. (a) The primes less than 25 are 2, 3, 5, 7, 11, 13, 17, 19, and 23. There are 9 of them, so $\pi(25) = 9$. We use the sieve of Eratosthenes, and arrive at the figure at right. There are 25 numbers left over, so $\pi(100) = 25$.

	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20
21	22	23	24	25	26	27	28	29	30
31	32	33	34	35	36	37	38	39	40
41	42	43	44	45	46	47	48	49	50
51	52	53	54	55	56	57	58	59	60
61	62	63	64	65	66	67	68	69	70
71	72	73	74	75	76	77	78	79	80
81	82	83	84	85	86	87	88	89	90
91	92	93	94	95	96	97	98	99	100

- (b) Let $f(n) = \frac{\pi(n)}{n/\ln n}$. We compute $f(100) = \frac{25}{100/\ln 100} \approx 1.15$,
 $f(1000) \approx 1.16$, $f(10^4) \approx 1.13$, $f(10^5) \approx 1.10$, $f(10^6) \approx 1.08$,
 and $f(10^7) \approx 1.07$.
- (c) By the Prime Number Theorem, the number of primes less than a billion, that is, $\pi(10^9)$, should be close to $10^9/\ln 10^9 \approx 48,254,942$. In fact, $\pi(10^9) = 50,847,543$, so our estimate is off by about 5.1%. Do not attempt this calculation at home.

7.4 Derivatives of Logarithmic Functions

- The differentiation formula for logarithmic functions, $\frac{d}{dx}(\log_a x) = \frac{1}{x \ln a}$, is simplest when $a = e$ because $\ln e = 1$.
- $f(x) = \ln(x^2 + 10) \Rightarrow f'(x) = \frac{1}{x^2 + 10} \cdot \frac{d}{dx}(x^2 + 10) = \frac{2x}{x^2 + 10}$
- $f(\theta) = \ln(\cos \theta) \Rightarrow f'(\theta) = \frac{1}{\cos \theta} \cdot \frac{d}{d\theta}(\cos \theta) = \frac{-\sin \theta}{\cos \theta} = -\tan \theta$
- $f(x) = \cos(\ln x) \Rightarrow f'(x) = -\sin(\ln x) \cdot \frac{1}{x} = \frac{-\sin(\ln x)}{x}$
- $f(x) = \log_2(1 - 3x) \Rightarrow f'(x) = \frac{1}{(1 - 3x) \ln 2} \cdot \frac{d}{dx}(1 - 3x) = \frac{-3}{(1 - 3x) \ln 2}$ or $\frac{3}{(3x - 1) \ln 2}$
- $f(x) = \log_{10}\left(\frac{x}{x - 1}\right) = \log_{10} x - \log_{10}(x - 1) \Rightarrow f'(x) = \frac{1}{x \ln 10} - \frac{1}{(x - 1) \ln 10}$ or $-\frac{1}{x(x - 1) \ln 10}$
- $f(x) = \sqrt[5]{\ln x} = (\ln x)^{1/5} \Rightarrow f'(x) = \frac{1}{5}(\ln x)^{-4/5} \cdot \frac{d}{dx}(\ln x) = \frac{1}{5(\ln x)^{4/5}} \cdot \frac{1}{x} = \frac{1}{5x \sqrt[5]{(\ln x)^4}}$
- $f(x) = \ln \sqrt[5]{x} = \ln x^{1/5} = \frac{1}{5} \ln x \Rightarrow f'(x) = \frac{1}{5} \cdot \frac{1}{x} = \frac{1}{5x}$
- $f(x) = \sqrt{x} \ln x \Rightarrow f'(x) = \sqrt{x} \left(\frac{1}{x}\right) + (\ln x) \cdot \frac{1}{2\sqrt{x}} = \frac{1}{\sqrt{x}} + \frac{\ln x}{2\sqrt{x}} = \frac{2 + \ln x}{2\sqrt{x}}$
- $f(t) = \frac{1 + \ln t}{1 - \ln t} \Rightarrow$
 $f'(t) = \frac{(1 - \ln t)(1/t) - (1 + \ln t)(-1/t)}{(1 - \ln t)^2} = \frac{(1/t)[(1 - \ln t) + (1 + \ln t)]}{(1 - \ln t)^2} = \frac{2}{t(1 - \ln t)^2}$
- $F(t) = \ln \frac{(2t + 1)^3}{(3t - 1)^4} = \ln(2t + 1)^3 - \ln(3t - 1)^4 = 3 \ln(2t + 1) - 4 \ln(3t - 1) \Rightarrow$
 $F'(t) = 3 \cdot \frac{1}{2t + 1} \cdot 2 - 4 \cdot \frac{1}{3t - 1} \cdot 3 = \frac{6}{2t + 1} - \frac{12}{3t - 1}$, or combined, $\frac{-6(t + 3)}{(2t + 1)(3t - 1)}$.

$$12. h(x) = \ln(x + \sqrt{x^2 - 1}) \Rightarrow$$

$$h'(x) = \frac{1}{x + \sqrt{x^2 - 1}} \left(1 + \frac{x}{\sqrt{x^2 - 1}} \right) = \frac{1}{x + \sqrt{x^2 - 1}} \cdot \frac{\sqrt{x^2 - 1} + x}{\sqrt{x^2 - 1}} = \frac{1}{\sqrt{x^2 - 1}}$$

$$13. g(x) = \ln \frac{a-x}{a+x} = \ln(a-x) - \ln(a+x) \Rightarrow$$

$$g'(x) = \frac{1}{a-x}(-1) - \frac{1}{a+x} = \frac{-(a+x) - (a-x)}{(a-x)(a+x)} = \frac{-2a}{a^2 - x^2}$$

$$14. F(y) = y \ln(1 + e^y) \Rightarrow F'(y) = y \cdot \frac{1}{1 + e^y} \cdot e^y + \ln(1 + e^y) \cdot 1 = \frac{ye^y}{1 + e^y} + \ln(1 + e^y)$$

$$15. f(u) = \frac{\ln u}{1 + \ln(2u)} \Rightarrow$$

$$\begin{aligned} f'(u) &= \frac{[1 + \ln(2u)] \cdot \frac{1}{u} - \ln u \cdot \frac{1}{2u} \cdot 2}{[1 + \ln(2u)]^2} = \frac{\frac{1}{u} [1 + \ln(2u) - \ln u]}{[1 + \ln(2u)]^2} \\ &= \frac{1 + (\ln 2 + \ln u) - \ln u}{u [1 + \ln(2u)]^2} = \frac{1 + \ln 2}{u [1 + \ln(2u)]^2} \end{aligned}$$

$$16. y = \ln(x^4 \sin^2 x) = \ln x^4 + \ln(\sin x)^2 = 4 \ln x + 2 \ln \sin x \Rightarrow y' = 4 \cdot \frac{1}{x} + 2 \cdot \frac{1}{\sin x} \cdot \cos x = \frac{4}{x} + 2 \cot x$$

$$17. h(t) = t^3 - 3^t \Rightarrow h'(t) = 3t^2 - 3^t \ln 3$$

$$18. y = 10^{\tan \theta} \Rightarrow y' = 10^{\tan \theta} (\ln 10)(\sec^2 \theta)$$

$$19. y = \ln |2 - x - 5x^2| \Rightarrow y' = \frac{1}{2 - x - 5x^2} \cdot (-1 - 10x) = \frac{-10x - 1}{2 - x - 5x^2} \text{ or } \frac{10x + 1}{5x^2 + x - 2}$$

$$20. G(u) = \ln \sqrt{\frac{3u+2}{3u-2}} = \frac{1}{2} [\ln(3u+2) - \ln(3u-2)] \Rightarrow G'(u) = \frac{1}{2} \left(\frac{3}{3u+2} - \frac{3}{3u-2} \right) = \frac{-6}{9u^2 - 4}$$

$$21. y = \ln(e^{-x} + xe^{-x}) = \ln(e^{-x}(1+x)) = \ln(e^{-x}) + \ln(1+x) = -x + \ln(1+x) \Rightarrow$$

$$y' = -1 + \frac{1}{1+x} = \frac{-1-x+1}{1+x} = -\frac{x}{1+x}$$

$$22. y = [\ln(1 + e^x)]^2 \Rightarrow y' = 2[\ln(1 + e^x)] \cdot \frac{1}{1 + e^x} \cdot e^x = \frac{2e^x \ln(1 + e^x)}{1 + e^x}$$

$$23. \text{Using Formula 7 and the Chain Rule, } y = 5^{-1/x} \Rightarrow y' = 5^{-1/x} (\ln 5) [-1 \cdot (-x^{-2})] = 5^{-1/x} (\ln 5) / x^2$$

$$24. y = 2^{3x^2} \Rightarrow y' = 2^{3x^2} (\ln 2) \frac{d}{dx} (3x^2) = 2^{3x^2} (\ln 2) 3x^2 (\ln 3) (2x)$$

$$25. y = x \ln x \Rightarrow y' = x(1/x) + (\ln x) \cdot 1 = 1 + \ln x \Rightarrow y'' = 1/x$$

$$26. y = \frac{\ln x}{x^2} \Rightarrow y' = \frac{x^2(1/x) - (\ln x)(2x)}{(x^2)^2} = \frac{x(1 - 2 \ln x)}{x^4} = \frac{1 - 2 \ln x}{x^3} \Rightarrow$$

$$y'' = \frac{x^3(-2/x) - (1 - 2 \ln x)(3x^2)}{(x^3)^2} = \frac{x^2(-2 - 3 + 6 \ln x)}{x^6} = \frac{6 \ln x - 5}{x^4}$$

$$27. y = \log_{10} x \Rightarrow y' = \frac{1}{x \ln 10} = \frac{1}{\ln 10} \left(\frac{1}{x} \right) \Rightarrow y'' = \frac{1}{\ln 10} \left(-\frac{1}{x^2} \right) = -\frac{1}{x^2 \ln 10}$$

$$28. y = \ln(\sec x + \tan x) \Rightarrow y' = \frac{\sec x \tan x + \sec^2 x}{\sec x + \tan x} = \sec x \Rightarrow y'' = \sec x \tan x$$

$$29. f(x) = \frac{x}{1 - \ln(x-1)} \Rightarrow$$

$$\begin{aligned} f'(x) &= \frac{[1 - \ln(x-1)] \cdot 1 - x \cdot \frac{-1}{x-1}}{[1 - \ln(x-1)]^2} = \frac{(x-1)[1 - \ln(x-1)] + x}{[1 - \ln(x-1)]^2} = \frac{x-1 - (x-1)\ln(x-1) + x}{(x-1)[1 - \ln(x-1)]^2} \\ &= \frac{2x-1 - (x-1)\ln(x-1)}{(x-1)[1 - \ln(x-1)]^2} \end{aligned}$$

$$\begin{aligned} \text{Dom}(f) &= \{x \mid x-1 > 0 \text{ and } 1 - \ln(x-1) \neq 0\} = \{x \mid x > 1 \text{ and } \ln(x-1) \neq 1\} \\ &= \{x \mid x > 1 \text{ and } x-1 \neq e^1\} = \{x \mid x > 1 \text{ and } x \neq 1+e\} = (1, 1+e) \cup (1+e, \infty) \end{aligned}$$

$$30. f(x) = \frac{1}{1 + \ln x} \Rightarrow f'(x) = -\frac{1/x}{(1 + \ln x)^2} \quad [\text{Reciprocal Rule}] = -\frac{1}{x(1 + \ln x)^2}.$$

$$\text{Dom}(f) = \{x \mid x > 0 \text{ and } \ln x \neq -1\} = \{x \mid x > 0 \text{ and } x \neq 1/e\} = (0, 1/e) \cup (1/e, \infty).$$

$$31. f(x) = x^2 \ln(1-x^2) \Rightarrow f'(x) = 2x \ln(1-x^2) + \frac{x^2(-2x)}{1-x^2} = 2x \ln(1-x^2) - \frac{2x^3}{1-x^2}.$$

$$\text{Dom}(f) = \{x \mid 1-x^2 > 0\} = \{x \mid |x| < 1\} = (-1, 1).$$

$$32. f(x) = \ln \ln \ln x \Rightarrow f'(x) = \frac{1}{\ln \ln x} \cdot \frac{1}{\ln x} \cdot \frac{1}{x}.$$

$$\text{Dom}(f) = \{x \mid \ln \ln x > 0\} = \{x \mid \ln x > 1\} = \{x \mid x > e\} = (e, \infty).$$

$$33. f(x) = \frac{x}{\ln x} \Rightarrow f'(x) = \frac{\ln x - x(1/x)}{(\ln x)^2} = \frac{\ln x - 1}{(\ln x)^2} \Rightarrow f'(e) = \frac{1-1}{1^2} = 0$$

$$34. f(x) = x^2 \ln x \Rightarrow f'(x) = 2x \ln x + x^2 \left(\frac{1}{x} \right) = 2x \ln x + x \Rightarrow f'(1) = 2 \ln 1 + 1 = 1$$

$$35. y = f(x) = \ln \ln x \Rightarrow f'(x) = \frac{1}{\ln x} \left(\frac{1}{x} \right) \Rightarrow f'(e) = \frac{1}{e}, \text{ so an equation of the tangent line at } (e, 0) \text{ is}$$

$$y - 0 = \frac{1}{e}(x - e), \text{ or } y = \frac{1}{e}x - 1, \text{ or } x - ey = e.$$

$$36. y = \ln(x^3 - 7) \Rightarrow y' = \frac{1}{x^3 - 7} \cdot 3x^2 \Rightarrow y'(2) = \frac{12}{8-7} = 12, \text{ so an equation of a tangent line at } (2, 0) \text{ is}$$

$$y - 0 = 12(x - 2) \text{ or } y = 12x - 24.$$

$$37. f(x) = \sin x + \ln x \Rightarrow f'(x) = \cos x + 1/x. \text{ This is reasonable,}$$

because the graph shows that f increases when f' is positive, and

$f'(x) = 0$ when f has a horizontal tangent.

$$38. f(x) = x^{\cos x} = e^{\ln x \cos x} \Rightarrow$$

$$\begin{aligned} f'(x) &= e^{\ln x \cos x} \left[\ln x (-\sin x) + \cos x \left(\frac{1}{x} \right) \right] \\ &= x^{\cos x} \left[\frac{\cos x}{x} - \sin x \ln x \right] \end{aligned}$$

This is reasonable, because the graph shows that f increases when $f'(x)$ is positive.

$$39. y = (2x + 1)^5 (x^4 - 3)^6 \Rightarrow \ln y = \ln((2x + 1)^5 (x^4 - 3)^6) \Rightarrow$$

$$\ln y = 5 \ln(2x + 1) + 6 \ln(x^4 - 3) \Rightarrow \frac{1}{y} y' = 5 \cdot \frac{1}{2x + 1} \cdot 2 + 6 \cdot \frac{1}{x^4 - 3} \cdot 4x^3 \Rightarrow$$

$$y' = y \left(\frac{10}{2x + 1} + \frac{24x^3}{x^4 - 3} \right) = (2x + 1)^5 (x^4 - 3)^6 \left(\frac{10}{2x + 1} + \frac{24x^3}{x^4 - 3} \right).$$

[The answer could be simplified to $y' = 2(2x + 1)^4 (x^4 - 3)^5 (29x^4 + 12x^3 - 15)$, but this is unnecessary.]

$$40. y = \sqrt{x} e^{x^2} (x^2 + 1)^{10} \Rightarrow \ln y = \ln \sqrt{x} + \ln e^{x^2} + \ln(x^2 + 1)^{10} \Rightarrow \ln y = \frac{1}{2} \ln x + x^2 + 10 \ln(x^2 + 1)$$

$$\Rightarrow \frac{1}{y} y' = \frac{1}{2} \cdot \frac{1}{x} + 2x + 10 \cdot \frac{1}{x^2 + 1} \cdot 2x \Rightarrow y' = \sqrt{x} e^{x^2} (x^2 + 1)^{10} \left(\frac{1}{2x} + 2x + \frac{20x}{x^2 + 1} \right)$$

$$41. y = \frac{\sin^2 x \tan^4 x}{(x^2 + 1)^2} \Rightarrow \ln y = \ln(\sin^2 x \tan^4 x) - \ln(x^2 + 1)^2 \Rightarrow$$

$$\ln y = \ln(\sin x)^2 + \ln(\tan x)^4 - \ln(x^2 + 1)^2 \Rightarrow \ln y = 2 \ln |\sin x| + 4 \ln |\tan x| - 2 \ln(x^2 + 1) \Rightarrow$$

$$\frac{1}{y} y' = 2 \cdot \frac{1}{\sin x} \cdot \cos x + 4 \cdot \frac{1}{\tan x} \cdot \sec^2 x - 2 \cdot \frac{1}{x^2 + 1} \cdot 2x \Rightarrow$$

$$y' = \frac{\sin^2 x \tan^4 x}{(x^2 + 1)^2} \left(2 \cot x + \frac{4 \sec^2 x}{\tan x} - \frac{4x}{x^2 + 1} \right)$$

$$42. y = \sqrt[4]{\frac{x^2 + 1}{x^2 - 1}} \Rightarrow \ln y = \frac{1}{4} \ln(x^2 + 1) - \frac{1}{4} \ln(x^2 - 1) \Rightarrow \frac{1}{y} y' = \frac{1}{4} \cdot \frac{1}{x^2 + 1} \cdot 2x - \frac{1}{4} \cdot \frac{1}{x^2 - 1} \cdot 2x \Rightarrow$$

$$y' = \sqrt[4]{\frac{x^2 + 1}{x^2 - 1}} \cdot \frac{1}{2} \left(\frac{x}{x^2 + 1} - \frac{x}{x^2 - 1} \right) = \frac{1}{2} \sqrt[4]{\frac{x^2 + 1}{x^2 - 1}} \left(\frac{-2x}{x^4 - 1} \right) = \frac{x}{1 - x^4} \sqrt[4]{\frac{x^2 + 1}{x^2 - 1}}$$

$$43. y = x^x \Rightarrow \ln y = \ln x^x \Rightarrow \ln y = x \ln x \Rightarrow y'/y = x(1/x) + (\ln x) \cdot 1 \Rightarrow$$

$$y' = y(1 + \ln x) \Rightarrow y' = x^x(1 + \ln x)$$

$$44. y = x^{1/x} \Rightarrow \ln y = \frac{1}{x} \ln x \Rightarrow \frac{y'}{y} = \frac{1}{x} \left(\frac{1}{x} \right) + (\ln x) \left(-\frac{1}{x^2} \right) \Rightarrow y' = x^{1/x} \frac{1 - \ln x}{x^2}$$

$$45. y = x^{\sin x} \Rightarrow \ln y = \ln x^{\sin x} \Rightarrow \ln y = \sin x \ln x \Rightarrow \frac{y'}{y} = (\sin x) \cdot \frac{1}{x} + (\ln x)(\cos x) \Rightarrow$$

$$y' = y \left(\frac{\sin x}{x} + \ln x \cos x \right) \Rightarrow y' = x^{\sin x} \left(\frac{\sin x}{x} + \ln x \cos x \right)$$

$$46. y = (\sin x)^x \Rightarrow \ln y = x \ln(\sin x) \Rightarrow \frac{y'}{y} = x \cdot \frac{1}{\sin x} \cdot \cos x + [\ln(\sin x)] \cdot 1 \Rightarrow$$

$$y' = (\sin x)^x [x \cot x + \ln(\sin x)]$$

$$47. y = (\ln x)^x \Rightarrow \ln y = \ln(\ln x)^x \Rightarrow \ln y = x \ln \ln x \Rightarrow \frac{y'}{y} = x \cdot \frac{1}{\ln x} \cdot \frac{1}{x} + (\ln \ln x) \cdot 1 \Rightarrow$$

$$y' = y \left(\frac{x}{x \ln x} + \ln \ln x \right) \Rightarrow y' = (\ln x)^x \left(\frac{1}{\ln x} + \ln \ln x \right)$$

$$48. y = x^{\ln x} \Rightarrow \ln y = \ln x \ln x = (\ln x)^2 \Rightarrow \frac{y'}{y} = 2 \ln x \left(\frac{1}{x} \right) \Rightarrow y' = x^{\ln x} \left(\frac{2 \ln x}{x} \right)$$

$$49. y = x^{e^x} \Rightarrow \ln y = e^x \ln x \Rightarrow \frac{y'}{y} = e^x \cdot \frac{1}{x} + (\ln x) \cdot e^x \Rightarrow y' = x^{e^x} e^x \left(\ln x + \frac{1}{x} \right)$$

50. $y = (\ln x)^{\cos x} \Rightarrow \ln y = \cos x \ln(\ln x) \Rightarrow \frac{y'}{y} = \cos x \cdot \frac{1}{\ln x} \cdot \frac{1}{x} + (\ln \ln x)(-\sin x) \Rightarrow$

$$y' = (\ln x)^{\cos x} \left(\frac{\cos x}{x \ln x} - \sin x \ln \ln x \right)$$

$$\mathbf{51.} \quad y = \ln(x^2 + y^2) \Rightarrow y' = \frac{1}{x^2 + y^2} \frac{d}{dx}(x^2 + y^2) \Rightarrow y' = \frac{2x + 2yy'}{x^2 + y^2} \Rightarrow x^2y' + y^2y' = 2x + 2yy'$$

$$\Rightarrow x^2 y' + y^2 y' - 2y y' = 2x \quad \Rightarrow (x^2 + y^2 - 2y) y' = 2x \quad \Rightarrow y' = \frac{2x}{x^2 + y^2 - 2y}$$

$$\mathbf{52.} \quad x^y = y^x \quad \Rightarrow \quad y \ln x = x \ln y \quad \Rightarrow \quad y \cdot \frac{1}{x} + (\ln x) \cdot y' = x \cdot \frac{1}{y} \cdot y' + \ln y \quad \Rightarrow \quad y' \ln x - \frac{x}{y} y' = \ln y - \frac{y}{x} \quad \Rightarrow$$

$$y' = \frac{\ln y - y/x}{\ln x - x/y}$$

53. $f(x) = \ln(x-1) \Rightarrow f'(x) = 1/(x-1) = (x-1)^{-1} \Rightarrow f''(x) = -(x-1)^{-2} \Rightarrow$
 $f'''(x) = 2(x-1)^{-3} \Rightarrow f^{(4)}(x) = -2 \cdot 3(x-1)^{-4} \Rightarrow \cdots \Rightarrow$

$$f^{(n)}(x) = (-1)^{n-1} \cdot 2 \cdot 3 \cdot 4 \cdot \dots \cdot (n-1)(x-1)^{-n} = (-1)^{n-1} \frac{(n-1)!}{(x-1)^n}$$

54. $y = x^8 \ln x$, so $D^9 y = D^8 y' = D^8 (8x^7 \ln x + x^7)$. But the eighth derivative of x^7 is 0, so we now have

$$\begin{aligned} D^8(8x^7 \ln x) &= D^7(8 \cdot 7x^6 \ln x + 8x^6) = D^7(8 \cdot 7x^6 \ln x) \\ &= D^6(8 \cdot 7 \cdot 6x^5 \ln x) = \cdots = D(8!x^0 \ln x) = 8!/x. \end{aligned}$$

From the graph, it appears that the curves $y = (x - 4)^2$ and $y = \ln x$ intersect just to the left of $x = 3$ and to the right of $x = 5$, at about $x = 5.3$. Let $f(x) = \ln x - (x - 4)^2$. Then $f'(x) = 1/x - 2(x - 4)$ so Newton's Method says that

$$x_{n+1} = x_n - f(x_n)/f'(x_n) = x_n - \frac{\ln x_n - (x_n - 4)^2}{1/x_n - 2(x_n - 4)}.$$
 Taking

$x_0 = 3$, we get $x_1 \approx 2.957738$, $x_2 \approx 2.958516 \approx x_3$, so the first root is 2.958516, to six decimal places. Taking $x_0 = 5$, we get $x_1 \approx 5.290755$, $x_2 \approx 5.290718 \approx x_3$, so the second (and final) root is 5.290718, to six decimal places.

We use Newton's Method with $f(x) = \ln(4 - x^2) - x$ and

$$f'(x) = \frac{1}{4-x^2}(-2x) - 1 = -1 - \frac{2x}{4-x^2}.$$
 The formula is

$x_{n+1} = x_n - f(x_n)/f'(x_n)$. From the graphs it seems that the roots occur at approximately $x = -1.9$ and $x = 1.1$. However, if we use

$x_1 = -1.9$ as an initial approximation to the first root, we get

$x_2 \approx -2.009611$, and $f(x) = \ln(x - 2)^2 - x$ is undefined at this point,

making it impossible to calculate x_3 . We must use a more accurate first estimate, such as $x_1 = -1.95$. With this approximation, we get $x_1 = -1.95$, $x_2 \approx -1.1967495$, $x_3 \approx -1.964760$, $x_4 \approx x_5 \approx -1.964636$. Calculating the second root gives $x_1 = 1.1$, $x_2 \approx 1.058649$, $x_3 \approx 1.058007$, $x_4 \approx x_5 \approx 1.058006$. So, correct to six decimal places, the two roots of the equation $\ln(4 - x^2) = x$ are $x = -1.964636$ and $x = 1.058006$.

$$57. f(x) = \frac{\ln x}{\sqrt{x}} \Rightarrow f'(x) = \frac{\sqrt{x}(1/x) - (\ln x)[1/(2\sqrt{x})]}{x} = \frac{2 - \ln x}{2x^{3/2}} \Rightarrow$$

$$f''(x) = \frac{2x^{3/2}(-1/x) - (2 - \ln x)(3x^{1/2})}{4x^3} = \frac{3\ln x - 8}{4x^{5/2}} > 0 \Leftrightarrow \ln x > \frac{8}{3} \Leftrightarrow x > e^{8/3}, \text{ so } f \text{ is CU}$$

on $(e^{8/3}, \infty)$ and CD on $(0, e^{8/3})$. The inflection point is $(e^{8/3}, \frac{8}{3}e^{-4/3})$.

$$58. f(x) = x \ln x, f'(x) = \ln x + 1 = 0 \text{ when } \ln x = -1 \Leftrightarrow x = e^{-1}. f'(x) > 0 \Leftrightarrow \ln x + 1 > 0 \Leftrightarrow \ln x > -1 \Leftrightarrow x > 1/e. f'(x) < 0 \Leftrightarrow \ln x + 1 < 0 \Leftrightarrow x < 1/e. \text{ Therefore, there is an absolute minimum value of } f(1/e) = (1/e) \ln(1/e) = -1/e.$$

$$59. y = f(x) = \ln(\sin x)$$

$$\text{A. } D = \{x \in \mathbb{R} \mid \sin x > 0\} = \bigcup_{n=-\infty}^{\infty} (2n\pi, (2n+1)\pi) \\ = \dots \cup (-4\pi, -3\pi) \cup (-2\pi, -\pi) \cup (0, \pi) \cup (2\pi, 3\pi) \cup \dots$$

B. No y -intercept; x -intercepts: $f(x) = 0 \Leftrightarrow \ln(\sin x) = 0 \Leftrightarrow \sin x = e^0 = 1 \Leftrightarrow x = 2n\pi + \frac{\pi}{2}$ for each integer n . C. f is periodic with period 2π . D. $\lim_{x \rightarrow (2n\pi)^+} f(x) = -\infty$ and $\lim_{x \rightarrow [(2n+1)\pi]^-} f(x) = -\infty$, so

the lines $x = n\pi$ are VAs for all integers n . E. $f'(x) = \frac{\cos x}{\sin x} = \cot x$, so $f'(x) > 0$ when $2n\pi < x < 2n\pi + \frac{\pi}{2}$ for each integer n , and $f'(x) < 0$ when $2n\pi + \frac{\pi}{2} < x < (2n+1)\pi$. Thus, f is increasing on $(2n\pi, 2n\pi + \frac{\pi}{2})$ and decreasing on $(2n\pi + \frac{\pi}{2}, (2n+1)\pi)$ for each integer n . F. Local maximum values $f(2n\pi + \frac{\pi}{2}) = 0$, no local minimum. G. $f''(x) = -\csc^2 x < 0$, so f is CD on $(2n\pi, (2n+1)\pi)$ for each integer n . No IP

H.

$$60. y = \ln(\tan^2 x) \quad \text{A. } D = \{x \mid x \neq n\pi/2\} \quad \text{B. } x\text{-intercepts } n\pi + \frac{\pi}{4}, \text{ no } y\text{-intercept.} \quad \text{C. } f(-x) = f(x), \text{ so the curve is symmetric about the } y\text{-axis. Also } f(x + \pi) = f(x), \text{ so } f \text{ is periodic with period } \pi, \text{ and we consider parts D-G only for } -\frac{\pi}{2} < x < \frac{\pi}{2}. \quad \text{D. } \lim_{x \rightarrow 0} \ln(\tan^2 x) = -\infty \text{ and } \lim_{x \rightarrow (\pi/2)^-} \ln(\tan^2 x) = \infty.$$

$$\lim_{x \rightarrow (-\pi/2)^+} \ln(\tan^2 x) = \infty, \text{ so } x = 0, x = \pm \frac{\pi}{2} \text{ are VA.} \quad \text{E. } f'(x) = \frac{2 \tan x \sec^2 x}{\tan^2 x} = 2 \frac{\sec^2 x}{\tan x} > 0 \Leftrightarrow$$

$\tan x > 0 \Leftrightarrow 0 < x < \frac{\pi}{2}$, so f is increasing on $(0, \frac{\pi}{2})$ and decreasing on $(-\frac{\pi}{2}, 0)$. F. No maximum or minimum

$$\text{G. } f'(x) = \frac{2}{\sin x \cos x} = \frac{4}{\sin 2x} \Rightarrow f''(x) = \frac{-8 \cos 2x}{\sin^2 2x} < 0$$

$\Leftrightarrow \cos 2x > 0 \Leftrightarrow -\frac{\pi}{4} < x < \frac{\pi}{4}$, so f is CD on $(-\frac{\pi}{4}, 0)$ and $(0, \frac{\pi}{4})$ and CU on $(-\frac{\pi}{2}, -\frac{\pi}{4})$ and $(\frac{\pi}{4}, \frac{\pi}{2})$. IP are $(\pm \frac{\pi}{4}, 0)$.

H.

61. $y = f(x) = \ln(1 + x^2)$ A. $D = \mathbb{R}$ B. Both intercepts are 0. C. $f(-x) = f(x)$, so the curve is symmetric about the y -axis. D. $\lim_{x \rightarrow \pm\infty} \ln(1 + x^2) = \infty$, no asymptotes. E. $f'(x) = \frac{2x}{1 + x^2} > 0 \Leftrightarrow$

$x > 0$, so f is increasing on $(0, \infty)$ and decreasing on $(-\infty, 0)$.

F. $f(0) = 0$ is a local and absolute minimum.

G. $f''(x) = \frac{2(1 + x^2) - 2x(2x)}{(1 + x^2)^2} = \frac{2(1 - x^2)}{(1 + x^2)^2} > 0 \Leftrightarrow$

$|x| < 1$, so f is CU on $(-1, 1)$, CD on $(-\infty, -1)$ and $(1, \infty)$. IP $(1, \ln 2)$ and $(-1, \ln 2)$.

62. $y = f(x) = \ln(x^2 - 3x + 2) = \ln[(x - 1)(x - 2)]$

A. $D = \{x \text{ in } \mathbb{R}: x^2 - 3x + 2 > 0\} = (-\infty, 1) \cup (2, \infty)$.

B. y -intercept: $f(0) = \ln 2$; x -intercepts: $f(x) = 0 \Leftrightarrow x^2 - 3x + 2 = e^0 \Leftrightarrow x^2 - 3x + 1 = 0 \Leftrightarrow$

$x = \frac{3 \pm \sqrt{5}}{2} \Rightarrow x \approx 0.38, 2.62$ C. No symmetry D. $\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 2^+} f(x) = -\infty$, so $x = 1$ and

$x = 2$ are VAs. No HA. E. $f'(x) = \frac{2x - 3}{x^2 - 3x + 2} = \frac{2(x - 3/2)}{(x - 1)(x - 2)}$, so $f'(x) < 0$ for $x < 1$ and $f'(x) > 0$ for $x > 2$. Thus, f is decreasing on $(-\infty, 1)$ and increasing on $(2, \infty)$. F. No extreme values

G. $f''(x) = \frac{(x^2 - 3x + 2) \cdot 2 - (2x - 3)^2}{(x^2 - 3x + 2)^2}$
 $= \frac{2x^2 - 6x + 4 - 4x^2 + 12x - 9}{(x^2 - 3x + 2)^2}$
 $= \frac{-2x^2 + 6x - 5}{(x^2 - 3x + 2)^2}$

The numerator is negative for all x and the denominator is positive, so $f''(x) < 0$ for all x in the domain of f . Thus, f is CD on $(-\infty, 1)$ and $(2, \infty)$. No IP

63. We use the CAS to calculate $f'(x) = \frac{2 + \sin x + x \cos x}{2x + x \sin x}$ and

$f''(x) = \frac{2x^2 \sin x + 4 \sin x - \cos^2 x + x^2 + 5}{x^2(\cos^2 x - 4 \sin x - 5)}$. From the graphs, it

seems that $f' > 0$ (and so f is increasing) on approximately the intervals $(0, 2.7)$, $(4.5, 8.2)$ and $(10.9, 14.3)$. It seems that f'' changes sign (indicating inflection points) at $x \approx 3.8, 5.7, 10.0$ and 12.0 .

Looking back at the graph of $f(x) = \ln(2x + x \sin x)$, this implies that the inflection points have approximate coordinates $(3.8, 1.7)$, $(5.7, 2.1)$, $(10.0, 2.7)$, and $(12.0, 2.9)$.

64. We see that if $c \leq 0$, $f(x) = \ln(x^2 + c)$ is only defined for $x^2 > -c \Rightarrow |x| > \sqrt{-c}$, and

$\lim_{x \rightarrow \sqrt{-c}^+} f(x) = \lim_{x \rightarrow -\sqrt{-c}^-} f(x) = -\infty$, since $\ln y \rightarrow -\infty$ as $y \rightarrow 0$. Thus, for $c < 0$, there are vertical

asymptotes at $x = \pm\sqrt{-c}$, and as c decreases (that is, $|c|$ increases), the asymptotes get further apart. For $c = 0$,

$\lim_{x \rightarrow 0} f(x) = -\infty$, so there is a vertical asymptote at $x = 0$. If $c > 0$, there is no asymptote. To find the maxima,

minima, and inflection points, we differentiate: $f(x) = \ln(x^2 + c) \Rightarrow f'(x) = \frac{1}{x^2 + c} (2x)$, so by the First Derivative Test there is a local and absolute minimum at $x = 0$. Differentiating again, we get

$$f''(x) = \frac{1}{x^2 + c} (2) + 2x \left[- (x^2 + c)^{-2} (2x) \right] = \frac{2(c - x^2)}{(x^2 + c)^2}. \text{ Now}$$

if $c \leq 0$, this is always negative, so f is concave down on both of the intervals on which it is defined. If $c > 0$, then f'' changes sign when

$$c = x^2 \Leftrightarrow x = \pm\sqrt{c}. \text{ So for } c > 0 \text{ there are inflection points at}$$

$\pm\sqrt{c}$, and as c increases, the inflection points get further apart.

$$65. \int_2^4 \frac{3}{x} dx = 3 \int_2^4 \frac{1}{x} dx = 3 \left[\ln |x| \right]_2^4 = 3(\ln 4 - \ln 2) = 3 \ln \frac{4}{2} = 3 \ln 2$$

$$66. \int_1^2 \frac{4 + u^2}{u^3} du = \int_1^2 (4u^{-3} + u^{-1}) du = \left[\frac{4}{-2} u^{-2} + \ln |u| \right]_1^2 = \left[\frac{-2}{u^2} + \ln u \right]_1^2 \\ = \left(-\frac{1}{2} + \ln 2 \right) - \left(-2 + \ln 1 \right) = \frac{3}{2} + \ln 2$$

$$67. \int_1^2 \frac{dt}{8 - 3t} = \left[-\frac{1}{3} \ln |8 - 3t| \right]_1^2 = -\frac{1}{3} \ln 2 - \left(-\frac{1}{3} \ln 5 \right) = \frac{1}{3} (\ln 5 - \ln 2) = \frac{1}{3} \ln \frac{5}{2}$$

Or: Let $u = 8 - 3t$. Then $du = -3 dt$, so

$$\int_1^2 \frac{dt}{8 - 3t} = \int_5^2 \frac{-\frac{1}{3} du}{u} = \left[-\frac{1}{3} \ln |u| \right]_5^2 = -\frac{1}{3} \ln 2 - \left(-\frac{1}{3} \ln 5 \right) = \frac{1}{3} (\ln 5 - \ln 2) = \frac{1}{3} \ln \frac{5}{2}.$$

$$68. \int_4^9 \left(\sqrt{x} + \frac{1}{\sqrt{x}} \right)^2 dx = \int_4^9 \left(x + 2 + \frac{1}{x} \right) dx = \left[\frac{1}{2} x^2 + 2x + \ln x \right]_4^9 = \frac{81}{2} + 18 + \ln 9 - (8 + 8 + \ln 4) \\ = \frac{85}{2} + \ln \frac{9}{4}$$

$$69. \int_1^e \frac{x^2 + x + 1}{x} dx = \int_1^e \left(x + 1 + \frac{1}{x} \right) dx = \left[\frac{1}{2} x^2 + x + \ln x \right]_1^e = \left(\frac{1}{2} e^2 + e + 1 \right) - \left(\frac{1}{2} + 1 + 0 \right) \\ = \frac{1}{2} e^2 + e - \frac{1}{2}$$

$$70. \text{ Let } u = \ln x. \text{ Then } du = \frac{1}{x} dx, \text{ so } \int_e^6 \frac{dx}{x \ln x} = \int_1^{\ln 6} \frac{1}{u} du = \left[\ln |u| \right]_1^{\ln 6} = \ln \ln 6 - \ln 1 = \ln \ln 6$$

$$71. \text{ Let } u = 6x - x^3. \text{ Then } du = (6 - 3x^2) dx = 3(2 - x^2) dx, \text{ so}$$

$$\int \frac{2 - x^2}{6x - x^3} dx = \int \frac{\frac{1}{3} du}{u} = \frac{1}{3} \ln |u| + C = \frac{1}{3} \ln |6x - x^3| + C.$$

$$72. \text{ Let } u = 2 + \sin x. \text{ Then } du = \cos x dx, \text{ so}$$

$$\int \frac{\cos x}{2 + \sin x} dx = \int \frac{1}{u} du = \ln |u| + C = \ln |2 + \sin x| + C = \ln(2 + \sin x) + C \quad [\text{since } 2 + \sin x > 0].$$

73. Let $u = \ln x$. Then $du = \frac{dx}{x} \Rightarrow \int \frac{(\ln x)^2}{x} dx = \int u^2 du = \frac{1}{3}u^3 + C = \frac{1}{3}(\ln x)^3 + C$.

74. Let $u = e^x + 1$. Then $du = e^x dx$, so $\int \frac{e^x}{e^x + 1} dx = \int \frac{du}{u} = \ln |u| + C = \ln(e^x + 1) + C$.

75. $\int_1^{10} 10^t dt = \left[\frac{10^t}{\ln 10} \right]_1^{10} = \frac{10^{10}}{\ln 10} - \frac{10^1}{\ln 10} = \frac{10^{10} - 10}{\ln 10} = \frac{9999999990}{\ln 10}$

76. Let $u = x^2$. Then $du = 2x dx$, so $\int x 2x^2 dx = \frac{1}{2} \int 2^u du = \frac{1}{2} \frac{2^u}{\ln 2} + C = \frac{1}{2 \ln 2} 2^{x^2} + C$.

77. (a) $\frac{d}{dx} (\ln |\sin x| + C) = \frac{1}{\sin x} \cos x = \cot x$

(b) Let $u = \sin x$. Then $du = \cos x dx$, so $\int \cot x dx = \int \frac{\cos x}{\sin x} dx = \int \frac{du}{u} = \ln |u| + C = \ln |\sin x| + C$.

78. Let $u = x - 2$. Then the area is

$$A = - \int_{-4}^{-1} \frac{2}{x-2} dx = -2 \int_{-6}^{-3} \frac{du}{u} = \left[-2 \ln |u| \right]_{-6}^{-3} = -2 \ln 3 + 2 \ln 6 = 2 \ln 2 \approx 1.386.$$

79. The cross-sectional area is $\pi(1/\sqrt{x+1})^2 = \pi/(x+1)$. Therefore, the volume is

$$\int_0^1 \frac{\pi}{x+1} dx = \pi [\ln(x+1)]_0^1 = \pi(\ln 2 - \ln 1) = \pi \ln 2.$$

80. Using cylindrical shells, we get $V = \int_0^3 \frac{2\pi x}{x^2+1} dx = \pi [\ln(1+x^2)]_0^3 = \pi \ln 10$.

81. $W = \int_{V_1}^{V_2} P dV = \int_{600}^{1000} \frac{C}{V} dV = C \int_{600}^{1000} \frac{1}{V} dV = C [\ln |V|]_{600}^{1000}$
 $= C(\ln 1000 - \ln 600) = C \ln \frac{1000}{600} = C \ln \frac{5}{3}$

Initially, $PV = C$, where $P = 150$ kPa and $V = 600$ cm³, so $C = (150)(600) = 90,000$. Thus,

$$W = 90,000 \ln \frac{5}{3} \approx 45,974 \text{ kPa} \cdot \text{cm}^3 = 45,974(10^3 \text{ Pa})(10^{-6} \text{ m}^3) = 45,974 \text{ Pa} \cdot \text{m}^3 = 45,974 \text{ N} \cdot \text{m}$$

$$[\text{Pa} = \text{N/m}^2] \quad = 45,974 \text{ J}$$

82. $f''(x) = x^{-2}, x > 0 \Rightarrow f'(x) = -1/x + C \Rightarrow f(x) = -\ln x + Cx + D$. $0 = f(1) = C + D$ and

$$0 = f(2) = -\ln 2 + 2C + D = -\ln 2 + 2C - C = -\ln 2 + C \Rightarrow C = \ln 2 \text{ and } D = -\ln 2. \text{ So}$$

$$f(x) = -\ln x + (\ln 2)x - \ln 2.$$

83. $f(x) = 2x + \ln x \Rightarrow f'(x) = 2 + 1/x$. If $g = f^{-1}$, then $f(1) = 2 \Rightarrow g(2) = 1$, so

$$g'(2) = 1/f'(g(2)) = 1/f'(1) = \frac{1}{3}.$$

84. $f(x) = e^x + \ln x \Rightarrow f'(x) = e^x + 1/x$. $h = f^{-1}$ and $f(1) = e \Rightarrow h(e) = 1$, so

$$h'(e) = 1/f'(1) = 1/(e+1).$$

85. The curve and the line will determine a region when they intersect at two or more points. So we solve the equation $x/(x^2 + 1) = mx \Rightarrow x = 0$ or $mx^2 + m - 1 = 0 \Rightarrow x = 0$ or

$$x = \frac{\pm \sqrt{-4(m)(m-1)}}{2m} = \pm \sqrt{\frac{1}{m} - 1}. \text{ Note that if } m = 1, \text{ this}$$

has only the solution $x = 0$, and no region is determined. But if

$$1/m - 1 > 0 \Leftrightarrow 1/m > 1 \Leftrightarrow 0 < m < 1, \text{ then there are two}$$

solutions. [Another way of seeing this is to observe that the slope of the tangent to $y = x/(x^2 + 1)$ at the origin is

$y' = 1$ and therefore we must have $0 < m < 1$.] Note that we cannot just integrate between the positive and

negative roots, since the curve and the line cross at the origin. Since mx and $x/(x^2 + 1)$ are both odd functions,

the total area is twice the area between the curves on the interval $[0, \sqrt{1/m - 1}]$. So the total area enclosed is

$$\begin{aligned} 2 \int_0^{\sqrt{1/m-1}} \left[\frac{x}{x^2+1} - mx \right] dx &= 2 \left[\frac{1}{2} \ln(x^2+1) - \frac{1}{2} mx^2 \right]_0^{\sqrt{1/m-1}} \\ &= \left[\ln \left(\frac{1}{m} - 1 + 1 \right) - m \left(\frac{1}{m} - 1 \right) \right] - (\ln 1 - 0) \\ &= \ln \left(\frac{1}{m} \right) + m - 1 = m - \ln m - 1 \end{aligned}$$

86. (a) Let $f(x) = \ln x \Rightarrow f'(x) = 1/x \Rightarrow f''(x) = -1/x^2$. The linear approximation to $\ln x$ near 1 is $\ln x \approx f(1) + f'(1)(x-1) = \ln 1 + \frac{1}{1}(x-1) = x-1$.

(b)

(c)

From the graph, it appears that the linear approximation is accurate to within 0.1 for x between about 0.62 and 1.51.

87. If $f(x) = \ln(1+x)$, then $f'(x) = \frac{1}{1+x}$, so $f'(0) = 1$.

$$\text{Thus, } \lim_{x \rightarrow 0} \frac{\ln(1+x)}{x} = \lim_{x \rightarrow 0} \frac{f(x)}{x} = \lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x - 0} = f'(0) = 1.$$

88. Let $m = n/x$. Then $n = xm$, and as $n \rightarrow \infty$, $m \rightarrow \infty$.

$$\text{Therefore, } \lim_{n \rightarrow \infty} \left(1 + \frac{x}{n} \right)^n = \lim_{m \rightarrow \infty} \left(1 + \frac{1}{m} \right)^{mx} = \left[\lim_{m \rightarrow \infty} \left(1 + \frac{1}{m} \right)^m \right]^x = e^x \text{ by Equation 9.}$$

7.2* The Natural Logarithmic Function

$$1. \ln \frac{x^3 y}{z^2} = \ln x^3 y - \ln z^2 = \ln x^3 + \ln y - \ln z^2 = 3 \ln x + \ln y - 2 \ln z$$

$$2. \ln \sqrt{a(b^2 + c^2)} = \ln(a(b^2 + c^2))^{1/2} = \frac{1}{2} \ln(a(b^2 + c^2)) = \frac{1}{2} [\ln a + \ln(b^2 + c^2)] \\ = \frac{1}{2} \ln a + \frac{1}{2} \ln(b^2 + c^2)$$

$$3. \ln(uv)^{10} = 10 \ln(uv) = 10(\ln u + \ln v) = 10 \ln u + 10 \ln v$$

$$4. \ln \frac{3x^2}{(x+1)^5} = \ln 3x^2 - \ln(x+1)^5 = \ln 3 + \ln x^2 - 5 \ln(x+1) = \ln 3 + 2 \ln x - 5 \ln(x+1)$$

$$5. 2 \ln 4 - \ln 2 = \ln 4^2 - \ln 2 = \ln 16 - \ln 2 = \ln \frac{16}{2} = \ln 8$$

$$6. \ln 3 + \frac{1}{3} \ln 8 = \ln 3 + \ln 8^{1/3} = \ln 3 + \ln 2 = \ln(3 \cdot 2) = \ln 6$$

$$7. \frac{1}{2} \ln x - 5 \ln(x^2 + 1) = \ln x^{1/2} - \ln(x^2 + 1)^5 = \ln \frac{\sqrt{x}}{(x^2 + 1)^5}$$

$$8. \ln x + a \ln y - b \ln z = \ln x + \ln y^a - \ln z^b = \ln(x \cdot y^a) - \ln z^b = \ln(xy^a/z^b)$$

9. Reflect the graph of $y = \ln x$ about the x -axis to obtain the graph of $y = -\ln x$.

$$y = \ln x$$

$$y = -\ln x$$

10. Reflect the portion of the graph of $y = \ln x$ to the right of the y -axis about the y -axis. The graph of $y = \ln |x|$ is that reflection in addition to the original portion.

$$y = \ln x$$

$$y = \ln |x|$$

11. $y = \ln x$

$$y = \ln(x+3)$$

12. $y = \ln(x-2)$

$$y = 1 + \ln(x-2)$$

$$13. f(x) = \sqrt{x} \ln x \Rightarrow f'(x) = \frac{1}{2\sqrt{x}} \ln x + \sqrt{x} \left(\frac{1}{x} \right) = \frac{\ln x + 2}{2\sqrt{x}}$$

$$14. f(x) = \ln(x^2 + 10) \Rightarrow f'(x) = \frac{1}{x^2 + 10} \frac{d}{dx} (x^2 + 10) = \frac{2x}{x^2 + 10}$$

$$15. f(\theta) = \ln(\cos \theta) \Rightarrow f'(\theta) = \frac{1}{\cos \theta} \frac{d}{d\theta} (\cos \theta) = \frac{-\sin \theta}{\cos \theta} = -\tan \theta$$

$$16. f(x) = \cos(\ln x) \Rightarrow f'(x) = -\sin(\ln x) \cdot \frac{1}{x} = \frac{-\sin(\ln x)}{x}$$

$$17. f(x) = \sqrt[5]{\ln x} = (\ln x)^{1/5} \Rightarrow f'(x) = \frac{1}{5}(\ln x)^{-4/5} \frac{d}{dx} (\ln x) = \frac{1}{5(\ln x)^{4/5}} \cdot \frac{1}{x} = \frac{1}{5x \sqrt[5]{(\ln x)^4}}$$

$$18. f(x) = \ln \sqrt[5]{x} = \ln x^{1/5} = \frac{1}{5} \ln x \Rightarrow f'(x) = \frac{1}{5} \cdot \frac{1}{x} = \frac{1}{5x}$$

$$19. g(x) = \ln \frac{a-x}{a+x} = \ln(a-x) - \ln(a+x) \Rightarrow$$

$$g'(x) = \frac{1}{a-x}(-1) - \frac{1}{a+x} = \frac{-(a+x) - (a-x)}{(a-x)(a+x)} = \frac{-2a}{a^2 - x^2}$$

$$20. h(x) = \ln(x + \sqrt{x^2 - 1}) \Rightarrow$$

$$h'(x) = \frac{1}{x + \sqrt{x^2 - 1}} \left(1 + \frac{x}{\sqrt{x^2 - 1}} \right) = \frac{1}{x + \sqrt{x^2 - 1}} \cdot \frac{\sqrt{x^2 - 1} + x}{\sqrt{x^2 - 1}} = \frac{1}{\sqrt{x^2 - 1}}$$

$$21. f(u) = \frac{\ln u}{1 + \ln(2u)} \Rightarrow$$

$$\begin{aligned} f'(u) &= \frac{[1 + \ln(2u)] \cdot \frac{1}{u} - \ln u \cdot \frac{1}{2u} \cdot 2}{[1 + \ln(2u)]^2} = \frac{\frac{1}{u} [1 + \ln(2u) - \ln u]}{[1 + \ln(2u)]^2} \\ &= \frac{1 + (\ln 2 + \ln u) - \ln u}{u [1 + \ln(2u)]^2} = \frac{1 + \ln 2}{u [1 + \ln(2u)]^2} \end{aligned}$$

$$22. f(t) = \frac{1 + \ln t}{1 - \ln t} \Rightarrow$$

$$f'(t) = \frac{(1 - \ln t)(1/t) - (1 + \ln t)(-1/t)}{(1 - \ln t)^2} = \frac{(1/t)[(1 - \ln t) + (1 + \ln t)]}{(1 - \ln t)^2} = \frac{2}{t(1 - \ln t)^2}$$

$$23. F(t) = \ln \frac{(2t+1)^3}{(3t-1)^4} = \ln(2t+1)^3 - \ln(3t-1)^4 = 3 \ln(2t+1) - 4 \ln(3t-1) \Rightarrow$$

$$F'(t) = 3 \cdot \frac{1}{2t+1} \cdot 2 - 4 \cdot \frac{1}{3t-1} \cdot 3 = \frac{6}{2t+1} - \frac{12}{3t-1}, \text{ or combined, } \frac{-6(t+3)}{(2t+1)(3t-1)}.$$

$$24. y = \ln(x^4 \sin^2 x) = \ln x^4 + \ln(\sin x)^2 = 4 \ln x + 2 \ln \sin x \Rightarrow y' = 4 \cdot \frac{1}{x} + 2 \cdot \frac{1}{\sin x} \cdot \cos x = \frac{4}{x} + 2 \cot x$$

$$25. y = \ln |2 - x - 5x^2| \Rightarrow y' = \frac{1}{2 - x - 5x^2} \cdot (-1 - 10x) = \frac{-10x - 1}{2 - x - 5x^2} \text{ or } \frac{10x + 1}{5x^2 + x - 2}$$

$$26. G(u) = \ln \sqrt{\frac{3u+2}{3u-2}} = \frac{1}{2} [\ln(3u+2) - \ln(3u-2)] \Rightarrow G'(u) = \frac{1}{2} \left(\frac{3}{3u+2} - \frac{3}{3u-2} \right) = \frac{-6}{9u^2 - 4}$$

$$27. y = \ln \left(\frac{x+1}{x-1} \right)^{3/5} = \frac{3}{5} [\ln(x+1) - \ln(x-1)] \Rightarrow y' = \frac{3}{5} \left(\frac{1}{x+1} - \frac{1}{x-1} \right) = \frac{-6}{5(x^2 - 1)}$$

$$28. y = (\ln \tan x)^2 \Rightarrow y' = 2(\ln \tan x) \cdot \frac{1}{\tan x} \cdot \sec^2 x = \frac{2(\ln \tan x) \sec^2 x}{\tan x}$$

$$29. y = \tan[\ln(ax + b)] \Rightarrow y' = \sec^2[\ln(ax + b)] \cdot \frac{1}{ax + b} \cdot a = \sec^2[\ln(ax + b)] \frac{a}{ax + b}$$

$$30. y = \ln|\tan 2x| \Rightarrow y' = \frac{2\sec^2 2x}{\tan 2x}$$

$$31. y = \ln \ln x \Rightarrow y' = \frac{1}{\ln x} \frac{d}{dx}(\ln x) = \frac{1}{\ln x} \cdot \frac{1}{x} = \frac{1}{x \ln x} \Rightarrow$$

$$y'' = -\frac{\frac{d}{dx}(x \ln x)}{(x \ln x)^2} \quad [\text{Reciprocal Rule}] = -\frac{x \cdot \frac{1}{x} + \ln x \cdot 1}{(x \ln x)^2} = -\frac{1 + \ln x}{(x \ln x)^2}$$

$$32. y = \frac{\ln x}{x^2} \Rightarrow y' = \frac{x^2(1/x) - (\ln x)(2x)}{(x^2)^2} = \frac{x(1 - 2 \ln x)}{x^4} = \frac{1 - 2 \ln x}{x^3} \Rightarrow$$

$$y'' = \frac{x^3(-2/x) - (1 - 2 \ln x)(3x^2)}{(x^3)^2} = \frac{x^2(-2 - 3 + 6 \ln x)}{x^6} = \frac{6 \ln x - 5}{x^4}$$

$$33. f(x) = \frac{x}{1 - \ln(x-1)} \Rightarrow$$

$$\begin{aligned} f'(x) &= \frac{[1 - \ln(x-1)] \cdot 1 - x \cdot \frac{-1}{x-1}}{[1 - \ln(x-1)]^2} = \frac{(x-1)[1 - \ln(x-1)] + x}{[1 - \ln(x-1)]^2} = \frac{x-1 - (x-1)\ln(x-1) + x}{(x-1)[1 - \ln(x-1)]^2} \\ &= \frac{2x-1 - (x-1)\ln(x-1)}{(x-1)[1 - \ln(x-1)]^2} \end{aligned}$$

$$\begin{aligned} \text{Dom}(f) &= \{x \mid x-1 > 0 \text{ and } 1 - \ln(x-1) \neq 0\} = \{x \mid x > 1 \text{ and } \ln(x-1) \neq 1\} \\ &= \{x \mid x > 1 \text{ and } x-1 \neq e^1\} = \{x \mid x > 1 \text{ and } x \neq 1+e\} = (1, 1+e) \cup (1+e, \infty) \end{aligned}$$

$$34. f(x) = \frac{1}{1 + \ln x} \Rightarrow f'(x) = -\frac{1/x}{(1 + \ln x)^2} \quad [\text{Reciprocal Rule}] = -\frac{1}{x(1 + \ln x)^2}.$$

$$\text{Dom}(f) = \{x \mid x > 0 \text{ and } \ln x \neq -1\} = \{x \mid x > 0 \text{ and } x \neq 1/e\} = (0, 1/e) \cup (1/e, \infty).$$

$$35. f(x) = \sqrt{1 - \ln x} \text{ is defined} \Leftrightarrow x > 0 \text{ [so that } \ln x \text{ is defined]} \text{ and } 1 - \ln x \geq 0$$

$$\Leftrightarrow x > 0 \text{ and } \ln x \leq 1 \Leftrightarrow 0 < x \leq e, \text{ so the domain of } f \text{ is } (0, e]. \text{ Now}$$

$$f'(x) = \frac{1}{2}(1 - \ln x)^{-1/2} \cdot \frac{d}{dx}(1 - \ln x) = \frac{1}{2\sqrt{1 - \ln x}} \cdot \left(-\frac{1}{x}\right) = \frac{-1}{2x\sqrt{1 - \ln x}}.$$

$$36. f(x) = \ln \ln \ln x \Rightarrow f'(x) = \frac{1}{\ln \ln x} \cdot \frac{1}{\ln x} \cdot \frac{1}{x}.$$

$$\text{Dom}(f) = \{x \mid \ln \ln x > 0\} = \{x \mid \ln x > 1\} = \{x \mid x > e\} = (e, \infty).$$

$$37. f(x) = \frac{x}{\ln x} \Rightarrow f'(x) = \frac{\ln x - x(1/x)}{(\ln x)^2} = \frac{\ln x - 1}{(\ln x)^2} \Rightarrow f'(e) = \frac{1-1}{1^2} = 0$$

$$38. f(t) = t \ln(4 + 3t) \Rightarrow f'(t) = t \cdot \frac{1}{4 + 3t} \cdot 3 + \ln(4 + 3t) = \frac{3t}{4 + 3t} + \ln(4 + 3t),$$

$$\text{so } f'(-1) = \frac{-3}{1} + \ln 1 = -3 + 0 = -3.$$

$$39. f(x) = \sin x + \ln x \Rightarrow f'(x) = \cos x + 1/x. \text{ This is reasonable,}$$

because the graph shows that f increases when f' is positive, and

$f'(x) = 0$ when f has a horizontal tangent.

$$40. f(x) = \ln(x^2 + x + 1) \Rightarrow f'(x) = \frac{1}{x^2 + x + 1} (2x + 1).$$

Notice from the graph that f is increasing when $f'(x)$ is positive.

$$41. y = \sin(2 \ln x) \Rightarrow y' = \cos(2 \ln x) \cdot \frac{2}{x}. \text{ At } (1, 0), y' = \cos 0 \cdot \frac{2}{1} = 2, \text{ so an equation of the tangent line is } y - 0 = 2 \cdot (x - 1), \text{ or } y = 2x - 2.$$

$$42. y = \ln(x^3 - 7) \Rightarrow y' = \frac{1}{x^3 - 7} \cdot 3x^2 \Rightarrow y'(2) = \frac{12}{8 - 7} = 12, \text{ so an equation of a tangent line at } (2, 0) \text{ is } y - 0 = 12(x - 2) \text{ or } y = 12x - 24.$$

$$43. y = \ln(x^2 + y^2) \Rightarrow y' = \frac{1}{x^2 + y^2} \frac{d}{dx}(x^2 + y^2) \Rightarrow y' = \frac{2x + 2yy'}{x^2 + y^2} \Rightarrow x^2 y' + y^2 y' = 2x + 2yy' \\ \Rightarrow x^2 y' + y^2 y' - 2yy' = 2x \Rightarrow (x^2 + y^2 - 2y)y' = 2x \Rightarrow y' = \frac{2x}{x^2 + y^2 - 2y}$$

$$44. \ln xy = \ln x + \ln y = y \sin x \Rightarrow 1/x + y'/y = y \cos x + y' \sin x \Rightarrow y'(1/y - \sin x) = y \cos x - 1/x \Rightarrow \\ y' = \frac{y \cos x - 1/x}{1/y - \sin x} = \left(\frac{y}{x}\right) \frac{xy \cos x - 1}{1 - y \sin x}$$

$$45. f(x) = \ln(x - 1) \Rightarrow f'(x) = 1/(x - 1) = (x - 1)^{-1} \Rightarrow f''(x) = -(x - 1)^{-2} \Rightarrow \\ f'''(x) = 2(x - 1)^{-3} \Rightarrow f^{(4)}(x) = -2 \cdot 3(x - 1)^{-4} \Rightarrow \dots \Rightarrow \\ f^{(n)}(x) = (-1)^{n-1} \cdot 2 \cdot 3 \cdot 4 \cdot \dots \cdot (n - 1)(x - 1)^{-n} = (-1)^{n-1} \frac{(n - 1)!}{(x - 1)^n}$$

$$46. y = x^8 \ln x, \text{ so } D^9 y = D^8 y' = D^8 (8x^7 \ln x + x^7). \text{ But the eighth derivative of } x^7 \text{ is 0, so we now have}$$

$$D^8 (8x^7 \ln x) = D^7 (8 \cdot 7x^6 \ln x + 8x^6) = D^7 (8 \cdot 7x^6 \ln x) \\ = D^6 (8 \cdot 7 \cdot 6x^5 \ln x) = \dots = D (8! x^0 \ln x) = 8!/x.$$

From the graph, it appears that the curves $y = (x - 4)^2$ and $y = \ln x$ intersect just to the left of $x = 3$ and to the right of $x = 5$, at about $x = 5.3$. Let $f(x) = \ln x - (x - 4)^2$. Then $f'(x) = 1/x - 2(x - 4)$, so Newton's Method says that

$$x_{n+1} = x_n - f(x_n)/f'(x_n) = x_n - \frac{\ln x_n - (x_n - 4)^2}{1/x_n - 2(x_n - 4)}.$$
 Taking

$x_0 = 3$, we get $x_1 \approx 2.957738$, $x_2 \approx 2.958516 \approx x_3$, so the first root is

2.958516, to six decimal places. Taking $x_0 = 5$, we get $x_1 \approx 5.290755$, $x_2 \approx 5.290718 \approx x_3$, so the second (and final) root is 5.290718, to six decimal places.

We use Newton's Method with $f(x) = \ln(4 - x^2) - x$ and

$$f'(x) = \frac{1}{4 - x^2}(-2x) - 1 = -1 - \frac{2x}{4 - x^2}.$$

The formula is

$$x_{n+1} = x_n - f(x_n)/f'(x_n).$$

From the graphs it seems that the roots

occur at approximately $x = -1.9$ and $x = 1.1$. However, if we use

$x_1 = -1.9$ as an initial approximation to the first root, we get

$x_2 \approx -2.009611$, and $f(x) = \ln(x - 2)^2 - x$ is undefined at this point,

making it impossible to calculate x_3 . We must use a more accurate first estimate, such as $x_1 = -1.95$. With this approximation, we get $x_1 = -1.95$, $x_2 \approx -1.1967495$, $x_3 \approx -1.964760$, $x_4 \approx x_5 \approx -1.964636$. Calculating the second root gives $x_1 = 1.1$, $x_2 \approx 1.058649$, $x_3 \approx 1.058007$, $x_4 \approx x_5 \approx 1.058006$. So, correct to six decimal places, the two roots of the equation $\ln(4 - x^2) = x$ are $x = -1.964636$ and $x = 1.058006$.

49. $y = f(x) = \ln(\sin x)$

A. $D = \{x \in \mathbb{R} \mid \sin x > 0\} = \bigcup_{n=-\infty}^{\infty} (2n\pi, (2n+1)\pi)$
 $= \dots \cup (-4\pi, -3\pi) \cup (-2\pi, -\pi) \cup (0, \pi) \cup (2\pi, 3\pi) \cup \dots$

B. No y -intercept; x -intercepts: $f(x) = 0 \Leftrightarrow \ln(\sin x) = 0 \Leftrightarrow \sin x = e^0 = 1 \Leftrightarrow x = 2n\pi + \frac{\pi}{2}$ for each integer n .

C. f is periodic with period 2π . D. $\lim_{x \rightarrow (2n\pi)^+} f(x) = -\infty$ and $\lim_{x \rightarrow [(2n+1)\pi]^-} f(x) = -\infty$, so

the lines $x = n\pi$ are VAs for all integers n . E. $f'(x) = \frac{\cos x}{\sin x} = \cot x$, so $f'(x) > 0$ when $2n\pi < x < 2n\pi + \frac{\pi}{2}$ for each integer n , and $f'(x) < 0$ when $2n\pi + \frac{\pi}{2} < x < (2n+1)\pi$. Thus, f is increasing on $(2n\pi, 2n\pi + \frac{\pi}{2})$ and

decreasing on $(2n\pi + \frac{\pi}{2}, (2n+1)\pi)$ for each integer n . F. Local maximum values $f(2n\pi + \frac{\pi}{2}) = 0$, no local

minimum. G. $f''(x) = -\csc^2 x < 0$, so f is CD on $(2n\pi, (2n+1)\pi)$ for each integer n . No IP

H.

50. $y = \ln(\tan^2 x)$ A. $D = \{x \mid x \neq n\pi/2\}$ B. x -intercepts $n\pi + \frac{\pi}{4}$, no y -intercept. C. $f(-x) = f(x)$, so the curve is symmetric about the y -axis. Also $f(x + \pi) = f(x)$, so f is periodic with period π , and we consider parts

D–G only for $-\frac{\pi}{2} < x < \frac{\pi}{2}$. D. $\lim_{x \rightarrow 0} \ln(\tan^2 x) = -\infty$ and $\lim_{x \rightarrow (\pi/2)^-} \ln(\tan^2 x) = \infty$,

$\lim_{x \rightarrow -(\pi/2)^+} \ln(\tan^2 x) = \infty$, so $x = 0$, $x = \pm \frac{\pi}{2}$ are VA. E. $f'(x) = \frac{2 \tan x \sec^2 x}{\tan^2 x} = 2 \frac{\sec^2 x}{\tan x} > 0 \Leftrightarrow$

$\tan x > 0 \Leftrightarrow 0 < x < \frac{\pi}{2}$, so f is increasing on $(0, \frac{\pi}{2})$ and decreasing on $(-\frac{\pi}{2}, 0)$. **F.** No maximum or minimum

$$\text{G. } f'(x) = \frac{2}{\sin x \cos x} = \frac{4}{\sin 2x} \Rightarrow f''(x) = \frac{-8 \cos 2x}{\sin^2 2x} < 0$$

$\Leftrightarrow \cos 2x > 0 \Leftrightarrow -\frac{\pi}{4} < x < \frac{\pi}{4}$, so f is CD on $(-\frac{\pi}{4}, 0)$ and $(0, \frac{\pi}{4})$ and CU on $(-\frac{\pi}{2}, -\frac{\pi}{4})$ and $(\frac{\pi}{4}, \frac{\pi}{2})$. IP are $(\pm \frac{\pi}{4}, 0)$.

51. $y = f(x) = \ln(1 + x^2)$ **A.** $D = \mathbb{R}$ **B.** Both intercepts are 0. **C.** $f(-x) = f(x)$, so the curve is symmetric

about the y -axis. **D.** $\lim_{x \rightarrow \pm\infty} \ln(1 + x^2) = \infty$, no asymptotes. **E.** $f'(x) = \frac{2x}{1 + x^2} > 0 \Leftrightarrow$

$x > 0$, so f is increasing on $(0, \infty)$ and decreasing on $(-\infty, 0)$.

F. $f(0) = 0$ is a local and absolute minimum.

$$\text{G. } f''(x) = \frac{2(1 + x^2) - 2x(2x)}{(1 + x^2)^2} = \frac{2(1 - x^2)}{(1 + x^2)^2} > 0 \Leftrightarrow$$

$|x| < 1$, so f is CU on $(-1, 1)$, CD on $(-\infty, -1)$ and $(1, \infty)$. IP $(1, \ln 2)$ and $(-1, \ln 2)$.

52. $y = f(x) = \ln(x^2 - 3x + 2) = \ln[(x - 1)(x - 2)]$

A. $D = \{x \text{ in } \mathbb{R} : x^2 - 3x + 2 > 0\} = (-\infty, 1) \cup (2, \infty)$.

B. y -intercept: $f(0) = \ln 2$; x -intercepts: $f(x) = 0 \Leftrightarrow x^2 - 3x + 2 = e^0 \Leftrightarrow x^2 - 3x + 1 = 0 \Leftrightarrow$

$$x = \frac{3 \pm \sqrt{5}}{2} \Rightarrow x \approx 0.38, 2.62 \quad \text{C. No symmetry} \quad \text{D. } \lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 2^+} f(x) = -\infty, \text{ so } x = 1 \text{ and}$$

$x = 2$ are VAs. No HA. **E.** $f'(x) = \frac{2x - 3}{x^2 - 3x + 2} = \frac{2(x - 3/2)}{(x - 1)(x - 2)}$, so $f'(x) < 0$ for $x < 1$ and $f'(x) > 0$

for $x > 2$. Thus, f is decreasing on $(-\infty, 1)$ and increasing on $(2, \infty)$. **F.** No extreme values

$$\begin{aligned} \text{G. } f''(x) &= \frac{(x^2 - 3x + 2) \cdot 2 - (2x - 3)^2}{(x^2 - 3x + 2)^2} \\ &= \frac{2x^2 - 6x + 4 - 4x^2 + 12x - 9}{(x^2 - 3x + 2)^2} \\ &= \frac{-2x^2 + 6x - 5}{(x^2 - 3x + 2)^2} \end{aligned}$$

The numerator is negative for all x and the denominator is positive,

so $f''(x) < 0$ for all x in the domain of f . Thus, f is CD on

$(-\infty, 1)$ and $(2, \infty)$. No IP

53. We use the CAS to calculate $f'(x) = \frac{2 + \sin x + x \cos x}{2x + x \sin x}$ and

$$f''(x) = \frac{2x^2 \sin x + 4 \sin x - \cos^2 x + x^2 + 5}{x^2(\cos^2 x - 4 \sin x - 5)}.$$

From the graphs, it seems that $f' > 0$ (and so f is increasing) on approximately the intervals $(0, 2.7)$, $(4.5, 8.2)$ and $(10.9, 14.3)$. It seems that f'' changes sign (indicating inflection points) at $x \approx 3.8, 5.7, 10.0$ and 12.0 .

Looking back at the graph of $f(x) = \ln(2x + x \sin x)$, this implies that the inflection points have approximate coordinates $(3.8, 1.7)$, $(5.7, 2.1)$, $(10.0, 2.7)$, and $(12.0, 2.9)$.

54. We see that if $c \leq 0$, $f(x) = \ln(x^2 + c)$ is only defined for $x^2 > -c \Rightarrow |x| > \sqrt{-c}$, and

$$\lim_{x \rightarrow \sqrt{-c}^+} f(x) = \lim_{x \rightarrow -\sqrt{-c}^-} f(x) = -\infty, \text{ since } \ln y \rightarrow -\infty \text{ as } y \rightarrow 0. \text{ Thus, for } c < 0, \text{ there are vertical}$$

asymptotes at $x = \pm\sqrt{-c}$, and as c decreases (that is, $|c|$ increases), the asymptotes get further apart. For $c = 0$,

$\lim_{x \rightarrow 0} f(x) = -\infty$, so there is a vertical asymptote at $x = 0$. If $c > 0$, there is no asymptote. To find the maxima,

minima, and inflection points, we differentiate: $f(x) = \ln(x^2 + c) \Rightarrow f'(x) = \frac{1}{x^2 + c} (2x)$, so by the First

Derivative Test there is a local and absolute minimum at $x = 0$. Differentiating again, we get

$$f''(x) = \frac{1}{x^2 + c} (2) + 2x \left[-(x^2 + c)^{-2} (2x) \right] = \frac{2(c - x^2)}{(x^2 + c)^2}.$$

Now if $c \leq 0$, this is always negative, so f is concave down on both of the intervals on which it is defined. If $c > 0$, then f'' changes sign when $c = x^2 \Leftrightarrow x = \pm\sqrt{c}$. So for $c > 0$ there are inflection points at $\pm\sqrt{c}$, and as c increases, the inflection points get further apart.

55. $y = (2x + 1)^5 (x^4 - 3)^6 \Rightarrow \ln y = \ln((2x + 1)^5 (x^4 - 3)^6) \Rightarrow$

$$\ln y = 5 \ln(2x + 1) + 6 \ln(x^4 - 3) \Rightarrow \frac{1}{y} y' = 5 \cdot \frac{1}{2x + 1} \cdot 2 + 6 \cdot \frac{1}{x^4 - 3} \cdot 4x^3 \Rightarrow$$

$$y' = y \left(\frac{10}{2x + 1} + \frac{24x^3}{x^4 - 3} \right) = (2x + 1)^5 (x^4 - 3)^6 \left(\frac{10}{2x + 1} + \frac{24x^3}{x^4 - 3} \right).$$

[The answer could be simplified to $y' = 2(2x + 1)^4 (x^4 - 3)^5 (29x^4 + 12x^3 - 15)$, but this is unnecessary.]

56. $y = \frac{(x^3 + 1)^4 \sin^2 x}{x^{1/3}} \Rightarrow \ln |y| = 4 \ln |x^3 + 1| + 2 \ln |\sin x| - \frac{1}{3} \ln |x|.$

$$\text{So } \frac{y'}{y} = 4 \frac{3x^2}{x^3 + 1} + 2 \frac{\cos x}{\sin x} - \frac{1}{3x} \Rightarrow y' = \frac{(x^3 + 1)^4 \sin^2 x}{x^{1/3}} \left(\frac{12x^2}{x^3 + 1} + 2 \cot x - \frac{1}{3x} \right).$$

$$57. y = \frac{\sin^2 x \tan^4 x}{(x^2 + 1)^2} \Rightarrow \ln y = \ln(\sin^2 x \tan^4 x) - \ln(x^2 + 1)^2 \Rightarrow$$

$$\ln y = \ln(\sin x)^2 + \ln(\tan x)^4 - \ln(x^2 + 1)^2 \Rightarrow \ln y = 2 \ln |\sin x| + 4 \ln |\tan x| - 2 \ln(x^2 + 1) \Rightarrow$$

$$\frac{1}{y} y' = 2 \cdot \frac{1}{\sin x} \cdot \cos x + 4 \cdot \frac{1}{\tan x} \cdot \sec^2 x - 2 \cdot \frac{1}{x^2 + 1} \cdot 2x \Rightarrow$$

$$y' = \frac{\sin^2 x \tan^4 x}{(x^2 + 1)^2} \left(2 \cot x + \frac{4 \sec^2 x}{\tan x} - \frac{4x}{x^2 + 1} \right)$$

$$58. y = \sqrt[4]{\frac{x^2 + 1}{x^2 - 1}} \Rightarrow \ln y = \frac{1}{4} \ln(x^2 + 1) - \frac{1}{4} \ln(x^2 - 1) \Rightarrow \frac{1}{y} y' = \frac{1}{4} \cdot \frac{1}{x^2 + 1} \cdot 2x - \frac{1}{4} \cdot \frac{1}{x^2 - 1} \cdot 2x \Rightarrow$$

$$y' = \sqrt[4]{\frac{x^2 + 1}{x^2 - 1}} \cdot \frac{1}{2} \left(\frac{x}{x^2 + 1} - \frac{x}{x^2 - 1} \right) = \frac{1}{2} \sqrt[4]{\frac{x^2 + 1}{x^2 - 1}} \left(\frac{-2x}{x^4 - 1} \right) = \frac{x}{1 - x^4} \sqrt[4]{\frac{x^2 + 1}{x^2 - 1}}$$

$$59. \int_2^4 \frac{3}{x} dx = 3 \int_2^4 \frac{1}{x} dx = 3 \left[\ln |x| \right]_2^4 = 3(\ln 4 - \ln 2) = 3 \ln \frac{4}{2} = 3 \ln 2$$

$$60. \int_1^2 \frac{4 + u^2}{u^3} du = \int_1^2 (4u^{-3} + u^{-1}) du = \left[-\frac{4}{2} u^{-2} + \ln |u| \right]_1^2 = \left[\frac{-2}{u^2} + \ln u \right]_1^2$$

$$= \left(-\frac{1}{2} + \ln 2 \right) - (-2 + \ln 1) = \frac{3}{2} + \ln 2$$

$$61. \int_1^2 \frac{dt}{8 - 3t} = \left[-\frac{1}{3} \ln |8 - 3t| \right]_1^2 = -\frac{1}{3} \ln 2 - \left(-\frac{1}{3} \ln 5 \right) = \frac{1}{3} (\ln 5 - \ln 2) = \frac{1}{3} \ln \frac{5}{2}$$

Or: Let $u = 8 - 3t$. Then $du = -3 dt$, so

$$\int_1^2 \frac{dt}{8 - 3t} = \int_5^2 \frac{-\frac{1}{3} du}{u} = \left[-\frac{1}{3} \ln |u| \right]_5^2 = -\frac{1}{3} \ln 2 - \left(-\frac{1}{3} \ln 5 \right) = \frac{1}{3} (\ln 5 - \ln 2) = \frac{1}{3} \ln \frac{5}{2}.$$

$$62. \int_4^9 \left(\sqrt{x} + \frac{1}{\sqrt{x}} \right)^2 dx = \int_4^9 \left(x + 2 + \frac{1}{x} \right) dx = \left[\frac{1}{2} x^2 + 2x + \ln x \right]_4^9 = \frac{81}{2} + 18 + \ln 9 - (8 + 8 + \ln 4)$$

$$= \frac{85}{2} + \ln \frac{9}{4}$$

$$63. \int_1^e \frac{x^2 + x + 1}{x} dx = \int_1^e \left(x + 1 + \frac{1}{x} \right) dx = \left[\frac{1}{2} x^2 + x + \ln x \right]_1^e = \left(\frac{1}{2} e^2 + e + 1 \right) - \left(\frac{1}{2} + 1 + 0 \right)$$

$$= \frac{1}{2} e^2 + e - \frac{1}{2}$$

$$64. \text{ Let } u = \ln x. \text{ Then } du = \frac{1}{x} dx, \text{ so } \int_e^6 \frac{dx}{x \ln x} = \int_1^{\ln 6} \frac{1}{u} du = \left[\ln |u| \right]_1^{\ln 6} = \ln \ln 6 - \ln 1 = \ln \ln 6$$

$$65. \text{ Let } u = 6x - x^3. \text{ Then } du = (6 - 3x^2) dx = 3(2 - x^2) dx, \text{ so}$$

$$\int \frac{2 - x^2}{6x - x^3} dx = \int \frac{\frac{1}{3} du}{u} = \frac{1}{3} \ln |u| + C = \frac{1}{3} \ln |6x - x^3| + C.$$

66. Let $u = 2 + \sin x$. Then $du = \cos x \, dx$, so

$$\int \frac{\cos x}{2 + \sin x} \, dx = \int \frac{1}{u} \, du = \ln |u| + C = \ln |2 + \sin x| + C = \ln(2 + \sin x) + C \quad [\text{since } 2 + \sin x > 0].$$

67. Let $u = \ln x$. Then $du = \frac{dx}{x} \Rightarrow \int \frac{(\ln x)^2}{x} \, dx = \int u^2 \, du = \frac{1}{3}u^3 + C = \frac{1}{3}(\ln x)^3 + C$.

68. Let $u = 1 + \sqrt{x}$. Then $du = \frac{1}{2\sqrt{x}} \, dx$, so $\int \frac{(1 + \sqrt{x})^4}{\sqrt{x}} \, dx = 2 \int u^4 \, du = \frac{2}{5}u^5 + C = \frac{2}{5}(1 + \sqrt{x})^5 + C$.

69. (a) $\frac{d}{dx} (\ln |\sin x| + C) = \frac{1}{\sin x} \cos x = \cot x$

(b) Let $u = \sin x$. Then $du = \cos x \, dx$, so $\int \cot x \, dx = \int \frac{\cos x}{\sin x} \, dx = \int \frac{du}{u} = \ln |u| + C = \ln |\sin x| + C$.

70. Let $u = x - 2$. Then the area is

$$A = - \int_{-4}^{-1} \frac{2}{x-2} \, dx = -2 \int_{-6}^{-3} \frac{du}{u} = [-2 \ln |u|]_{-6}^{-3} = -2 \ln 3 + 2 \ln 6 = 2 \ln 2 \approx 1.386.$$

71. The cross-sectional area is $\pi(1/\sqrt{x+1})^2 = \pi/(x+1)$. Therefore, the volume is

$$\int_0^1 \frac{\pi}{x+1} \, dx = \pi [\ln(x+1)]_0^1 = \pi(\ln 2 - \ln 1) = \pi \ln 2.$$

72. Using cylindrical shells, we get $V = \int_0^3 \frac{2\pi x}{x^2+1} \, dx = \pi [\ln(1+x^2)]_0^3 = \pi \ln 10$.

73. $W = \int_{V_1}^{V_2} P \, dV = \int_{600}^{1000} \frac{C}{V} \, dV = C \int_{600}^{1000} \frac{1}{V} \, dV = C [\ln |V|]_{600}^{1000}$
 $= C(\ln 1000 - \ln 600) = C \ln \frac{1000}{600} = C \ln \frac{5}{3}$

Initially, $PV = C$, where $P = 150$ kPa and $V = 600$ cm³, so $C = (150)(600) = 90,000$. Thus,

$$W = 90,000 \ln \frac{5}{3} \approx 45,974 \text{ kPa} \cdot \text{cm}^3 = 45,974(10^3 \text{ Pa})(10^{-6} \text{ m}^3) = 45,974 \text{ Pa} \cdot \text{m}^3 = 45,974 \text{ N} \cdot \text{m}$$

$$[\text{Pa} = \text{N/m}^2] = 45,974 \text{ J}$$

74. $f''(x) = x^{-2}, x > 0 \Rightarrow f'(x) = -1/x + C \Rightarrow f(x) = -\ln x + Cx + D$. $0 = f(1) = C + D$ and
 $0 = f(2) = -\ln 2 + 2C + D = -\ln 2 + 2C - C = -\ln 2 + C \Rightarrow C = \ln 2$ and $D = -\ln 2$. So
 $f(x) = -\ln x + (\ln 2)x - \ln 2$.

75. $f(x) = 2x + \ln x \Rightarrow f'(x) = 2 + 1/x$. If $g = f^{-1}$, then $f(1) = 2 \Rightarrow g(2) = 1$, so
 $g'(2) = 1/f'(g(2)) = 1/f'(1) = \frac{1}{3}$.

76. (a) Let $f(x) = \ln x \Rightarrow f'(x) = 1/x \Rightarrow f''(x) = -1/x^2$. The linear approximation to $\ln x$ near 1 is $\ln x \approx f(1) + f'(1)(x-1) = \ln 1 + \frac{1}{1}(x-1) = x-1$.

(b)

(c)

From the graph, it appears that the linear approximation is accurate to within 0.1 for x between about 0.62 and 1.51.

77. (a)

We interpret $\ln 1.5$ as the area under the curve $y = 1/x$ from $x = 1$ to $x = 1.5$. The area of the rectangle $BCDE$ is $\frac{1}{2} \cdot \frac{2}{3} = \frac{1}{3}$. The area of the trapezoid $ABCD$ is $\frac{1}{2} \cdot \frac{1}{2} \left(1 + \frac{2}{3}\right) = \frac{5}{12}$. Thus, by comparing areas, we observe that $\frac{1}{3} < \ln 1.5 < \frac{5}{12}$.

(b) With $f(t) = 1/t$, $n = 10$, and $\Delta t = 0.05$, we have

$$\begin{aligned} \ln 1.5 &= \int_1^{1.5} (1/t) dt \approx (0.05)[f(1.025) + f(1.075) + \cdots + f(1.475)] \\ &= (0.05) \left[\frac{1}{1.025} + \frac{1}{1.075} + \cdots + \frac{1}{1.475} \right] \approx 0.4054 \end{aligned}$$

78. (a) $y = \frac{1}{t}$, $y' = -\frac{1}{t^2}$. The slope of AD is $\frac{1/2 - 1}{2 - 1} = -\frac{1}{2}$. Let c be the t -coordinate of the point on $y = \frac{1}{t}$ with

slope $-\frac{1}{2}$. Then $-\frac{1}{c^2} = -\frac{1}{2} \Rightarrow c^2 = 2 \Rightarrow c = \sqrt{2}$ since $c > 0$. Therefore the tangent line is given by

$$y - \frac{1}{\sqrt{2}} = -\frac{1}{2}(t - \sqrt{2}) \Rightarrow y = -\frac{1}{2}t + \sqrt{2}.$$

(b)

Since the graph of $y = 1/t$ is concave upward, the graph lies above the tangent line, that is, above the line segment BC . Now

$|AB| = -\frac{1}{2} + \sqrt{2}$ and $|CD| = -1 + \sqrt{2}$. So the area of the trapezoid $ABCD$ is

$$\frac{1}{2} \left[\left(-\frac{1}{2} + \sqrt{2}\right) + \left(-1 + \sqrt{2}\right) \right] 1 = -\frac{3}{4} + \sqrt{2} \approx 0.6642. \text{ So}$$

$\ln 2 > \text{area of trapezoid } ABCD > 0.66$.

79.

The area of R_i is $\frac{1}{i+1}$ and so $\frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n} < \int_1^n \frac{1}{t} dt = \ln n$.

The area of S_i is $\frac{1}{i}$ and so $1 + \frac{1}{2} + \dots + \frac{1}{n-1} > \int_1^n \frac{1}{t} dt = \ln n$.

80. If $f(x) = \ln(x^r)$, then $f'(x) = (1/x^r)(rx^{r-1}) = r/x$. But if $g(x) = r \ln x$, then $g'(x) = r/x$. So f and g must differ by a constant: $\ln(x^r) = r \ln x + C$. Put $x = 1$: $\ln(1^r) = r \ln 1 + C \Rightarrow C = 0$, so $\ln(x^r) = r \ln x$.

81. The curve and the line will determine a region when they intersect at two or more points. So we solve the equation $x/(x^2 + 1) = mx \Rightarrow$

$$x = 0 \text{ or } mx^2 + m - 1 = 0 \Rightarrow x = 0 \text{ or}$$

$$x = \frac{\pm \sqrt{-4(m)(m-1)}}{2m} = \pm \sqrt{\frac{1}{m} - 1}. \text{ Note that if } m = 1, \text{ this}$$

has only the solution $x = 0$, and no region is determined. But if

$$1/m - 1 > 0 \Leftrightarrow 1/m > 1 \Leftrightarrow 0 < m < 1, \text{ then there are two}$$

solutions. [Another way of seeing this is to observe that the slope of the tangent to $y = x/(x^2 + 1)$ at the origin is $y' = 1$ and therefore we must have $0 < m < 1$.] Note that we cannot just integrate between the positive and negative roots, since the curve and the line cross at the origin. Since mx and $x/(x^2 + 1)$ are both odd functions,

the total area is twice the area between the curves on the interval $[0, \sqrt{1/m - 1}]$. So the total area enclosed is

$$\begin{aligned} 2 \int_0^{\sqrt{1/m-1}} \left[\frac{x}{x^2+1} - mx \right] dx &= 2 \left[\frac{1}{2} \ln(x^2+1) - \frac{1}{2} mx^2 \right]_0^{\sqrt{1/m-1}} \\ &= \left[\ln \left(\frac{1}{m} - 1 + 1 \right) - m \left(\frac{1}{m} - 1 \right) \right] - (\ln 1 - 0) \\ &= \ln \left(\frac{1}{m} \right) + m - 1 = m - \ln m - 1 \end{aligned}$$

$$82. \lim_{x \rightarrow \infty} [\ln(2+x) - \ln(1+x)] = \lim_{x \rightarrow \infty} \ln \left(\frac{2+x}{1+x} \right) = \lim_{x \rightarrow \infty} \ln \left(\frac{2/x+1}{1/x+1} \right) = \ln \frac{1}{1} = \ln 1 = 0$$

83. If $f(x) = \ln(1+x)$, then $f'(x) = \frac{1}{1+x}$, so $f'(0) = 1$.

$$\text{Thus, } \lim_{x \rightarrow 0} \frac{\ln(1+x)}{x} = \lim_{x \rightarrow 0} \frac{f(x)}{x} = \lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x - 0} = f'(0) = 1.$$

From the graphs, we see that $f(x) = x^{0.1} > g(x) = \ln x$ for approximately $0 < x < 3.06$, and then $g(x) > f(x)$ for $3.06 < x < 3.43 \times 10^{15}$ (approximately). At that point, the graph of f finally surpasses the graph of g for good.

(c) From the graph at left, it seems that $\frac{\ln x}{x^{0.1}} < 0.1$ whenever $x > 1.3 \times 10^{28}$ (approximately). So we can take $N = 1.3 \times 10^{28}$, or any larger number.

7.3* The Natural Exponential Function

1. (a) e is the number such that $\ln e = 1$. (c)
(b) $e \approx 2.71828$

The function value at $x = 0$ is 1 and the slope at $x = 0$ is 1.

2. (a) $e^{\ln 6} = 6$ (b) $\ln \sqrt{e} = \ln(e^{1/2}) = \frac{1}{2}$
3. (a) $\ln e^{\sqrt{2}} = \sqrt{2}$ (b) $e^{3 \ln 2} = (e^{\ln 2})^3 = 2^3 = 8$
4. (a) $\ln e^{\sin x} = \sin x$ (b) $e^{x + \ln x} = e^x e^{\ln x} = x e^x$
5. (a) $2 \ln x = 1 \Rightarrow \ln x = \frac{1}{2} \Rightarrow x = e^{1/2} = \sqrt{e}$
(b) $e^{-x} = 5 \Rightarrow -x = \ln 5 \Rightarrow x = -\ln 5$

$$6. (a) e^{2x+3} - 7 = 0 \Rightarrow e^{2x+3} = 7 \Rightarrow 2x + 3 = \ln 7 \Rightarrow 2x = \ln 7 - 3 \Rightarrow x = \frac{1}{2}(\ln 7 - 3)$$

$$(b) \ln(5 - 2x) = -3 \Rightarrow 5 - 2x = e^{-3} \Rightarrow 2x = 5 - e^{-3} \Rightarrow x = \frac{1}{2}(5 - e^{-3})$$

$$7. \ln(\ln x) = 1 \Leftrightarrow e^{\ln(\ln x)} = e^1 \Leftrightarrow \ln x = e^1 = e \Leftrightarrow e^{\ln x} = e^e \Leftrightarrow x = e^e$$

$$8. e^{e^x} = 10 \Leftrightarrow \ln(e^{e^x}) = \ln 10 \Leftrightarrow e^x \ln e = e^x = \ln 10 \Leftrightarrow \ln e^x = \ln(\ln 10) \Leftrightarrow x = \ln(\ln 10)$$

$$9. 2 \ln x = \ln 2 + \ln(3x - 4) \Rightarrow \ln x^2 = \ln[2(3x - 4)] \Rightarrow \ln x^2 = \ln(6x - 8) \Rightarrow x^2 = 6x - 8 \Rightarrow x^2 - 6x + 8 = 0 \Rightarrow (x - 2)(x - 4) = 0 \Rightarrow x = 2 \text{ or } x = 4, \text{ both are valid solutions.}$$

$$10. \ln(2x + 1) = 2 - \ln x \Rightarrow \ln x + \ln(2x + 1) = \ln e^2 \Rightarrow \ln[x(2x + 1)] = \ln e^2 \Rightarrow 2x^2 + x = e^2 \Rightarrow 2x^2 + x - e^2 = 0 \Rightarrow x = \frac{-1 + \sqrt{1 + 8e^2}}{4} \quad \{\text{since } x > 0\}.$$

$$11. e^{ax} = Ce^{bx} \Leftrightarrow \ln e^{ax} = \ln[C(e^{bx})] \Leftrightarrow ax = \ln C + bx + \ln e^{bx} \Leftrightarrow ax = \ln C + bx \Leftrightarrow ax - bx = \ln C \Leftrightarrow (a - b)x = \ln C \Leftrightarrow x = \frac{\ln C}{a - b}$$

$$12. 7e^x - e^{2x} = 12 \Leftrightarrow (e^x)^2 - 7e^x + 12 = 0 \Leftrightarrow (e^x - 3)(e^x - 4) = 0, \text{ so we have either } e^x = 3 \Leftrightarrow x = \ln 3, \text{ or } e^x = 4 \Leftrightarrow x = \ln 4.$$

$$13. e^{2+5x} = 100 \Rightarrow \ln(e^{2+5x}) = \ln 100 \Rightarrow 2 + 5x = \ln 100 \Rightarrow 5x = \ln 100 - 2 \Rightarrow x = \frac{1}{5}(\ln 100 - 2) \approx 0.5210$$

$$14. \ln(1 + \sqrt{x}) = 2 \Rightarrow 1 + \sqrt{x} = e^2 \Rightarrow \sqrt{x} = e^2 - 1 \Rightarrow x = (e^2 - 1)^2 \approx 40.8200$$

$$15. \ln(e^x - 2) = 3 \Rightarrow e^x - 2 = e^3 \Rightarrow e^x = e^3 + 2 \Rightarrow x = \ln(e^3 + 2) \approx 3.0949$$

$$16. e^{1/(x-4)} = 7 \Rightarrow \ln e^{1/(x-4)} = \ln 7 \Rightarrow \frac{1}{x-4} = \ln 7 \Rightarrow \frac{1}{\ln 7} = x - 4 \Rightarrow x = 4 + \frac{1}{\ln 7} \approx 4.5139$$

$$17. (a) e^x < 10 \Rightarrow \ln e^x < \ln 10 \Rightarrow x < \ln 10 \Rightarrow x \in (-\infty, \ln 10)$$

$$(b) \ln x > -1 \Rightarrow e^{\ln x} > e^{-1} \Rightarrow x > e^{-1} \Rightarrow x \in (1/e, \infty)$$

$$18. (a) 2 < \ln x < 9 \Rightarrow e^2 < e^{\ln x} < e^9 \Rightarrow e^2 < x < e^9 \Rightarrow x \in (e^2, e^9)$$

$$(b) e^{2-3x} > 4 \Rightarrow \ln e^{2-3x} > \ln 4 \Rightarrow 2 - 3x > \ln 4 \Rightarrow -3x > \ln 4 - 2 \Rightarrow x < -\frac{1}{3}(\ln 4 - 2) \Rightarrow x \in (-\infty, \frac{1}{3}(2 - \ln 4))$$

19.

20. We start with the graph of $y = e^x$ (Figure 2), vertically stretch by a factor of 2, and then shift 1 unit upward. There is a horizontal asymptote of $y = 1$.

21. We start with the graph of $y = e^x$ (Figure 2), reflect it about the x -axis, and then shift 3 units upward. Note the horizontal asymptote of $y = 3$.

22. We start with the graph of $y = e^x$ (Figure 2), reflect it about the y -axis, and then about the x -axis (or just rotate 180° to handle both reflections) to obtain the graph of $y = -e^{-x}$. Now shift this graph 1 unit upward, vertically stretch by a factor of 5, and then shift 2 units upward.

23. (a) To find the equation of the graph that results from shifting the graph of $y = e^x$ 2 units downward, we subtract 2 from the original function to get $y = e^x - 2$.
- (b) To find the equation of the graph that results from shifting the graph of $y = e^x$ 2 units to the right, we replace x with $x - 2$ in the original function to get $y = e^{(x-2)}$.
- (c) To find the equation of the graph that results from reflecting the graph of $y = e^x$ about the x -axis, we multiply the original function by -1 to get $y = -e^x$.
- (d) To find the equation of the graph that results from reflecting the graph of $y = e^x$ about the y -axis, we replace x with $-x$ in the original function to get $y = e^{-x}$.
- (e) To find the equation of the graph that results from reflecting the graph of $y = e^x$ about the x -axis and then about the y -axis, we first multiply the original function by -1 (to get $y = -e^x$) and then replace x with $-x$ in this equation to get $y = -e^{-x}$.
24. (a) This reflection consists of first reflecting the graph about the x -axis (giving the graph with equation $y = -e^x$) and then shifting this graph $2 \cdot 4 = 8$ units upward. So the equation is $y = -e^x + 8$.
- (b) This reflection consists of first reflecting the graph about the y -axis (giving the graph with equation $y = e^{-x}$) and then shifting this graph $2 \cdot 2 = 4$ units to the right. So the equation is $y = e^{-(x-4)}$.

$$25. \lim_{x \rightarrow \infty} e^{1-x^3} = \lim_{x \rightarrow \infty} (e^1 \cdot e^{-x^3}) = e \lim_{x \rightarrow \infty} \frac{1}{e^{x^3}} = e \cdot 0 = 0$$

26. If we let $t = \tan x$, then as $x \rightarrow (\pi/2)^+$, $t \rightarrow -\infty$. Thus, $\lim_{x \rightarrow (\pi/2)^+} e^{\tan x} = \lim_{t \rightarrow -\infty} e^t = 0$.
27. Divide numerator and denominator by e^{3x} : $\lim_{x \rightarrow \infty} \frac{e^{3x} - e^{-3x}}{e^{3x} + e^{-3x}} = \lim_{x \rightarrow \infty} \frac{1 - e^{-6x}}{1 + e^{-6x}} = \frac{1 - 0}{1 + 0} = 1$
28. Divide numerator and denominator by e^{-3x} : $\lim_{x \rightarrow -\infty} \frac{e^{3x} - e^{-3x}}{e^{3x} + e^{-3x}} = \lim_{x \rightarrow -\infty} \frac{e^{6x} - 1}{e^{6x} + 1} = \frac{0 - 1}{0 + 1} = -1$
29. Let $t = 3/(2 - x)$. As $x \rightarrow 2^+$, $t \rightarrow -\infty$. So $\lim_{x \rightarrow 2^+} e^{3/(2-x)} = \lim_{t \rightarrow -\infty} e^t = 0$ by (6).
30. Let $t = 3/(2 - x)$. As $x \rightarrow 2^-$, $t \rightarrow \infty$. So $\lim_{x \rightarrow 2^-} e^{3/(2-x)} = \lim_{t \rightarrow \infty} e^t = \infty$ by (6).
31. By the Product Rule, $f(x) = x^2 e^x \Rightarrow f'(x) = x^2 \frac{d}{dx}(e^x) + e^x \frac{d}{dx}(x^2) = x^2 e^x + e^x(2x) = x e^x(x + 2)$.
32. By the Quotient Rule, $y = \frac{e^x}{1+x} \Rightarrow y' = \frac{(1+x)e^x - e^x(1)}{(1+x)^2} = \frac{e^x + x e^x - e^x}{(x+1)^2} = \frac{x e^x}{(x+1)^2}$.
33. By (9), $y = e^{ax^3} \Rightarrow y' = e^{ax^3} \frac{d}{dx}(ax^3) = 3ax^2 e^{ax^3}$.
34. $y = e^u(\cos u + cu) \Rightarrow y' = e^u(-\sin u + c) + (\cos u + cu)e^u = e^u(\cos u - \sin u + cu + c)$
35. $f(u) = e^{1/u} \Rightarrow f'(u) = e^{1/u} \cdot \frac{d}{du}\left(\frac{1}{u}\right) = e^{1/u}\left(\frac{-1}{u^2}\right) = \left(\frac{-1}{u^2}\right)e^{1/u}$
36. $y = e^x \ln x \Rightarrow y' = e^x\left(\frac{1}{x}\right) + (\ln x)(e^x) = e^x\left(\ln x + \frac{1}{x}\right)$
37. By (9), $F(t) = e^{t \sin 2t} \Rightarrow$
 $F'(t) = e^{t \sin 2t}(t \sin 2t)' = e^{t \sin 2t}(t \cdot 2 \cos 2t + \sin 2t \cdot 1) = e^{t \sin 2t}(2t \cos 2t + \sin 2t)$
38. $y = e^{k \tan \sqrt{x}} \Rightarrow y' = e^{k \tan \sqrt{x}} \cdot \frac{d}{dx}(k \tan \sqrt{x}) = e^{k \tan \sqrt{x}}\left(k \sec^2 \sqrt{x} \cdot \frac{1}{2}x^{-1/2}\right) = \frac{k \sec^2 \sqrt{x}}{2\sqrt{x}} e^{k \tan \sqrt{x}}$
39. $y = \sqrt{1 + 2e^{3x}} \Rightarrow y' = \frac{1}{2}(1 + 2e^{3x})^{-1/2} \frac{d}{dx}(1 + 2e^{3x}) = \frac{1}{2\sqrt{1 + 2e^{3x}}}(2e^{3x} \cdot 3) = \frac{3e^{3x}}{\sqrt{1 + 2e^{3x}}}$
40. $y = \cos(e^{\pi x}) \Rightarrow y' = -\sin(e^{\pi x}) \cdot e^{\pi x} \cdot \pi = -\pi e^{\pi x} \sin(e^{\pi x})$
41. $y = e^{e^x} \Rightarrow y' = e^{e^x} \cdot \frac{d}{dx}(e^x) = e^{e^x} \cdot e^x$ or e^{e^x+x}
42. $y = \sqrt{1 + x e^{-2x}} \Rightarrow y' = \frac{1}{2}(1 + x e^{-2x})^{-1/2} [x(-2e^{-2x}) + e^{-2x}] = \frac{e^{-2x}(-2x + 1)}{2\sqrt{1 + x e^{-2x}}}$
43. By the Quotient Rule, $y = \frac{ae^x + b}{ce^x + d} \Rightarrow$
 $y' = \frac{(ce^x + d)(ae^x) - (ae^x + b)(ce^x)}{(ce^x + d)^2} = \frac{(ace^x + ad - ace^x - bc)e^x}{(ce^x + d)^2} = \frac{(ad - bc)e^x}{(ce^x + d)^2}$
44. $y = \frac{e^x + e^{-x}}{e^x - e^{-x}} \Rightarrow y' = \frac{(e^x - e^{-x})(e^x - e^{-x}) - (e^x + e^{-x})(e^x + e^{-x})}{(e^x - e^{-x})^2}$
 $= \frac{(e^{2x} - 2 + e^{-2x}) - (e^{2x} + 2 + e^{-2x})}{(e^x - e^{-x})^2} = -\frac{4}{(e^x - e^{-x})^2}$

45. $y = e^{2x} \cos \pi x \Rightarrow y' = e^{2x}(-\pi \sin \pi x) + (\cos \pi x)(2e^{2x}) = e^{2x}(2 \cos \pi x - \pi \sin \pi x).$

At $(0, 1)$, $y' = 1(2 - 0) = 2$, so an equation of the tangent line is $y - 1 = 2(x - 0)$, or $y = 2x + 1$.

46. $y = \frac{e^x}{x} \Rightarrow y' = \frac{x \cdot e^x - e^x \cdot 1}{x^2} = \frac{e^x(x-1)}{x^2}.$ At $(1, e)$, $y' = 0$, and an equation of the tangent line is $y - e = 0(x - 1)$, or $y = e$.

47. $\frac{d}{dx}(e^{x^2y}) = \frac{d}{dx}(x + y) \Rightarrow e^{x^2y}(x^2y' + y \cdot 2x) = 1 + y' \Rightarrow x^2e^{x^2y}y' + 2xye^{x^2y} = 1 + y' \Rightarrow$
 $x^2e^{x^2y}y' - y' = 1 - 2xye^{x^2y} \Rightarrow y'(x^2e^{x^2y} - 1) = 1 - 2xye^{x^2y} \Rightarrow y' = \frac{1 - 2xye^{x^2y}}{x^2e^{x^2y} - 1}$

48. $y = Ae^{-x} + Bxe^{-x} \Rightarrow y' = -Ae^{-x} + Be^{-x} - Bxe^{-x} = (B - A)e^{-x} - Bxe^{-x} \Rightarrow$
 $y'' = (A - B)e^{-x} - Be^{-x} + Bxe^{-x} = (A - 2B)e^{-x} + Bxe^{-x}$, so
 $y'' + 2y' + y = (A - 2B)e^{-x} + Bxe^{-x} + 2[(B - A)e^{-x} - Bxe^{-x}] + Ae^{-x} + Bxe^{-x} = 0.$

49. $y = e^{rx} \Rightarrow y' = re^{rx} \Rightarrow y'' = r^2e^{rx}$, so if $y = e^{rx}$ satisfies the differential equation $y'' + 6y' + 8y = 0$, then $r^2e^{rx} + 6re^{rx} + 8e^{rx} = 0$; that is, $e^{rx}(r^2 + 6r + 8) = 0$. Since $e^{rx} > 0$ for all x , we must have $r^2 + 6r + 8 = 0$, or $(r + 2)(r + 4) = 0$, so $r = -2$ or -4 .

50. $y = e^{\lambda x} \Rightarrow y' = \lambda e^{\lambda x} \Rightarrow y'' = \lambda^2 e^{\lambda x}$. Thus, $y + y' = y'' \Leftrightarrow e^{\lambda x} + \lambda e^{\lambda x} = \lambda^2 e^{\lambda x} \Leftrightarrow$
 $e^{\lambda x}(\lambda^2 - \lambda - 1) = 0 \Leftrightarrow \lambda = \frac{1 \pm \sqrt{5}}{2}$, since $e^{\lambda x} \neq 0$.

51. $f(x) = e^{2x} \Rightarrow f'(x) = 2e^{2x} \Rightarrow f''(x) = 2 \cdot 2e^{2x} = 2^2e^{2x} \Rightarrow$
 $f'''(x) = 2^2 \cdot 2e^{2x} = 2^3e^{2x} \Rightarrow \dots \Rightarrow f^{(n)}(x) = 2^n e^{2x}$

52. $f(x) = xe^{-x} \Rightarrow f'(x) = x(-e^{-x}) + e^{-x} = (1 - x)e^{-x} \Rightarrow$
 $f''(x) = (1 - x)(-e^{-x}) + e^{-x}(-1) = (x - 2)e^{-x} \Rightarrow f'''(x) = (x - 2)(-e^{-x}) + e^{-x} = (3 - x)e^{-x} \Rightarrow$
 $f^{(4)}(x) = (3 - x)(-e^{-x}) + e^{-x}(-1) = (x - 4)e^{-x} \Rightarrow \dots \Rightarrow f^{(n)}(x) = (-1)^n(x - n)e^{-x}.$
 So $D^{1000}xe^{-x} = (x - 1000)e^{-x}.$

53. (a) $f(x) = e^x + x$ is continuous on $\mathbb{R}$ and $f(-1) = e^{-1} - 1 < 0 < 1 = f(0)$, so by the Intermediate Value Theorem, $e^x + x = 0$ has a root in $(-1, 0)$.

(b) $f(x) = e^x + x \Rightarrow f'(x) = e^x + 1$, so $x_{n+1} = x_n - \frac{e^{x_n} + x_n}{e^{x_n} + 1}$. Using $x_1 = -0.5$, we get
 $x_2 \approx -0.566311$, $x_3 \approx -0.567143 \approx x_4$, so the root is -0.567143 to six decimal places.

54.

From the graph, it appears that the curves intersect at about $x \approx 1.2$ or 1.3 .

We use Newton's Method with $f(x) = x^3 + x - 3 - e^{-x^2}$, so

$$f'(x) = 3x^2 + 1 + 2xe^{-x^2}, \text{ and the formula is}$$

$x_{n+1} = x_n - f(x_n)/f'(x_n)$. We take $x_1 = 1.2$, and the formula gives
 $x_2 \approx 1.252462$, $x_3 \approx 1.251045$, and $x_4 \approx x_5 \approx 1.251044$. So the root
 of the equation, correct to six decimal places, is $x = 1.251044$.

55. (a) $m(t) = 24 \cdot e^{-(\ln 2)t/25} = 24 \cdot 2^{-t/25} \Rightarrow m(40) = 24 \cdot 2^{-40/25} \approx 7.92$ mg.

(b) $m'(t) = 24 \frac{d}{dt} \left[e^{-(\ln 2)t/25} \right] = 24 \cdot e^{-(\ln 2)t/25} \left(-\frac{\ln 2}{25} \right)$, so

$m'(40) = 24e^{-(\ln 2)(40)/25} \left(-\frac{\ln 2}{25} \right) \approx -0.22$ mg/yr

(c) $m(t) = 5 \Rightarrow 24e^{-(\ln 2)t/25} = 5 \Rightarrow e^{-(\ln 2)t/25} = \frac{5}{24} \Rightarrow -(\ln 2)t/25 = \ln \frac{5}{24} \Rightarrow$

$t = -25 \frac{\ln \frac{5}{24}}{\ln 2} \approx 56.6$ yr

From the graph, we estimate that the most rapid increase in the percentage of households in the United States with at least one VCR occurs at about $t = 8$. To maximize the first derivative, we need to determine the values for which the second derivative is 0. We'll use

$V(t) = \frac{a}{1 + be^{ct}}$, and substitute $a = 85$, $b = 53$, and $c = -0.5$ later.

$V'(t) = -\frac{a(bce^{ct})}{(1 + be^{ct})^2}$ [by the Reciprocal Rule] and

$$V''(t) = -abc \cdot \frac{(1 + be^{ct})^2 \cdot ce^{ct} - e^{ct} \cdot 2(1 + be^{ct}) \cdot bce^{ct}}{[(1 + be^{ct})^2]^2}$$

$$= \frac{-abc \cdot ce^{ct}(1 + be^{ct})[(1 + be^{ct}) - 2be^{ct}]}{(1 + be^{ct})^4} = \frac{-abc^2 e^{ct}(1 - be^{ct})}{(1 + be^{ct})^3}$$

So $V''(t) = 0 \Leftrightarrow 1 = be^{ct} \Leftrightarrow e^{ct} = 1/b$. Now graph $y = e^{-0.5t}$ and $y = \frac{1}{53}$. These graphs intersect at $t \approx 7.94$ years, which corresponds to roughly midyear 1988. [Alternatively, we could use the rootfinder on a calculator to solve $e^{-0.5t} = \frac{1}{53}$. Or, if you have already studied logarithms, you can solve $e^{ct} = 1/b$ as follows:

$$ct = \ln(1/b) \Leftrightarrow t = (1/c) \ln(1/b) = -2 \ln \frac{1}{53} \approx 7.94 \text{ years.}$$

57. (a) $\lim_{t \rightarrow \infty} p(t) = \lim_{t \rightarrow \infty} \frac{1}{1 + ae^{-kt}} = \frac{1}{1 + a \cdot 0} = 1$, since $k > 0 \Rightarrow -kt \rightarrow -\infty \Rightarrow e^{-kt} \rightarrow 0$.

(b) $p(t) = (1 + ae^{-kt})^{-1} \Rightarrow \frac{dp}{dt} = -(1 + ae^{-kt})^{-2} (-kae^{-kt}) = \frac{kae^{-kt}}{(1 + ae^{-kt})^2}$

From the graph of $p(t) = (1 + 10e^{-0.5t})^{-1}$, it seems that $p(t) = 0.8$ (indicating that 80% of the population has heard the rumor) when $t \approx 7.4$ hours.

58. (a)

The displacement function is squeezed between the other two functions. This is because $-1 \leq \sin 4t \leq 1 \Rightarrow$
 $-8e^{-t/2} \leq 8e^{-t/2} \sin 4t \leq 8e^{-t/2}.$

(b) The maximum value of the displacement is about 6.6 cm, occurring at $t \approx 0.36$ s. It occurs just before the graph of the displacement function touches the graph of $8e^{-t/2}$ (when $t = \frac{\pi}{8} \approx 0.39$).

(c) The velocity of the object is the derivative of its displacement function, that is,

$$\frac{d}{dt} (8e^{-t/2} \sin 4t) = 8 \left[e^{-t/2} \cos 4t(4) + \sin 4t \left(-\frac{1}{2}\right) e^{-t/2} \right].$$

If the displacement is zero, then we must have $\sin 4t = 0$ (since the exponential term in the displacement function is always positive). The first time that $\sin 4t = 0$ after $t = 0$ occurs at $t = \frac{\pi}{4}$. Substituting this into our expression for the velocity, and noting that the second term vanishes, we

$$\text{get } v\left(\frac{\pi}{4}\right) = 8e^{-\pi/8} \cos\left(4 \cdot \frac{\pi}{4}\right) \cdot 4 = -32e^{-\pi/8} \approx -21.6 \text{ cm/s.}$$

(d)

The graph indicates that the displacement is less than 2 cm from equilibrium whenever t is larger than about 2.8.

59. $f(x) = x - e^x \Rightarrow f'(x) = 1 - e^x = 0 \Leftrightarrow e^x = 1 \Leftrightarrow x = 0$. Now $f'(x) > 0$ for all $x < 0$ and $f'(x) < 0$ for all $x > 0$, so the absolute maximum value is $f(0) = 0 - 1 = -1$.

60. $g(x) = \frac{e^x}{x} \Rightarrow g'(x) = \frac{xe^x - e^x}{x^2} = 0 \Leftrightarrow e^x(x - 1) = 0 \Rightarrow x = 1$. Now $g'(x) > 0 \Leftrightarrow \frac{xe^x - e^x}{x^2} > 0 \Leftrightarrow x - 1 > 0 \Leftrightarrow x > 1$ and $g'(x) < 0 \Leftrightarrow \frac{xe^x - e^x}{x^2} < 0 \Leftrightarrow x - 1 < 0 \Leftrightarrow x < 1$. Thus there is an absolute minimum value of $g(1) = e$ at $x = 1$.

61. $y = xe^{3x} \Rightarrow y' = xe^{3x} \cdot 3 + e^{3x} \cdot 1 = (3x + 1)e^{3x} \Rightarrow y'' = (3x + 1)e^{3x} \cdot 3 + e^{3x} \cdot 3 = (9x + 6)e^{3x}$. The curve is concave upward at $x \Leftrightarrow y'' > 0$ at $x \Leftrightarrow 9x + 6 > 0 \Leftrightarrow x > -\frac{2}{3}$. Thus, the curve is concave upward on $(-\frac{2}{3}, \infty)$.

62. $f(x) = x^2e^{-x} \Rightarrow f'(x) = x^2(-e^{-x}) + e^{-x} \cdot 2x = (2x - x^2)e^{-x}$, so $f'(x) > 0 \Leftrightarrow 2x - x^2 > 0 \Leftrightarrow x(2 - x) > 0 \Leftrightarrow 0 < x < 2$, so f is increasing on $(0, 2)$.

63. $y = f(x) = e^{-1/(x+1)}$ A. $D = \{x \mid x \neq -1\} = (-\infty, -1) \cup (-1, \infty)$ B. No x -intercept;

y -intercept $= f(0) = e^{-1}$ C. No symmetry D. $\lim_{x \rightarrow \pm\infty} e^{-1/(x+1)} = 1$ since $-1/(x+1) \rightarrow 0$, so $y = 1$ is

a HA. $\lim_{x \rightarrow -1^+} e^{-1/(x+1)} = 0$ since $-1/(x+1) \rightarrow -\infty$, $\lim_{x \rightarrow -1^-} e^{-1/(x+1)} = \infty$ since $-1/(x+1) \rightarrow \infty$, so

$x = -1$ is a VA. E. $f'(x) = e^{-1/(x+1)} / (x+1)^2 \Rightarrow f'(x) > 0$ for all x except $x = -1$, so

f is increasing on $(-\infty, -1)$ and $(-1, \infty)$. F. No extreme values H.

$$G. f''(x) = \frac{e^{-1/(x+1)}}{(x+1)^4} + \frac{e^{-1/(x+1)}(-2)}{(x+1)^3} = -\frac{e^{-1/(x+1)}(2x+1)}{(x+1)^4}$$

$$\Rightarrow f''(x) > 0 \Leftrightarrow 2x+1 < 0 \Leftrightarrow x < -\frac{1}{2}, \text{ so } f \text{ is CU on}$$

$(-\infty, -1)$ and $(-1, -\frac{1}{2})$, and CD on $(-\frac{1}{2}, \infty)$. f has an IP

at $(-\frac{1}{2}, e^{-2})$.

64. $y = f(x) = e^{2x} - e^x$ A. $D = \mathbb{R}$ B. y -intercept: $f(0) = 0$;

x -intercepts: $f(x) = 0 \Rightarrow e^{2x} = e^x \Rightarrow e^x = 1 \Rightarrow x = 0$.

C. No symmetry D. $\lim_{x \rightarrow -\infty} e^{2x} - e^x = 0$, so $y = 0$ is a HA. No VA.

E. $f'(x) = 2e^{2x} - e^x = e^x(2e^x - 1)$, so $f'(x) > 0 \Leftrightarrow e^x > \frac{1}{2} \Leftrightarrow$

$x > \ln \frac{1}{2} = -\ln 2$ and $f'(x) < 0 \Leftrightarrow e^x < \frac{1}{2} \Leftrightarrow x < \ln \frac{1}{2}$, so f is

decreasing on $(-\infty, \ln \frac{1}{2})$ and increasing on $(\ln \frac{1}{2}, \infty)$. F. Local

minimum value $f(\ln \frac{1}{2}) = e^{2 \ln(1/2)} - e^{\ln(1/2)} = (\frac{1}{2})^2 - \frac{1}{2} = -\frac{1}{4}$

G. $f''(x) = 4e^{2x} - e^x = e^x(4e^x - 1)$, so $f''(x) > 0 \Leftrightarrow$

$e^x > \frac{1}{4} \Leftrightarrow x > \ln \frac{1}{4}$ and $f''(x) < 0 \Leftrightarrow x < \ln \frac{1}{4}$.

Thus, f is CD on $(-\infty, \ln \frac{1}{4})$ and CU on $(\ln \frac{1}{4}, \infty)$. f has an IP at $(\ln \frac{1}{4}, (\frac{1}{4})^2 - \frac{1}{4}) = (\ln \frac{1}{4}, -\frac{3}{16})$.

65. $y = f(x) = e^{3x} + e^{-2x}$ A. $D = \mathbb{R}$ B. y -intercept $= f(0) = 2$;

no x -intercept C. No symmetry D. No asymptotes

E. $f'(x) = 3e^{3x} - 2e^{-2x}$, so $f'(x) > 0 \Leftrightarrow 3e^{3x} > 2e^{-2x}$

[multiply by e^{2x}] $\Leftrightarrow e^{5x} > \frac{2}{3} \Leftrightarrow 5x > \ln \frac{2}{3} \Leftrightarrow$

$x > \frac{1}{5} \ln \frac{2}{3} \approx -0.081$. Similarly, $f'(x) < 0 \Leftrightarrow x < \frac{1}{5} \ln \frac{2}{3}$.

f is decreasing on $(-\infty, \frac{1}{5} \ln \frac{2}{3})$ and increasing on $(\frac{1}{5} \ln \frac{2}{3}, \infty)$.

F. Local minimum value $f(\frac{1}{5} \ln \frac{2}{3}) = (\frac{2}{3})^{3/5} + (\frac{2}{3})^{-2/5} \approx 1.96$; no local maximum.

G. $f''(x) = 9e^{3x} + 4e^{-2x}$, so $f''(x) > 0$ for all x , and f is CU on $(-\infty, \infty)$. No IP

66. The function $f(x) = e^{\cos x}$ is periodic with period 2π , so we consider it only on the interval $[0, 2\pi]$. We see that it has local maxima of about $f(0) \approx 2.72$ and $f(2\pi) \approx 2.72$, and a local minimum of about $f(3.14) \approx 0.37$. To find the exact

values, we calculate $f'(x) = -\sin x e^{\cos x}$. This is 0 when $-\sin x = 0 \Leftrightarrow x = 0, \pi$ or 2π (since we are only considering $x \in [0, 2\pi]$). Also $f'(x) > 0 \Leftrightarrow \sin x < 0 \Leftrightarrow 0 < x < \pi$. So $f(0) = f(2\pi) = e$ (both maxima) and $f(\pi) = e^{\cos \pi} = 1/e$ (minimum). To find the inflection points, we calculate and graph

$f''(x) = \frac{d}{dx}(-\sin x e^{\cos x}) = -\cos x e^{\cos x} - \sin x(e^{\cos x})(-\sin x) = e^{\cos x}(\sin^2 x - \cos x)$. From the graph of $f''(x)$, we see that f has inflection points at $x \approx 0.90$ and at $x \approx 5.38$. These x -coordinates correspond to inflection points $(0.90, 1.86)$ and $(5.38, 1.86)$.

67. $f(x) = e^{x^3-x} \rightarrow 0$ as $x \rightarrow -\infty$, and $f(x) \rightarrow \infty$ as $x \rightarrow \infty$. From the graph, it appears that f has a local minimum of about $f(0.58) = 0.68$, and a local maximum of about $f(-0.58) = 1.47$.

To find the exact values, we calculate

$f'(x) = (3x^2 - 1)e^{x^3-x}$, which is 0 when $3x^2 - 1 = 0 \Leftrightarrow x = \pm \frac{1}{\sqrt{3}}$. The negative root corresponds to the local maximum $f\left(-\frac{1}{\sqrt{3}}\right) = e^{(-1/\sqrt{3})^3 - (-1/\sqrt{3})} = e^{2\sqrt{3}/9}$, and the positive root corresponds to the local minimum $f\left(\frac{1}{\sqrt{3}}\right) = e^{(1/\sqrt{3})^3 - (1/\sqrt{3})} = e^{-2\sqrt{3}/9}$. To estimate the inflection points, we calculate and graph

$$f''(x) = \frac{d}{dx}[(3x^2 - 1)e^{x^3-x}] = (3x^2 - 1)e^{x^3-x}(3x^2 - 1) + e^{x^3-x}(6x) = e^{x^3-x}(9x^4 - 6x^2 + 6x + 1).$$

From the graph, it appears that $f''(x)$ changes sign (and thus f has inflection points) at $x \approx -0.15$ and $x \approx -1.09$. From the graph of f , we see that these x -values correspond to inflection points at about $(-0.15, 1.15)$ and $(-1.09, 0.82)$.

68. (a) As $|x| \rightarrow \infty$, $t = -x^2/(2\sigma^2) \rightarrow -\infty$, and $e^t \rightarrow 0$. The HA is $y = 0$. Since t takes on its maximum value at $x = 0$, so does e^t . Showing this result using derivatives, we have $f(x) = e^{-x^2/(2\sigma^2)} \Rightarrow$

$$f'(x) = e^{-x^2/(2\sigma^2)}(-x/\sigma^2). \quad f'(x) = 0 \Leftrightarrow x = 0. \quad \text{Because } f' \text{ changes from positive to negative at } x = 0,$$

$f(0) = 1$ is a local maximum. For inflection points, we find

$$f''(x) = -\frac{1}{\sigma^2} \left[e^{-x^2/(2\sigma^2)} \cdot 1 + x e^{-x^2/(2\sigma^2)} (-x/\sigma^2) \right] = \frac{-1}{\sigma^2} e^{-x^2/(2\sigma^2)} (1 - x^2/\sigma^2).$$

$f''(x) = 0 \Leftrightarrow x^2 = \sigma^2 \Leftrightarrow x = \pm\sigma$. $f''(x) < 0 \Leftrightarrow x^2 < \sigma^2 \Leftrightarrow -\sigma < x < \sigma$. So f is CD on $(-\sigma, \sigma)$ and CU on $(-\infty, -\sigma)$ and (σ, ∞) . IP at $(\pm\sigma, e^{-1/2})$.

(b) Since we have IP at $x = \pm\sigma$, the inflection points move away from the y -axis as σ increases.

(c)

From the graph, we see that as σ increases, the graph tends to spread out and there is more area between the curve and the x -axis.

69. Let $u = -3x$. Then $du = -3 dx$, so

$$\int_0^5 e^{-3x} dx = -\frac{1}{3} \int_0^{-15} e^u du = -\frac{1}{3} [e^u]_0^{-15} = -\frac{1}{3} (e^{-15} - e^0) = \frac{1}{3} (1 - e^{-15}).$$

70. Let $u = -x^2$, so $du = -2x dx$. When $x = 0$, $u = 0$; when $x = 1$, $u = -1$. Thus,

$$\int_0^1 x e^{-x^2} dx = \int_0^{-1} e^u (-\frac{1}{2} du) = -\frac{1}{2} [e^u]_0^{-1} = -\frac{1}{2} (e^{-1} - e^0) = \frac{1}{2} (1 - 1/e).$$

71. Let $u = 1 + e^x$. Then $du = e^x dx$, so $\int e^x \sqrt{1 + e^x} dx = \int \sqrt{u} du = \frac{2}{3} u^{3/2} + C = \frac{2}{3} (1 + e^x)^{3/2} + C$.

72. Let $u = \tan x$. Then $du = \sec^2 x dx$, so $\int \sec^2 x e^{\tan x} dx = \int e^u du = e^u + C = e^{\tan x} + C$.

$$73. \int \frac{e^x + 1}{e^x} dx = \int (1 + e^{-x}) dx = x - e^{-x} + C$$

74. Let $u = \frac{1}{x}$. Then $du = -\frac{1}{x^2} dx$, so $\int \frac{e^{1/x}}{x^2} dx = -\int e^u du = -e^u + C = -e^{1/x} + C$.

75. Let $u = \sqrt{x}$. Then $du = \frac{1}{2\sqrt{x}} dx$, so $\int \frac{e^{\sqrt{x}}}{\sqrt{x}} dx = 2 \int e^u du = 2e^u + C = 2e^{\sqrt{x}} + C$.

76. Let $u = e^x$. Then $du = e^x dx$, so $\int e^x \sin(e^x) dx = \int \sin u du = -\cos u + C = -\cos(e^x) + C$.

77. Area = $\int_0^1 (e^{3x} - e^x) dx = [\frac{1}{3}e^{3x} - e^x]_0^1 = (\frac{1}{3}e^3 - e) - (\frac{1}{3} - 1) = \frac{1}{3}e^3 - e + \frac{2}{3} \approx 4.644$

78. $f''(x) = 3e^x + 5 \sin x \Rightarrow f'(x) = 3e^x - 5 \cos x + C \Rightarrow 2 = f'(0) = 3 - 5 + C \Rightarrow C = 4$, so

$$f'(x) = 3e^x - 5 \cos x + 4 \Rightarrow f(x) = 3e^x - 5 \sin x + 4x + D \Rightarrow 1 = f(0) = 3 + D \Rightarrow D = -2, \\ \text{so } f(x) = 3e^x - 5 \sin x + 4x - 2.$$

79. $V = \int_0^1 \pi (e^x)^2 dx = \pi \int_0^1 e^{2x} dx = \frac{1}{2} \pi [e^{2x}]_0^1 = \frac{\pi}{2} (e^2 - 1)$

80. $V = \int_0^1 2\pi x e^{-x^2} dx$. Let $u = x^2$. Thus $du = 2x dx$, so $V = \pi \int_0^1 e^{-u} du = \pi [-e^{-u}]_0^1 = \pi (1 - 1/e)$.

81. $y = \ln(x+3) \Rightarrow e^y = x+3 \Rightarrow$
 $x = e^y - 3$. Interchanging x and y , we get
 $y = e^x - 3$, so $f^{-1}(x) = e^x - 3$.

82. $y = \frac{1+e^x}{1-e^x} \Rightarrow y - ye^x = 1 + e^x \Rightarrow$
 $e^x(y+1) = y-1 \Rightarrow e^x = \frac{y-1}{y+1} \Rightarrow$
 $x = \ln\left(\frac{y-1}{y+1}\right)$. Interchange x and y :
 $y = \ln\left(\frac{x-1}{x+1}\right)$ is the inverse function.

83. We use Theorem 7.1.7. Note that $f(0) = 3 + 0 + e^0 = 4$, so $f^{-1}(4) = 0$. Also $f'(x) = 1 + e^x$. Therefore,

$$(f^{-1})'(4) = \frac{1}{f'(f^{-1}(4))} = \frac{1}{f'(0)} = \frac{1}{1+e^0} = \frac{1}{2}.$$

84. We recognize this limit as the definition of the derivative of the function $f(x) = e^{\sin x}$ at $x = \pi$, since it is of the form $\lim_{x \rightarrow \pi} \frac{f(x) - f(\pi)}{x - \pi}$. Therefore, the limit is equal to $f'(\pi) = (\cos \pi)e^{\sin \pi} = -1 \cdot e^0 = -1$.

85. Using the second law of logarithms and Equation 5, we have $\ln(e^x/e^y) = \ln e^x - \ln e^y = x - y = \ln(e^{x-y})$.

Since $\ln$ is a one-to-one function, it follows that $e^x/e^y = e^{x-y}$.

86. Using the third law of logarithms and Equation 5, we have $\ln e^{rx} = rx = r \ln e^x = \ln(e^x)^r$. Since $\ln$ is a one-to-one function, it follows that $e^{rx} = (e^x)^r$.

87. (a) Let $f(x) = e^x - 1 - x$. Now $f(0) = e^0 - 1 = 0$, and for $x \geq 0$, we have $f'(x) = e^x - 1 \geq 0$. Now, since $f(0) = 0$ and f is increasing on $[0, \infty)$, $f(x) \geq 0$ for $x \geq 0 \Rightarrow e^x - 1 - x \geq 0 \Rightarrow e^x \geq 1 + x$.

- (b) For $0 \leq x \leq 1$, $x^2 \leq x$, so $e^{x^2} \leq e^x$ [since e^x is increasing]. Hence [from (a)] $1 + x^2 \leq e^{x^2} \leq e^x$.

$$\text{So } \frac{4}{3} = \int_0^1 (1 + x^2) dx \leq \int_0^1 e^{x^2} dx \leq \int_0^1 e^x dx = e - 1 < e \Rightarrow \frac{4}{3} \leq \int_0^1 e^{x^2} dx \leq e.$$

88. (a) Let $f(x) = e^x - 1 - x - \frac{1}{2}x^2$. Thus, $f'(x) = e^x - 1 - x$, which is positive for $x \geq 0$ by Exercise 87(a).

Thus $f(x)$ is increasing on $(0, \infty)$, so on that interval, $0 = f(0) \leq f(x) = e^x - 1 - x - \frac{1}{2}x^2 \Rightarrow e^x \geq 1 + x + \frac{1}{2}x^2$.

- (b) Using the same argument as in Exercise 87(b), from part (a) we have $1 + x^2 + \frac{1}{2}x^4 \leq e^{x^2} \leq e^x$

$$[\text{for } 0 \leq x \leq 1] \Rightarrow \int_0^1 (1 + x^2 + \frac{1}{2}x^4) dx \leq \int_0^1 e^{x^2} dx \leq \int_0^1 e^x dx \Rightarrow \frac{43}{30} \leq \int_0^1 e^{x^2} dx \leq e - 1.$$

89. (a) By Exercise 87(a), the result holds for $n = 1$. Suppose that $e^x \geq 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^k}{k!}$ for $x \geq 0$.

Let $f(x) = e^x - 1 - x - \frac{x^2}{2!} - \cdots - \frac{x^k}{k!} - \frac{x^{k+1}}{(k+1)!}$. Then $f'(x) = e^x - 1 - x - \cdots - \frac{x^k}{k!} \geq 0$

by assumption. Hence $f(x)$ is increasing on $(0, \infty)$. So $0 \leq x$ implies that

$$0 = f(0) \leq f(x) = e^x - 1 - x - \cdots - \frac{x^k}{k!} - \frac{x^{k+1}}{(k+1)!}, \text{ and hence } e^x \geq 1 + x + \cdots + \frac{x^k}{k!} + \frac{x^{k+1}}{(k+1)!}$$

for $x \geq 0$. Therefore, for $x \geq 0$, $e^x \geq 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!}$ for every positive integer n , by mathematical induction.

- (b) Taking $n = 4$ and $x = 1$ in (a), we have $e = e^1 \geq 1 + \frac{1}{2} + \frac{1}{6} + \frac{1}{24} = 2.708\bar{3} > 2.7$.

$$(c) e^x \geq 1 + x + \cdots + \frac{x^k}{k!} + \frac{x^{k+1}}{(k+1)!} \Rightarrow \frac{e^x}{x^k} \geq \frac{1}{x^k} + \frac{1}{x^{k-1}} + \cdots + \frac{1}{k!} + \frac{x}{(k+1)!} \geq \frac{x}{(k+1)!}.$$

But $\lim_{x \rightarrow \infty} \frac{x}{(k+1)!} = \infty$, so $\lim_{x \rightarrow \infty} \frac{e^x}{x^k} = \infty$.

90. (a) The graph of g finally surpasses that of f at $x \approx 35.8$.

- (b) 3×10^{10}

- (c) From the graph in part (b), it seems that $e^x/x^{10} > 10^{10}$ whenever $x > 65$, approximately. So we can take $N \geq 65$.

7.4* General Logarithmic and Exponential Functions

1. (a) $a^x = e^{x \ln a}$

(b) The domain of $f(x) = a^x$ is $\mathbb{R}$.

(c) The range of $f(x) = a^x$ ($a \neq 1$) is $(0, \infty)$.

(d) (i) See Figure 1. (ii) See Figure 3. (iii) See Figure 2.

2. (a) $\log_a x$ is the number y such that $a^y = x$.

(b) The domain of $f(x) = \log_a x$ is $(0, \infty)$.

(c) The range of $f(x) = \log_a x$ is $\mathbb{R}$.

(d) See Figure 9.

3. $5^{\sqrt{7}} = (e^{\ln 5})^{\sqrt{7}} = e^{\sqrt{7} \ln 5}$

4. $10^{x^2} = (e^{\ln 10})^{x^2} = e^{x^2 \ln 10}$

5. $(\cos x)^x = (e^{\ln \cos x})^x = e^{x \ln(\cos x)}$.

6. $x^{\cos x} = (e^{\ln x})^{\cos x} = e^{(\cos x)(\ln x)}$

7. (a) $\log_{10} 1000 = 3$ because $10^3 = 1000$.

(b) $\log_2 \frac{1}{16} = -4$ since $2^{-4} = \frac{1}{16}$. [Or: $\log_2 \frac{1}{16} = \log_2 2^{-4} = -4$]

8. (a) $\log_{10} 0.1 = -1$ since $10^{-1} = 0.1$.

(b) $\log_8 320 - \log_8 5 = \log_8 \frac{320}{5} = \log_8 64 = 2$ since $8^2 = 64$.

9. (a) $\log_{12} 3 + \log_{12} 48 = \log_{12}(3 \cdot 48) = \log_{12} 144 = 2$ since $12^2 = 144$.

(b) $\log_5 5^{\sqrt{2}} = \sqrt{2}$ by the cancellation property $\log_a a^x = x$.

[Or: $\log_5 5^{\sqrt{2}} = \sqrt{2} \log_5 5 = \sqrt{2} \cdot 1 = \sqrt{2}$]

10. (a) $\log_a \frac{1}{a} = -1$ since $a^{-1} = \frac{1}{a}$. [Or: $\log_a \frac{1}{a} = \log_a a^{-1} = -1$]

(b) $10^{(\log_{10} 4 + \log_{10} 7)} = 10^{\log_{10} 4} \cdot 10^{\log_{10} 7} = 4 \cdot 7 = 28$

[Or: $10^{(\log_{10} 4 + \log_{10} 7)} = 10^{\log_{10}(4 \cdot 7)} = 10^{\log_{10} 28} = 28$]

11. All of these graphs approach 0 as $x \rightarrow -\infty$, all of them pass through the point $(0, 1)$, and all of them are increasing and approach ∞ as $x \rightarrow \infty$. The larger the base, the faster the function increases for $x > 0$, and the faster it approaches 0 as $x \rightarrow -\infty$.

12. The functions with bases greater than 1 (3^x and 10^x) are increasing, while those with bases less than 1

$\left[\left(\frac{1}{3}\right)^x \text{ and } \left(\frac{1}{10}\right)^x\right]$ are decreasing. The graph of $\left(\frac{1}{3}\right)^x$ is the

reflection of that of 3^x about the y -axis, and the graph of

$\left(\frac{1}{10}\right)^x$ is the reflection of that of 10^x about the y -axis. The

graph of 10^x increases more quickly than that of 3^x for

$x > 0$, and approaches 0 faster as $x \rightarrow -\infty$.

13. (a) $\log_{12} e = \frac{\ln e}{\ln 12} = \frac{1}{\ln 12} \approx 0.402430$

(b) $\log_6 13.54 = \frac{\ln 13.54}{\ln 6} \approx 1.454240$

(c) $\log_2 \pi = \frac{\ln \pi}{\ln 2} \approx 1.651496$

14. To graph the functions, we use $\log_2 x = \frac{\ln x}{\ln 2}$, $\log_4 x = \frac{\ln x}{\ln 4}$, etc.

These graphs all approach $-\infty$ as $x \rightarrow 0^+$, and they all pass through the point $(1, 0)$. Also, they are all increasing, and all approach ∞ as $x \rightarrow \infty$. The smaller the base, the larger the rate of increase of the function (for $x > 1$) and the closer the approach to the y -axis (as $x \rightarrow 0^+$).

15. To graph these functions, we use $\log_{1.5} x = \frac{\ln x}{\ln 1.5}$ and

$\log_{50} x = \frac{\ln x}{\ln 50}$. These graphs all approach $-\infty$ as $x \rightarrow 0^+$, and they all pass through the point $(1, 0)$. Also, they are all increasing, and all approach ∞ as $x \rightarrow \infty$. The functions with larger bases increase extremely slowly, and the ones with smaller bases do so somewhat more quickly. The functions with large bases approach the y -axis more closely as $x \rightarrow 0^+$.

16. We see that the graph of $\ln x$ is the reflection of the graph of e^x about the line $y = x$, and that the graph of $\log_{10} x$ is the reflection of the graph of 10^x about the same line. The graph of 10^x increases more quickly than that of e^x . Also note that $\log_{10} x \rightarrow \infty$ as $x \rightarrow \infty$ more slowly than $\ln x$.

17. Use $y = Ca^x$ with the points $(1, 6)$ and $(3, 24)$. $6 = Ca^1$ $[C = \frac{6}{a}]$ and $24 = Ca^3 \Rightarrow 24 = (\frac{6}{a})a^3 \Rightarrow 4 = a^2 \Rightarrow a = 2$ [since $a > 0$] and $C = \frac{6}{2} = 3$. The function is $f(x) = 3 \cdot 2^x$.

18. Given the y -intercept $(0, 2)$, we have $y = Ca^x = 2a^x$. Using the point $(2, \frac{2}{9})$ gives us $\frac{2}{9} = 2a^2 \Rightarrow \frac{1}{9} = a^2 \Rightarrow a = \frac{1}{3}$ [since $a > 0$]. The function is $f(x) = 2(\frac{1}{3})^x$ or $f(x) = 2(3)^{-x}$.

19. (a) $2 \text{ ft} = 24 \text{ in}$, $f(24) = 24^2 \text{ in} = 576 \text{ in} = 48 \text{ ft}$. $g(24) = 2^{24} \text{ in} = 2^{24}/(12 \cdot 5280) \text{ mi} \approx 265 \text{ mi}$

(b) $3 \text{ ft} = 36 \text{ in}$, so we need x such that $\log_2 x = 36 \Leftrightarrow x = 2^{36} = 68,719,476,736$. In miles, this is

$$68,719,476,736 \text{ in} \cdot \frac{1 \text{ ft}}{12 \text{ in}} \cdot \frac{1 \text{ mi}}{5280 \text{ ft}} \approx 1,084,587.7 \text{ mi}.$$

20. We see from the graphs that for x less than about 1.8, $g(x) = 5^x > f(x) = x^5$, and then near the point (1.8, 17.1) the curves intersect. Then $f(x) > g(x)$ from $x \approx 1.8$ until $x = 5$. At (5, 3125) there is another point of intersection, and for $x > 5$ we see that $g(x) > f(x)$. In fact, g increases much more rapidly than f beyond that point.

21. $\lim_{t \rightarrow \infty} 2^{-t^2} = \lim_{u \rightarrow -\infty} 2^u$ [where $u = -t^2$] $= 0$
22. Let $t = x^2 - 5x + 6$. As $x \rightarrow 3^+$, $t = (x-2)(x-3) \rightarrow 0^+$. $\lim_{x \rightarrow 3^+} \log_{10}(x^2 - 5x + 6) = \lim_{t \rightarrow 0^+} \log_{10} t = -\infty$ by (4) in Section 7.3.
23. $h(t) = t^3 - 3^t \Rightarrow h'(t) = 3t^2 - 3^t \ln 3$
24. $g(x) = x^4 4^x \Rightarrow g'(x) = x^4 4^x \ln 4 + 4^x \cdot 4x^3 = x^3 4^x (x \ln 4 + 4)$
25. Using Formula 4 and the Chain Rule, $y = 5^{-1/x} \Rightarrow y' = 5^{-1/x} (\ln 5) [-1 \cdot (-x^{-2})] = 5^{-1/x} (\ln 5) / x^2$
26. $y = 10^{\tan \theta} \Rightarrow y' = 10^{\tan \theta} (\ln 10) (\sec^2 \theta)$
27. $f(u) = (2^u + 2^{-u})^{10} \Rightarrow$
 $f'(u) = 10(2^u + 2^{-u})^9 \frac{d}{du} (2^u + 2^{-u}) = 10(2^u + 2^{-u})^9 [2^u \ln 2 + 2^{-u} \ln 2 \cdot (-1)]$
 $= 10 \ln 2 (2^u + 2^{-u})^9 (2^u - 2^{-u})$
28. $y = 2^{3x^2} \Rightarrow y' = 2^{3x^2} (\ln 2) \frac{d}{dx} (3x^2) = 2^{3x^2} (\ln 2) 3x^2 (\ln 3) (2x)$
29. $f(x) = \log_3(x^2 - 4) \Rightarrow f'(x) = \frac{1}{(x^2 - 4) \ln 3} (2x) = \frac{2x}{(x^2 - 4) \ln 3}$
30. $f(x) = \log_{10} \left(\frac{x}{x-1} \right) = \log_{10} x - \log_{10}(x-1) \Rightarrow f'(x) = \frac{1}{x \ln 10} - \frac{1}{(x-1) \ln 10}$ or $-\frac{1}{x(x-1) \ln 10}$
31. $y = x^x \Rightarrow \ln y = x \ln x \Rightarrow y'/y = \ln x + x(1/x) \Rightarrow y' = x^x (\ln x + 1)$
32. $y = x^{1/x} \Rightarrow \ln y = \frac{1}{x} \ln x \Rightarrow \frac{y'}{y} = -\frac{1}{x^2} \ln x + \frac{1}{x} \left(\frac{1}{x} \right) \Rightarrow y' = x^{1/x} \frac{1 - \ln x}{x^2}$
33. $y = x^{\sin x} \Rightarrow \ln y = \sin x \ln x \Rightarrow \frac{y'}{y} = \cos x \ln x + \frac{\sin x}{x} \Rightarrow y' = x^{\sin x} \left(\cos x \ln x + \frac{\sin x}{x} \right)$

$$34. y = (\sin x)^x \Rightarrow \ln y = x \ln(\sin x) \Rightarrow y'/y = \ln(\sin x) + x(\cos x)/(\sin x) \Rightarrow y' = (\sin x)^x [\ln(\sin x) + x \cot x]$$

$$35. y = (\ln x)^x \Rightarrow \ln y = x \ln \ln x \Rightarrow \frac{y'}{y} = \ln \ln x + x \cdot \frac{1}{\ln x} \cdot \frac{1}{x} \Rightarrow y' = (\ln x)^x \left(\ln \ln x + \frac{1}{\ln x} \right)$$

$$36. y = x^{\ln x} \Rightarrow \ln y = \ln x \ln x = (\ln x)^2 \Rightarrow \frac{y'}{y} = 2 \ln x \left(\frac{1}{x} \right) \Rightarrow y' = x^{\ln x} \left(\frac{2 \ln x}{x} \right)$$

$$37. y = x^{e^x} \Rightarrow \ln y = e^x \ln x \Rightarrow \frac{y'}{y} = e^x \ln x + \frac{e^x}{x} \Rightarrow y' = x^{e^x} e^x \left(\ln x + \frac{1}{x} \right)$$

$$38. y = (\ln x)^{\cos x} \Rightarrow \ln y = \cos x \ln(\ln x) \Rightarrow \frac{y'}{y} = \cos x \cdot \frac{1}{\ln x} \cdot \frac{1}{x} + (\ln \ln x)(-\sin x) \Rightarrow y' = (\ln x)^{\cos x} \left(\frac{\cos x}{x \ln x} - \sin x \ln \ln x \right)$$

$$39. y = 10^x \Rightarrow y' = 10^x \ln 10, \text{ so at } (1, 10), \text{ the slope of the tangent line is } 10^1 \ln 10 = 10 \ln 10, \text{ and its equation is } y - 10 = 10 \ln 10(x - 1), \text{ or } y = (10 \ln 10)x + 10(1 - \ln 10).$$

$$40. f(x) = x^{\cos x} = e^{\ln x \cos x} \Rightarrow$$

$$f'(x) = e^{\ln x \cos x} \left[\ln x (-\sin x) + \cos x \left(\frac{1}{x} \right) \right] = x^{\cos x} \left[\frac{\cos x}{x} - \sin x \ln x \right]$$

This is reasonable, because the graph shows that f increases when $f'(x)$ is positive.

$$41. \int_1^{10} 10^t dt = \left[\frac{10^t}{\ln 10} \right]_1^{10} = \frac{10^{10}}{\ln 10} - \frac{10^1}{\ln 10} = \frac{100 - 10}{\ln 10} = \frac{90}{\ln 10}$$

$$42. \text{ Let } v = -2u. \text{ Then } dv = -2 du \text{ and}$$

$$\int_0^1 4^{-2u} du = \int_0^{-2} 4^v \left(-\frac{1}{2} \right) dv = -\frac{1}{2} \left[\frac{4^v}{\ln 4} \right]_0^{-2} = -\frac{1}{2 \ln 4} (4^{-2} - 4^0) = -\frac{1}{2 \ln 2^2} \left(\frac{1}{16} - 1 \right) = -\frac{1}{4 \ln 2} \left(-\frac{15}{16} \right) = \frac{15}{64 \ln 2}$$

$$43. \int \frac{\log_{10} x}{x} dx = \int \frac{(\ln x)/(\ln 10)}{x} dx = \frac{1}{\ln 10} \int \frac{\ln x}{x} dx. \text{ Now put } u = \ln x, \text{ so } du = \frac{1}{x} dx, \text{ and the expression becomes } \frac{1}{\ln 10} \int u du = \frac{1}{\ln 10} \left(\frac{1}{2} u^2 + C_1 \right) = \frac{1}{2 \ln 10} (\ln x)^2 + C.$$

$$\text{Or: The substitution } u = \log_{10} x \text{ gives } du = \frac{dx}{x \ln 10} \text{ and we get } \int \frac{\log_{10} x}{x} dx = \frac{1}{2} \ln 10 (\log_{10} x)^2 + C.$$

$$44. \int (x^5 + 5^x) dx = \frac{1}{6} x^6 + \frac{1}{\ln 5} 5^x + C$$

$$45. \text{ Let } u = \sin \theta. \text{ Then } du = \cos \theta d\theta \text{ and } \int 3^{\sin \theta} \cos \theta d\theta = \int 3^u du = \frac{3^u}{\ln 3} + C = \frac{1}{\ln 3} 3^{\sin \theta} + C.$$

$$46. \text{ Let } u = 2^x + 1. \text{ Then } du = 2^x \ln 2 dx, \text{ so } \int \frac{2^x}{2^x + 1} dx = \int \frac{1}{u} \frac{du}{\ln 2} = \frac{1}{\ln 2} \ln |u| + C = \frac{1}{\ln 2} \ln(2^x + 1) + C.$$

$$\begin{aligned}
 47. A &= \int_{-1}^0 (2^x - 5^x) dx + \int_0^1 (5^x - 2^x) dx \\
 &= \left[\frac{2^x}{\ln 2} - \frac{5^x}{\ln 5} \right]_{-1}^0 + \left[\frac{5^x}{\ln 5} - \frac{2^x}{\ln 2} \right]_0^1 \\
 &= \left(\frac{1}{\ln 2} - \frac{1}{\ln 5} \right) - \left(\frac{1/2}{\ln 2} - \frac{1/5}{\ln 5} \right) + \left(\frac{5}{\ln 5} - \frac{2}{\ln 2} \right) - \left(\frac{1}{\ln 5} - \frac{1}{\ln 2} \right) \\
 &= \frac{16}{5 \ln 5} - \frac{1}{2 \ln 2}
 \end{aligned}$$

48. Using disks, the volume is $V = \int_0^1 \pi [10^{-x}]^2 dx = \pi \int_0^1 10^{-2x} dx$. To evaluate the integral, we let $u = -2x \Rightarrow du = -2 dx$, $x = 0 \Rightarrow u = 0$, and $x = 1 \Rightarrow u = -2$, so we have

$$V = -\frac{\pi}{2} \int_0^{-2} 10^u du = -\frac{\pi}{2} \left[\frac{1}{\ln 10} 10^u \right]_0^{-2} = -\frac{\pi}{2 \ln 10} (10^{-2} - 1) = \frac{99\pi}{200 \ln 10}$$

49. We see that the graphs of $y = 2^x$ and $y = 1 + 3^{-x}$ intersect at $x \approx 0.6$. We let $f(x) = 2^x - 1 - 3^{-x}$ and calculate $f'(x) = 2^x \ln 2 + 3^{-x} \ln 3$, and using the formula $x_{n+1} = x_n - f(x_n)/f'(x_n)$ (Newton's Method), we get $x_1 = 0.6$, $x_2 \approx x_3 \approx 0.600967$. So, correct to six decimal places, the root occurs at $x = 0.600967$.

50. $x^y = y^x \Rightarrow y \ln x = x \ln y \Rightarrow y \cdot \frac{1}{x} + (\ln x) \cdot y' = x \cdot \frac{1}{y} \cdot y' + \ln y \Rightarrow y' \ln x - \frac{x}{y} y' = \ln y - \frac{y}{x} \Rightarrow$
 $y' = \frac{\ln y - y/x}{\ln x - x/y}$

51. $y = \frac{10^x}{10^x + 1} \Leftrightarrow (10^x + 1)y = 10^x \Leftrightarrow 10^x \cdot y + y = 10^x \Leftrightarrow y = 10^x - 10^x y \Leftrightarrow$
 $y = 10^x(1 - y) \Leftrightarrow 10^x = \frac{y}{1 - y} \Leftrightarrow \log_{10} 10^x = \log_{10} \left(\frac{y}{1 - y} \right) \Leftrightarrow x = \log_{10} y - \log_{10}(1 - y).$
 Interchange x and y : $y = \log_{10} x - \log_{10}(1 - x)$ is the inverse function.

52. $\lim_{x \rightarrow 0^+} x^{-\ln x} = \lim_{x \rightarrow 0^+} (e^{\ln x})^{-\ln x} = \lim_{x \rightarrow 0^+} e^{-(\ln x)^2} = 0$ since $-(\ln x)^2 \rightarrow -\infty$ as $x \rightarrow 0^+$.

53. If I is the intensity of the 1989 San Francisco earthquake, then $\log_{10}(I/S) = 7.1 \Rightarrow$
 $\log_{10}(16I/S) = \log_{10} 16 + \log_{10}(I/S) = \log_{10} 16 + 7.1 \approx 8.3.$

54. Let I_1 and I_2 be the intensities of the music and the mower. Then $10 \log_{10} \left(\frac{I_1}{I_0} \right) = 120$ and $10 \log_{10} \left(\frac{I_2}{I_0} \right) = 106$,
 so $\log_{10} \left(\frac{I_1}{I_2} \right) = \log_{10} \left(\frac{I_1/I_0}{I_2/I_0} \right) = \log_{10} \left(\frac{I_1}{I_0} \right) - \log_{10} \left(\frac{I_2}{I_0} \right) = 12 - 10.6 = 1.4 \Rightarrow \frac{I_1}{I_2} = 10^{1.4} \approx 25.$

55. We find I with the loudness formula from Exercise 55, substituting $I_0 = 10^{-12}$ and $L = 50$:

$$50 = 10 \log_{10} \frac{I}{10^{-12}} \Leftrightarrow 5 = \log_{10} \frac{I}{10^{-12}} \Leftrightarrow 10^5 = \frac{I}{10^{-12}} \Leftrightarrow I = 10^{-7} \text{ watt/m}^2. \text{ Now we}$$

$$\text{differentiate } L \text{ with respect to } I: L = 10 \log_{10} \frac{I}{I_0} \Rightarrow \frac{dL}{dI} = 10 \frac{1}{(I/I_0) \ln 10} \left(\frac{1}{I_0} \right) = \frac{10}{\ln 10} \left(\frac{1}{I} \right).$$

$$\text{Substituting } I = 10^{-7}, \text{ we get } L'(50) = \frac{10}{\ln 10} \left(\frac{1}{10^{-7}} \right) = \frac{10^8}{\ln 10} \approx 4.34 \times 10^7 \frac{\text{dB}}{\text{watt/m}^2}.$$

56. (a) $I(x) = I_0 a^x \Rightarrow I'(x) = I_0 (\ln a) a^x = (I_0 a^x) \ln a = I(x) \ln a$

(b) We substitute $I_0 = 8$, $a = 0.38$ and $x = 20$ into the first expression for $I'(x)$ above:

$$I'(20) = 8(\ln 0.38)(0.38)^{20} \approx -3.05 \times 10^{-8}.$$

(c) The average value of the function $I(x)$ between $x = 0$ and $x = 20$ is

$$\frac{\int_0^{20} I(x) dx}{20 - 0} = \frac{1}{20} \int_0^{20} 8(0.38)^x dx = \frac{2}{5} \left[\frac{(0.38)^x}{\ln 0.38} \right]_0^{20} = \frac{2(0.38^{20} - 1)}{5 \ln 0.38} \approx 0.41.$$

57. (a) Using a calculator or CAS, we obtain the model $Q = ab^t$ with $a = 100.0124369$ and $b = 0.000045145933$.

We can change this model to one with base e and exponent $\ln b$ [$b^t = e^{t \ln b}$ from precalculus mathematics or from Section 7.3]: $Q = ae^{t \ln b} = 100.012437e^{-10.005531t}$.

(b) Use $Q'(t) = ab^t \ln b$ or the calculator command `nDeriv(Y1, X, .04)` with $Y_1 = ab^x$ to get

$$Q'(0.04) \approx -670.63 \mu\text{A}. \text{ The result of Example 2 in Section 2.1 was } -670 \mu\text{A}.$$

58. (a) $P = ab^t$ with $a = 4.502714 \times 10^{-20}$ and $b = 1.029953851$,

where P is measured in thousands of people. The fit appears to be very good.

(b) For 1800: $m_1 = \frac{5308 - 3929}{1800 - 1790} = 137.9$, $m_2 = \frac{7240 - 5308}{1810 - 1800} = 193.2$.

$$\text{So } P'(1800) \approx (m_1 + m_2)/2 = 165.55 \text{ thousand people/year.}$$

For 1850: $m_1 = \frac{23,192 - 17,063}{1850 - 1840} = 612.9$, $m_2 = \frac{31,443 - 23,192}{1860 - 1850} = 825.1$.

$$\text{So } P'(1850) \approx (m_1 + m_2)/2 = 719 \text{ thousand people/year.}$$

(c) Use the calculator command `nDeriv(Y1, X, year)` with $Y_1 = ab^x$ to get

$$P'(1800) \approx 156.85 \text{ and } P'(1850) \approx 686.07. \text{ These estimates are somewhat less than the ones in part (b).}$$

(d) $P(1870) \approx 41,946.56$. The difference of 3.4 million people is most likely due to the Civil War (1861–1865).

59. Using Definition 1 and the second law of exponents for e^x , we have

$$a^{x-y} = e^{(x-y) \ln a} = e^{x \ln a - y \ln a} = \frac{e^{x \ln a}}{e^{y \ln a}} = \frac{a^x}{a^y}.$$

60. Using Definition 1, the first law of logarithms, and the first law of exponents for e^x , we have

$$(ab)^x = e^{x \ln(ab)} = e^{x(\ln a + \ln b)} = e^{x \ln a + x \ln b} = e^{x \ln a} e^{x \ln b} = a^x b^x.$$

61. Let $\log_a x = r$ and $\log_a y = s$. Then $a^r = x$ and $a^s = y$.

(a) $xy = a^r a^s = a^{r+s} \Rightarrow \log_a(xy) = r + s = \log_a x + \log_a y$

(b) $\frac{x}{y} = \frac{a^r}{a^s} = a^{r-s} \Rightarrow \log_a \frac{x}{y} = r - s = \log_a x - \log_a y$

(c) $x^y = (a^r)^y = a^{ry} \Rightarrow \log_a(x^y) = ry = y \log_a x$

62. Let $m = n/x$. Then $n = xm$, and as $n \rightarrow \infty$, $m \rightarrow \infty$.

$$\text{Therefore, } \lim_{n \rightarrow \infty} \left(1 + \frac{x}{n}\right)^n = \lim_{m \rightarrow \infty} \left(1 + \frac{1}{m}\right)^{mx} = \left[\lim_{m \rightarrow \infty} \left(1 + \frac{1}{m}\right)^m \right]^x = e^x \text{ by Equation 9.}$$

7.5 Inverse Trigonometric Functions

1. (a) $\sin^{-1}\left(\frac{\sqrt{3}}{2}\right) = \frac{\pi}{3}$ since $\sin \frac{\pi}{3} = \frac{\sqrt{3}}{2}$ and $\frac{\pi}{3}$ is in $[-\frac{\pi}{2}, \frac{\pi}{2}]$.
 (b) $\cos^{-1}(-1) = \pi$ since $\cos \pi = -1$ and π is in $[0, \pi]$.
2. (a) $\arctan(-1) = -\frac{\pi}{4}$ since $\tan(-\frac{\pi}{4}) = -1$ and $-\frac{\pi}{4}$ is in $(-\frac{\pi}{2}, \frac{\pi}{2})$.
 (b) $\csc^{-1} 2 = \frac{\pi}{6}$ since $\csc \frac{\pi}{6} = 2$ and $\frac{\pi}{6}$ is in $(0, \frac{\pi}{2}] \cup (\pi, \frac{3\pi}{2}]$.
3. (a) $\tan^{-1} \sqrt{3} = \frac{\pi}{3}$ since $\tan \frac{\pi}{3} = \sqrt{3}$ and $\frac{\pi}{3}$ is in $(-\frac{\pi}{2}, \frac{\pi}{2})$.
 (b) $\arcsin\left(-\frac{1}{\sqrt{2}}\right) = -\frac{\pi}{4}$ since $\sin(-\frac{\pi}{4}) = -\frac{1}{\sqrt{2}}$ and $-\frac{\pi}{4}$ is in $[-\frac{\pi}{2}, \frac{\pi}{2}]$.
4. (a) $\sec^{-1} \sqrt{2} = \frac{\pi}{4}$ since $\sec \frac{\pi}{4} = \sqrt{2}$ and $\frac{\pi}{4}$ is in $[0, \frac{\pi}{2}) \cup [\pi, \frac{3\pi}{2})$.
 (b) $\arcsin 1 = \frac{\pi}{2}$ since $\sin \frac{\pi}{2} = 1$ and $\frac{\pi}{2}$ is in $[-\frac{\pi}{2}, \frac{\pi}{2}]$.
5. (a) $\arccos(\cos 2\pi) = \arccos(1) = 0$
 (b) $\tan(\tan^{-1} 5) = 5$
6. (a) $\tan^{-1}\left(\tan \frac{3\pi}{4}\right) = \tan^{-1}(-1) = -\frac{\pi}{4}$
 (b) $\cos\left(\arcsin \frac{1}{2}\right) = \cos\left(\frac{\pi}{6}\right) = \frac{\sqrt{3}}{2}$

7. Let $\theta = \sin^{-1}\left(\frac{2}{3}\right)$.

Then $\tan(\sin^{-1}(\frac{2}{3})) = \tan \theta = \frac{2}{\sqrt{5}}$.

8. Let $\theta = \arccos \frac{3}{5}$.

Then $\csc(\arccos(\frac{3}{5})) = \csc \theta = \frac{5}{4}$.

9. Let $\theta = \tan^{-1} \sqrt{2}$. Then

$$\begin{aligned} \sin(2 \tan^{-1} \sqrt{2}) &= \sin(2\theta) = 2 \sin \theta \cos \theta \\ &= 2 \left(\frac{\sqrt{2}}{\sqrt{3}} \right) \left(\frac{1}{\sqrt{3}} \right) = \frac{2\sqrt{2}}{3} \end{aligned}$$

10. Let $x = \tan^{-1} 2$ and $y = \tan^{-1} 3$. Then

$$\begin{aligned}\cos(\tan^{-1} 2 + \tan^{-1} 3) &= \cos(x + y) = \cos x \cos y - \sin x \sin y \\&= \frac{1}{\sqrt{5}} \frac{1}{\sqrt{10}} - \frac{2}{\sqrt{5}} \frac{3}{\sqrt{10}} \\&= \frac{-5}{\sqrt{50}} = \frac{-5}{5\sqrt{2}} = \frac{-1}{\sqrt{2}}\end{aligned}$$

11. Let $y = \sin^{-1} x$. Then $-\frac{\pi}{2} \leq y \leq \frac{\pi}{2} \Rightarrow \cos y \geq 0$, so $\cos(\sin^{-1} x) = \cos y = \sqrt{1 - \sin^2 y} = \sqrt{1 - x^2}$

12. Let $y = \sin^{-1} x$. Then $\sin y = x$, so from the triangle we see that

$$\tan(\sin^{-1} x) = \tan y = \frac{x}{\sqrt{1-x^2}}.$$

13. Let $y = \tan^{-1} x$. Then $\tan y = x$, so from the triangle we see that

$$\sin(\tan^{-1} x) = \sin y = \frac{x}{\sqrt{1+x^2}}.$$

14. Let $\theta = \arctan 2x$. Then $\tan \theta = 2x$, so from the diagram we see that

$$\csc(\arctan 2x) = \csc \theta = \frac{\sqrt{4x^2 + 1}}{2x}.$$

15.

The graph of $\sin^{-1} x$ is the reflection of the graph of $\sin x$ about the line $y = x$.

16.

The graph of $\tan^{-1} x$ is the reflection of the graph of $\tan x$ about the line $y = x$.

17. Let $y = \cos^{-1} x$. Then $\cos y = x$ and $0 \leq y \leq \pi \Rightarrow -\sin y \frac{dy}{dx} = 1 \Rightarrow$

$$\frac{dy}{dx} = -\frac{1}{\sin y} = -\frac{1}{\sqrt{1 - \cos^2 y}} = -\frac{1}{\sqrt{1 - x^2}}. \quad [\text{Note that } \sin y \geq 0 \text{ for } 0 \leq y \leq \pi.]$$

18. (a) Let $a = \sin^{-1} x$ and $b = \cos^{-1} x$. Then $\cos a = \sqrt{1 - \sin^2 a} = \sqrt{1 - x^2}$ since $\cos a \geq 0$ for $-\frac{\pi}{2} \leq a \leq \frac{\pi}{2}$. Similarly, $\sin b = \sqrt{1 - x^2}$. So

$$\begin{aligned}\sin(\sin^{-1} x + \cos^{-1} x) &= \sin(a + b) = \sin a \cos b + \cos a \sin b = x \cdot x + \sqrt{1 - x^2} \sqrt{1 - x^2} \\ &= x^2 + (1 - x^2) = 1\end{aligned}$$

But $-\frac{\pi}{2} \leq \sin^{-1} x + \cos^{-1} x \leq \frac{3\pi}{2}$, and so $\sin^{-1} x + \cos^{-1} x = \frac{\pi}{2}$.

- (b) We differentiate $\sin^{-1} x + \cos^{-1} x = \frac{\pi}{2}$ with respect to x , and get

$$\frac{1}{\sqrt{1-x^2}} + \frac{d}{dx} \cos^{-1} x = 0 \Rightarrow \frac{d}{dx} \cos^{-1} x = -\frac{1}{\sqrt{1-x^2}}.$$

19. Let $y = \cot^{-1} x$. Then $\cot y = x \Rightarrow -\csc^2 y \frac{dy}{dx} = 1 \Rightarrow \frac{dy}{dx} = -\frac{1}{\csc^2 y} = -\frac{1}{1 + \cot^2 y} = -\frac{1}{1 + x^2}$.

20. Let $y = \sec^{-1} x$. Then $\sec y = x$ and $y \in (0, \frac{\pi}{2}] \cup [\pi, \frac{3\pi}{2})$. Differentiate with respect to x :

$$\sec y \tan y \left(\frac{dy}{dx} \right) = 1 \Rightarrow \frac{dy}{dx} = \frac{1}{\sec y \tan y} = \frac{1}{\sec y \sqrt{\sec^2 y - 1}} = \frac{1}{x \sqrt{x^2 - 1}}. \text{ Note that}$$

$$\tan^2 y = \sec^2 y - 1 \Rightarrow \tan y = \sqrt{\sec^2 y - 1} \text{ since } \tan y > 0 \text{ when } 0 < y < \frac{\pi}{2} \text{ or } \pi < y < \frac{3\pi}{2}.$$

21. Let $y = \csc^{-1} x$. Then $\csc y = x \Rightarrow -\csc y \cot y \frac{dy}{dx} = 1 \Rightarrow$

$$\frac{dy}{dx} = -\frac{1}{\csc y \cot y} = -\frac{1}{\csc y \sqrt{\csc^2 y - 1}} = -\frac{1}{x \sqrt{x^2 - 1}}. \text{ Note that } \cot y \geq 0 \text{ on the domain of } \csc^{-1} x.$$

22. $y = \sqrt{\tan^{-1} x} = (\tan^{-1} x)^{1/2} \Rightarrow$

$$y' = \frac{1}{2} (\tan^{-1} x)^{-1/2} \cdot \frac{d}{dx} (\tan^{-1} x) = \frac{1}{2 \sqrt{\tan^{-1} x}} \cdot \frac{1}{1 + x^2} = \frac{1}{2 \sqrt{\tan^{-1} x} (1 + x^2)}$$

23. $y = \tan^{-1} \sqrt{x} \Rightarrow y' = \frac{1}{1 + (\sqrt{x})^2} \cdot \frac{d}{dx} (\sqrt{x}) = \frac{1}{1 + x} \left(\frac{1}{2} x^{-1/2} \right) = \frac{1}{2 \sqrt{x} (1 + x)}$

24. $h(x) = \sqrt{1 - x^2} \arcsin x \Rightarrow$

$$h'(x) = \sqrt{1 - x^2} \cdot \frac{1}{\sqrt{1 - x^2}} + \arcsin x \left[\frac{1}{2} (1 - x^2)^{-1/2} (-2x) \right] = 1 - \frac{x \arcsin x}{\sqrt{1 - x^2}}$$

25. $y = \sin^{-1}(2x + 1) \Rightarrow$

$$y' = \frac{1}{\sqrt{1 - (2x + 1)^2}} \cdot \frac{d}{dx} (2x + 1) = \frac{1}{\sqrt{1 - (4x^2 + 4x + 1)}} \cdot 2 = \frac{2}{\sqrt{-4x^2 - 4x}} = \frac{1}{\sqrt{-x^2 - x}}$$

26. $f(x) = x \ln(\arctan x) \Rightarrow$

$$f'(x) = x \cdot \frac{1}{\arctan x} \cdot \frac{1}{1 + x^2} + \ln(\arctan x) \cdot 1 = \frac{x}{(1 + x^2) \arctan x} + \ln(\arctan x)$$

27. $H(x) = (1 + x^2) \arctan x \Rightarrow H'(x) = (1 + x^2) \frac{1}{1 + x^2} + (\arctan x)(2x) = 1 + 2x \arctan x$

28. $h(t) = e^{\sec^{-1} t} \Rightarrow h'(t) = e^{\sec^{-1} t} \frac{d}{dt} (\sec^{-1} t) = \frac{e^{\sec^{-1} t}}{t \sqrt{t^2 - 1}}$

29. $y = \cos^{-1}(e^{2x}) \Rightarrow y' = -\frac{1}{\sqrt{1 - (e^{2x})^2}} \cdot \frac{d}{dx} (e^{2x}) = -\frac{2e^{2x}}{\sqrt{1 - e^{4x}}}$

30. $y = x \cos^{-1} x - \sqrt{1 - x^2} \Rightarrow y' = \cos^{-1} x - \frac{x}{\sqrt{1 - x^2}} + \frac{x}{\sqrt{1 - x^2}} = \cos^{-1} x$

$$31. y = \arctan(\cos \theta) \Rightarrow y' = \frac{1}{1 + (\cos \theta)^2} (-\sin \theta) = -\frac{\sin \theta}{1 + \cos^2 \theta}$$

$$\begin{aligned}
 32. y = \tan^{-1}(x - \sqrt{x^2 + 1}) &\Rightarrow \\
 y' &= \frac{1}{1 + (x - \sqrt{x^2 + 1})^2} \left(1 - \frac{x}{\sqrt{x^2 + 1}}\right) = \frac{1}{1 + x^2 - 2x\sqrt{x^2 + 1} + x^2 + 1} \left(\frac{\sqrt{x^2 + 1} - x}{\sqrt{x^2 + 1}}\right) \\
 &= \frac{\sqrt{x^2 + 1} - x}{2(1 + x^2 - x\sqrt{x^2 + 1})\sqrt{x^2 + 1}} = \frac{\sqrt{x^2 + 1} - x}{2[\sqrt{x^2 + 1}(1 + x^2) - x(x^2 + 1)]} \\
 &= \frac{\sqrt{x^2 + 1} - x}{2[(1 + x^2)(\sqrt{x^2 + 1} - x)]} = \frac{1}{2(1 + x^2)}
 \end{aligned}$$

$$\begin{aligned}
 33. h(t) &= \cot^{-1}(t) + \cot^{-1}(1/t) \Rightarrow \\
 h'(t) &= -\frac{1}{1+t^2} - \frac{1}{1+(1/t)^2} \cdot \frac{d}{dt} \frac{1}{t} = -\frac{1}{1+t^2} - \frac{t^2}{t^2+1} \cdot \left(-\frac{1}{t^2}\right) = -\frac{1}{1+t^2} + \frac{1}{t^2+1} = 0.
 \end{aligned}$$

Note that this makes sense because $h(t) = \frac{\pi}{2}$ for $t > 0$ and $h(t) = -\frac{\pi}{2}$ for $t < 0$.

$$\begin{aligned}
 34. y &= \tan^{-1}\left(\frac{x}{a}\right) + \ln \sqrt{\frac{x-a}{x+a}} = \tan^{-1}\left(\frac{x}{a}\right) + \frac{1}{2} \ln(x-a) - \frac{1}{2} \ln(x+a) \Rightarrow \\
 y' &= \frac{a}{x^2+a^2} + \frac{1/2}{x-a} - \frac{1/2}{x+a} = \frac{a}{x^2+a^2} + \frac{a}{x^2-a^2} = \frac{2ax^2}{x^4-a^4}
 \end{aligned}$$

$$\begin{aligned}
 35. y &= \arccos\left(\frac{b+a\cos x}{a+b\cos x}\right) \Rightarrow \\
 y' &= -\frac{1}{\sqrt{1-\left(\frac{b+a\cos x}{a+b\cos x}\right)^2}} \frac{(a+b\cos x)(-a\sin x) - (b+a\cos x)(-b\sin x)}{(a+b\cos x)^2} \\
 &= \frac{1}{\sqrt{a^2+b^2\cos^2 x - b^2 - a^2\cos^2 x}} \frac{(a^2-b^2)\sin x}{|a+b\cos x|} \\
 &= \frac{1}{\sqrt{a^2-b^2}\sqrt{1-\cos^2 x}} \frac{(a^2-b^2)\sin x}{|a+b\cos x|} = \frac{\sqrt{a^2-b^2}\sin x}{|a+b\cos x||\sin x|}
 \end{aligned}$$

But $0 \leq x \leq \pi$, so $|\sin x| = \sin x$. Also $a > b > 0 \Rightarrow b\cos x \geq -b > -a$, so $a+b\cos x > 0$.

Thus $y' = \frac{\sqrt{a^2-b^2}}{a+b\cos x}$.

$$\begin{aligned}
 36. f(x) &= \arcsin(e^x) \Rightarrow f'(x) = \frac{1}{\sqrt{1-(e^x)^2}} \cdot e^x = \frac{e^x}{\sqrt{1-e^{2x}}}. \\
 \text{Domain}(f) &= \{x \mid -1 \leq e^x \leq 1\} = \{x \mid 0 < e^x \leq 1\} = (-\infty, 0]. \\
 \text{Domain}(f') &= \{x \mid 1 - e^{2x} > 0\} = \{x \mid e^{2x} < 1\} = \{x \mid 2x < 0\} = (-\infty, 0).
 \end{aligned}$$

$$\begin{aligned}
 37. g(x) &= \cos^{-1}(3-2x) \Rightarrow g'(x) = -\frac{1}{\sqrt{1-(3-2x)^2}} (-2) = \frac{2}{\sqrt{1-(3-2x)^2}}. \\
 \text{Domain}(g) &= \{x \mid -1 \leq 3-2x \leq 1\} = \{x \mid -4 \leq -2x \leq -2\} = \{x \mid 2 \geq x \geq 1\} = [1, 2]. \\
 \text{Domain}(g') &= \{x \mid 1 - (3-2x)^2 > 0\} = \{x \mid (3-2x)^2 < 1\} = \{x \mid |3-2x| < 1\} \\
 &= \{x \mid -1 < 3-2x < 1\} = \{x \mid -4 < -2x < -2\} = \{x \mid 2 > x > 1\} = (1, 2)
 \end{aligned}$$

$$38. \tan^{-1}(xy) = 1 + x^2y \Rightarrow \frac{1}{1+x^2y^2}(xy' + y \cdot 1) = 0 + x^2y' + 2xy \Rightarrow$$

$$y' \left(\frac{x}{1+x^2y^2} - x^2 \right) = 2xy - \frac{y}{1+x^2y^2} \Rightarrow$$

$$y' = \frac{2xy - \frac{y}{1+x^2y^2}}{\frac{x}{1+x^2y^2} - x^2} = \frac{2xy(1+x^2y^2) - y}{x - x^2(1+x^2y^2)} = \frac{y(-1-2x-2x^3y^2)}{x(1-x-x^3y^2)}.$$

$$39. g(x) = x \sin^{-1}\left(\frac{x}{4}\right) + \sqrt{16-x^2} \Rightarrow g'(x) = \sin^{-1}\left(\frac{x}{4}\right) + \frac{x}{4\sqrt{1-(x/4)^2}} - \frac{x}{\sqrt{16-x^2}} = \sin^{-1}\left(\frac{x}{4}\right) \Rightarrow$$

$$g'(2) = \sin^{-1} \frac{1}{2} = \frac{\pi}{6}$$

$$40. y = 3 \arccos \frac{x}{2} \Rightarrow y' = 3 \left[-\frac{1}{\sqrt{1-(x/2)^2}} \right] \left(\frac{1}{2} \right), \text{ so at } (1, \pi), y' = -\frac{3}{2\sqrt{1-\frac{1}{4}}} = -\sqrt{3}. \text{ An equation of}$$

the tangent line is $y - \pi = -\sqrt{3}(x - 1)$, or $y = -\sqrt{3}x + \pi + \sqrt{3}$.

$$41. f(x) = e^{-x} \arctan x \Rightarrow$$

$$f'(x) = \frac{e^{-x}}{1+x^2} - e^{-x} \arctan x. \text{ The answer is reasonable}$$

since f' is positive where f is increasing and f' is negative where f is decreasing.

$$42. f(x) = x \arcsin(1-x^2) \Rightarrow$$

$$f'(x) = x \left[\frac{-2x}{\sqrt{1-(1-x^2)^2}} \right] + \arcsin(1-x^2) \cdot 1$$

$$= \arcsin(1-x^2) - \frac{2x^2}{\sqrt{2x^2-x^4}}$$

This is reasonable because the graphs show that f is increasing when f' is positive, and that f has an inflection point when f' changes from increasing to decreasing.

$$43. \lim_{x \rightarrow -1^+} \sin^{-1} x = \sin^{-1}(-1) = -\frac{\pi}{2}$$

$$44. \text{ Let } t = \frac{1+x^2}{1+2x^2}. \text{ As } x \rightarrow \infty, t = \frac{1+x^2}{1+2x^2} = \frac{1/x^2+1}{1/x^2+2} \rightarrow \frac{1}{2}.$$

$$\lim_{x \rightarrow \infty} \arccos\left(\frac{1+x^2}{1+2x^2}\right) = \lim_{t \rightarrow 1/2} \arccos t = \arccos \frac{1}{2} = \frac{\pi}{3}.$$

$$45. \text{ Let } t = e^x. \text{ As } x \rightarrow \infty, t \rightarrow \infty. \lim_{x \rightarrow \infty} \arctan(e^x) = \lim_{t \rightarrow \infty} \arctan t = \frac{\pi}{2} \text{ by (8).}$$

$$46. \text{ Let } t = \ln x. \text{ As } x \rightarrow 0^+, t \rightarrow -\infty. \lim_{x \rightarrow 0^+} \tan^{-1}(\ln x) = \lim_{t \rightarrow -\infty} \tan^{-1} t = -\frac{\pi}{2} \text{ by (8).}$$

47.

From the figure, $\tan \alpha = \frac{5}{x}$ and $\tan \beta = \frac{2}{3-x}$. Since

$$\alpha + \beta + \theta = 180^\circ = \pi, \theta = \pi - \tan^{-1}\left(\frac{5}{x}\right) - \tan^{-1}\left(\frac{2}{3-x}\right) \Rightarrow$$

$$\begin{aligned} \frac{d\theta}{dx} &= -\frac{1}{1 + \left(\frac{5}{x}\right)^2} \left(-\frac{5}{x^2}\right) - \frac{1}{1 + \left(\frac{2}{3-x}\right)^2} \left[\frac{2}{(3-x)^2}\right] \\ &= \frac{x^2}{x^2 + 25} \cdot \frac{5}{x^2} - \frac{(3-x)^2}{(3-x)^2 + 4} \cdot \frac{2}{(3-x)^2}. \end{aligned}$$

$$\text{Now } \frac{d\theta}{dx} = 0 \Rightarrow \frac{5}{x^2 + 25} = \frac{2}{x^2 - 6x + 13} \Rightarrow 2x^2 + 50 = 5x^2 - 30x + 65 \Rightarrow$$

$3x^2 - 30x + 15 = 0 \Rightarrow x^2 - 10x + 5 = 0 \Rightarrow x = 5 \pm 2\sqrt{5}$. We reject the root with the + sign, since it is larger than 3. $d\theta/dx > 0$ for $x < 5 - 2\sqrt{5}$ and $d\theta/dx < 0$ for $x > 5 - 2\sqrt{5}$, so θ is maximized when $|AP| = x = 5 - 2\sqrt{5} \approx 0.53$.

48. Let x be the distance from the observer to the wall. Then, from the given figure,

$$\theta = \tan^{-1}\left(\frac{h+d}{x}\right) - \tan^{-1}\left(\frac{d}{x}\right), x > 0 \Rightarrow$$

$$\begin{aligned} \frac{d\theta}{dx} &= \frac{1}{1 + [(h+d)/x]^2} \left[-\frac{h+d}{x^2}\right] - \frac{1}{1 + (d/x)^2} \left[-\frac{d}{x^2}\right] = -\frac{h+d}{x^2 + (h+d)^2} + \frac{d}{x^2 + d^2} \\ &= \frac{d[x^2 + (h+d)^2] - (h+d)(x^2 + d^2)}{[x^2 + (h+d)^2](x^2 + d^2)} = \frac{h^2d + hd^2 - hx^2}{[x^2 + (h+d)^2](x^2 + d^2)} = 0 \Leftrightarrow \end{aligned}$$

$hx^2 = h^2d + hd^2 \Leftrightarrow x^2 = hd + d^2 \Leftrightarrow x = \sqrt{d(h+d)}$. Since $d\theta/dx > 0$ for all $x < \sqrt{d(h+d)}$ and $d\theta/dx < 0$ for all $x > \sqrt{d(h+d)}$, the absolute maximum occurs when $x = \sqrt{d(h+d)}$.

49.

$$\frac{dx}{dt} = 2 \text{ ft/s}, \sin \theta = \frac{x}{10} \Rightarrow \theta = \sin^{-1}\left(\frac{x}{10}\right), \frac{d\theta}{dx} = \frac{1/10}{\sqrt{1 - (x/10)^2}},$$

$$\frac{d\theta}{dt} = \frac{d\theta}{dx} \frac{dx}{dt} = \frac{1/10}{\sqrt{1 - (x/10)^2}} (2) \text{ rad/s},$$

$$\left. \frac{d\theta}{dt} \right|_{x=6} = \frac{2/10}{\sqrt{1 - (6/10)^2}} \text{ rad/s} = \frac{1}{4} \text{ rad/s}$$

50.

$$\frac{d\theta}{dt} = 4 \text{ rev/min} = 8\pi \cdot 60 \text{ rad/h. From the diagram, we see that } \tan \theta = \frac{x}{3}$$

$$\Rightarrow \theta = \tan^{-1}\left(\frac{x}{3}\right). \text{ Thus, } 8\pi \cdot 60 = \frac{d\theta}{dt} = \frac{d\theta}{dx} \frac{dx}{dt} = \frac{1/3}{1 + (x/3)^2} \frac{dx}{dt}.$$

$$\text{So } \frac{dx}{dt} = 8\pi \cdot 60 \cdot 3 \left[1 + \left(\frac{x}{3}\right)^2\right] \text{ km/h, and at } x = 1,$$

$$\frac{dx}{dt} = 8\pi \cdot 60 \cdot 3 \left[1 + \frac{1}{9}\right] \text{ km/h} = 1600\pi \text{ km/h.}$$

51. $y = f(x) = \sin^{-1}(x/(x+1))$ A. $D = \{x \mid -1 \leq x/(x+1) \leq 1\}$. For $x > -1$ we have

$$-x-1 \leq x \leq x+1 \Leftrightarrow 2x \geq -1 \Leftrightarrow x \geq -\frac{1}{2}, \text{ so } D = [-\frac{1}{2}, \infty).$$

B. Intercepts are 0 C. No symmetry D. $\lim_{x \rightarrow \infty} \sin^{-1}\left(\frac{x}{x+1}\right) = \lim_{x \rightarrow \infty} \sin^{-1}\left(\frac{1}{1+1/x}\right) = \sin^{-1} 1 = \frac{\pi}{2}$, so $y = \frac{\pi}{2}$ is a HA.

$$\text{E. } f'(x) = \frac{1}{\sqrt{1 - [x/(x+1)]^2}} \cdot \frac{(x+1) - x}{(x+1)^2} = \frac{1}{(x+1)\sqrt{2x+1}} > 0,$$

so f is increasing on $(-\frac{1}{2}, \infty)$. F. No local maximum or minimum,

$$f(-\frac{1}{2}) = \sin^{-1}(-1) = -\frac{\pi}{2} \text{ is an absolute minimum}$$

$$\begin{aligned} \text{G. } f''(x) &= -\frac{\sqrt{2x+1} + (x+1)/\sqrt{2x+1}}{(x+1)^2(2x+1)} \\ &= -\frac{3x+2}{(x+1)^2(2x+1)^{3/2}} < 0 \text{ on } D, \text{ so } f \text{ is CD on } (-\frac{1}{2}, \infty). \end{aligned}$$

52. $y = f(x) = \tan^{-1}\left(\frac{x-1}{x+1}\right)$ A. $D = \{x \mid x \neq -1\}$

B. x -intercept = 1, y -intercept = $f(0) = \tan^{-1}(-1) = -\frac{\pi}{4}$ C. No symmetry

D. $\lim_{x \rightarrow \pm\infty} \tan^{-1}\left(\frac{x-1}{x+1}\right) = \lim_{x \rightarrow \pm\infty} \tan^{-1}\left(\frac{1-1/x}{1+1/x}\right) = \tan^{-1} 1 = \frac{\pi}{4}$, so $y = \frac{\pi}{4}$ is a HA. Also

$$\lim_{x \rightarrow -1^+} \tan^{-1}\left(\frac{x-1}{x+1}\right) = -\frac{\pi}{2} \text{ and } \lim_{x \rightarrow -1^-} \tan^{-1}\left(\frac{x-1}{x+1}\right) = \frac{\pi}{2}.$$

$$\begin{aligned} \text{E. } f'(x) &= \frac{1}{1 + [(x-1)/(x+1)]^2} \cdot \frac{(x+1) - (x-1)}{(x+1)^2} \\ &= \frac{2}{(x+1)^2 + (x-1)^2} = \frac{1}{x^2 + 1} > 0 \end{aligned}$$

so f is increasing on $(-\infty, -1)$ and $(-1, \infty)$. F. No extreme values

G. $f''(x) = -2x/(x^2 + 1)^2 > 0 \Leftrightarrow x < 0$, so f is CU on $(-\infty, -1)$ and $(-1, 0)$, and CD on $(0, \infty)$.

IP at $(0, -\frac{\pi}{4})$

53. $y = f(x) = x - \tan^{-1} x$ A. $D = \mathbb{R}$ B. Intercepts are 0 C. $f(-x) = -f(x)$, so the curve is symmetric about the origin. D. $\lim_{x \rightarrow \infty} (x - \tan^{-1} x) = \infty$ and $\lim_{x \rightarrow -\infty} (x - \tan^{-1} x) = -\infty$, no HA.

But $f(x) - (x - \frac{\pi}{2}) = -\tan^{-1} x + \frac{\pi}{2} \rightarrow 0$ as $x \rightarrow \infty$, and

$f(x) - (x + \frac{\pi}{2}) = -\tan^{-1} x - \frac{\pi}{2} \rightarrow 0$ as $x \rightarrow -\infty$, so $y = x \pm \frac{\pi}{2}$ are

slant asymptotes. E. $f'(x) = 1 - \frac{1}{x^2 + 1} = \frac{x^2}{x^2 + 1} > 0$, so f is

increasing on $\mathbb{R}$. F. No extrema

$$\text{G. } f''(x) = \frac{(1+x^2)(2x) - x^2(2x)}{(1+x^2)^2} = \frac{2x}{(1+x^2)^2} > 0 \Leftrightarrow x > 0, \text{ so}$$

f is CU on $(0, \infty)$, CD on $(-\infty, 0)$. IP at $(0, 0)$.

54. $y = \tan^{-1}(\ln x)$ A. $D = (0, \infty)$ B. No y -intercept, x -intercept when $\tan^{-1}(\ln x) = 0 \Leftrightarrow \ln x = 0$

$$\Leftrightarrow x = 1. \text{ C. No symmetry D. } \lim_{x \rightarrow \infty} \tan^{-1}(\ln x) = \frac{\pi}{2},$$

so $y = \frac{\pi}{2}$ is a HA. Also $\lim_{x \rightarrow 0^+} \tan^{-1}(\ln x) = -\frac{\pi}{2}$.

$$\text{E. } f'(x) = \frac{1}{x[1 + (\ln x)^2]} > 0, \text{ so } f \text{ is increasing on } (0, \infty).$$

F. No maximum or minimum

$$\text{G. } f''(x) = \frac{-[1 + (\ln x)^2 + x(2 \ln x/x)]}{x^2[1 + (\ln x)^2]^2} = -\frac{(1 + \ln x)^2}{x^2[1 + (\ln x)^2]^2} < 0,$$

so f is CD on $(0, \infty)$.

55. $f(x) = \arctan(\cos(3 \arcsin x))$. We use a CAS to compute f' and f'' , and to graph f , f' , and f'' :

From the graph of f' , it appears that the only maximum occurs at $x = 0$ and there are minima at $x = \pm 0.87$. From the graph of f'' , it appears that there are inflection points at $x = \pm 0.52$.

56. First note that the function $f(x) = x - c \sin^{-1} x$ is only defined on the interval $[-1, 1]$, since $\sin^{-1}$ is only defined on that interval. We differentiate to get $f'(x) = 1 - c/\sqrt{1-x^2}$. Now if $c \leq 0$, then $f'(x) \geq 1$, so there is no

extremum and f is increasing on its domain. If $c > 1$, then $f'(x) < 0$, so there is no local extremum and f is decreasing on its domain, and if $c = 1$, then there is still no extremum, since $f'(x)$ does not change sign at $x = 0$. So we can only have local extrema if $0 < c < 1$. In this case, f is increasing where $f'(x) > 0 \Leftrightarrow \sqrt{1-x^2} > c \Leftrightarrow |x| < \sqrt{1-c^2}$, and decreasing where $\sqrt{1-c^2} < |x| \leq 1$. f has a maximum at $x = \sqrt{1-c^2}$ and a minimum at $x = -\sqrt{1-c^2}$.

57. $f(x) = 2x + 5(1-x^2)^{-1/2} = 2x + 5/\sqrt{1-x^2} \Rightarrow F(x) = x^2 + 5 \sin^{-1} x + C$

58. $f'(x) = 4 - 3(1+x^2)^{-1} \Rightarrow f(x) = 4x - 3 \tan^{-1} x + C \Rightarrow f(\frac{\pi}{4}) = \pi - 3 + C = 0 \Rightarrow C = 3 - \pi$,
so $f(x) = 4x - 3 \tan^{-1} x + 3 - \pi$.

59. $\int_{1/2}^{\sqrt{3}/2} \frac{6}{\sqrt{1-t^2}} dt = 6 \int_{1/2}^{\sqrt{3}/2} \frac{1}{\sqrt{1-t^2}} dt = 6 [\sin^{-1} t]_{1/2}^{\sqrt{3}/2} = 6 \left[\sin^{-1} \left(\frac{\sqrt{3}}{2} \right) - \sin^{-1} \left(\frac{1}{2} \right) \right]$
 $= 6 \left(\frac{\pi}{3} - \frac{\pi}{6} \right) = 6 \left(\frac{\pi}{6} \right) = \pi$

60. $\int_0^1 \frac{4}{t^2+1} dt = 4 \int_0^1 \frac{1}{1+t^2} dt = 4 [\tan^{-1} t]_0^1 = 4 (\tan^{-1} 1 - \tan^{-1} 0) = 4 \left(\frac{\pi}{4} - 0 \right) = \pi$

61. Let $u = 4x$. Then $du = 4 dx$, so

$$\int_0^{\sqrt{3}/4} \frac{dx}{1+16x^2} = \frac{1}{4} \int_0^{\sqrt{3}} \frac{1}{1+u^2} du = \frac{1}{4} [\tan^{-1} u]_0^{\sqrt{3}} = \frac{1}{4} (\tan^{-1} \sqrt{3} - \tan^{-1} 0) = \frac{1}{4} \left(\frac{\pi}{3} - 0 \right) = \frac{\pi}{12}.$$

62. Let $u = 2t$. Then $\sqrt{1-4t^2} = \sqrt{1-u^2}$ and $du = 2 dt$, so

$$\int \frac{dt}{\sqrt{1-4t^2}} = \int \frac{\frac{1}{2} du}{\sqrt{1-u^2}} = \frac{1}{2} \sin^{-1} u + C = \frac{1}{2} \sin^{-1} (2t) + C.$$

63. Let $u = \sin^{-1} x$. Then $du = \frac{1}{\sqrt{1-x^2}} dx$, so $\int_0^{1/2} \frac{\sin^{-1} x}{\sqrt{1-x^2}} dx = \int_0^{\pi/6} u du = \left[\frac{u^2}{2} \right]_0^{\pi/6} = \frac{1}{2} \left(\frac{\pi}{6} \right)^2 = \frac{\pi^2}{72}$.

64. Let $u = -\cos x$. Then $du = \sin x dx$, so

$$\int_0^{\pi/2} \frac{\sin x}{1+\cos^2 x} dx = \int_{-1}^0 \frac{1}{1+u^2} du = [\tan^{-1} u]_{-1}^0 = \tan^{-1} 0 - \tan^{-1} (-1) = 0 - \left(-\frac{\pi}{4} \right) = \frac{\pi}{4}.$$

65. $\int \frac{x+9}{x^2+9} dx = \int \frac{x}{x^2+9} dx + 9 \int \frac{1}{x^2+9} dx = \frac{1}{2} \ln(x^2+9) + 3 \tan^{-1} \frac{x}{3} + C$

(Let $u = x^2 + 9$ in the first integral; use Equation 14 in the second.)

66. Let $u = \tan^{-1} x$. Then $du = dx/(1+x^2)$, so $\int \frac{\tan^{-1} x}{1+x^2} dx = \int u du = \frac{1}{2}u^2 + C = \frac{1}{2}(\tan^{-1} x)^2 + C$.

67. Let $u = t^3$. Then $du = 3t^2 dt$ and $\int \frac{t^2}{\sqrt{1-t^6}} dt = \int \frac{\frac{1}{3} du}{\sqrt{1-u^2}} = \frac{1}{3} \sin^{-1} u + C = \frac{1}{3} \sin^{-1}(t^3) + C$.

68. Let $u = \frac{1}{2}x$. Then $du = \frac{1}{2} dx \Rightarrow$

$$\begin{aligned} \int \frac{dx}{x\sqrt{x^2-4}} &= \int \frac{dx}{2x\sqrt{(x/2)^2-1}} = \int \frac{2 du}{4u\sqrt{u^2-1}} = \frac{1}{2} \int \frac{du}{u\sqrt{u^2-1}} \\ &= \frac{1}{2} \sec^{-1} u + C = \frac{1}{2} \sec^{-1}\left(\frac{1}{2}x\right) + C \end{aligned}$$

69. Let $u = \sqrt{x}$. Then $du = \frac{dx}{2\sqrt{x}}$ and $\int \frac{dx}{\sqrt{x}(1+x)} = \int \frac{2 du}{1+u^2} = 2 \tan^{-1} u + C = 2 \tan^{-1} \sqrt{x} + C$.

70. Let $u = e^{2x}$. Then $du = 2e^{2x} dx \Rightarrow \int \frac{e^{2x} dx}{\sqrt{1-e^{4x}}} = \frac{1}{2} \int \frac{du}{\sqrt{1-u^2}} = \frac{1}{2} \sin^{-1} u + C = \frac{1}{2} \sin^{-1}(e^{2x}) + C$

71. Let $u = x/a$. Then $du = dx/a$, so

$$\int \frac{dx}{\sqrt{a^2-x^2}} = \int \frac{dx}{a\sqrt{1-(x/a)^2}} = \int \frac{du}{\sqrt{1-u^2}} = \sin^{-1} u + C = \sin^{-1} \frac{x}{a} + C.$$

72. We use the disk method: $A = \int_0^2 \pi \left[\frac{1}{\sqrt{x^2+4}} \right]^2 dx = \pi \int_0^2 \frac{1}{x^2+4} dx$. By Formula 14, this is equal to

$$\pi \left[\frac{1}{2} \tan^{-1}(x/2) \right]_0^2 = \frac{\pi}{2} \left(\frac{\pi}{4} - 0 \right) = \frac{\pi^2}{8}.$$

73.

The integral represents the area below the curve $y = \sin^{-1} x$ on the interval $x \in [0, 1]$. The bounding curves are $y = \sin^{-1} x \Leftrightarrow x = \sin y$, $y = 0$ and $x = 1$. We see that y ranges between $\sin^{-1} 0 = 0$ and $\sin^{-1} 1 = \frac{\pi}{2}$. So we have to integrate the function $x = 1 - \sin y$ between $y = 0$ and $y = \frac{\pi}{2}$:

$$\int_0^1 \sin^{-1} x dx = \int_0^{\pi/2} (1 - \sin y) dy = \left(\frac{\pi}{2} + \cos \frac{\pi}{2} \right) - (0 + \cos 0) = \frac{\pi}{2} - 1.$$

74. Let $a = \arctan x$ and $b = \arctan y$. Then by the addition formula for the tangent (see Reference Page 2 in the

$$\text{textbook}), \tan(a+b) = \frac{\tan a + \tan b}{1 - (\tan a)(\tan b)} = \frac{\tan(\arctan x) + \tan(\arctan y)}{1 - \tan(\arctan x) \tan(\arctan y)} \Rightarrow \tan(a+b) = \frac{x+y}{1-xy}$$

$$\Rightarrow \arctan x + \arctan y = a+b = \arctan\left(\frac{x+y}{1-xy}\right), \text{ since } -\frac{\pi}{2} < \arctan x + \arctan y < \frac{\pi}{2}.$$

75. (a) $\arctan \frac{1}{2} + \arctan \frac{1}{3} = \arctan\left(\frac{\frac{1}{2} + \frac{1}{3}}{1 - \frac{1}{2} \cdot \frac{1}{3}}\right) = \arctan 1 = \frac{\pi}{4}$

$$\begin{aligned} \text{(b) } 2 \arctan \frac{1}{3} + \arctan \frac{1}{7} &= \left(\arctan \frac{1}{3} + \arctan \frac{1}{3} \right) + \arctan \frac{1}{7} = \arctan\left(\frac{\frac{1}{3} + \frac{1}{3}}{1 - \frac{1}{3} \cdot \frac{1}{3}}\right) + \arctan \frac{1}{7} \\ &= \arctan \frac{3}{4} + \arctan \frac{1}{7} = \arctan\left(\frac{\frac{3}{4} + \frac{1}{7}}{1 - \frac{3}{4} \cdot \frac{1}{7}}\right) = \arctan 1 = \frac{\pi}{4} \end{aligned}$$

76. (a) $f(x) = \sin(\sin^{-1} x)$

(b) $g(x) = \sin^{-1}(\sin x)$

(c) $g'(x) = \frac{d}{dx} \sin^{-1}(\sin x) = \frac{1}{\sqrt{1 - \sin^2 x}} \cos x = \frac{\cos x}{\sqrt{\cos^2 x}} = \frac{\cos x}{|\cos x|}$

(d) $h(x) = \cos^{-1}(\sin x)$, so $h'(x) = -\frac{\cos x}{\sqrt{1 - \sin^2 x}} = -\frac{\cos x}{|\cos x|}$

77. Let $f(x) = 2 \sin^{-1} x - \cos^{-1}(1 - 2x^2)$. Then

$$f'(x) = \frac{2}{\sqrt{1-x^2}} - \frac{4x}{\sqrt{1-(1-2x^2)^2}} = \frac{2}{\sqrt{1-x^2}} - \frac{4x}{2x\sqrt{1-x^2}} = 0 \quad [\text{since } x \geq 0]$$

Thus $f'(x) = 0$ for all $x \in [0, 1]$. Thus $f(x) = C$. To find C let $x = 0$. Thus $2 \sin^{-1}(0) - \cos^{-1}(1) = 0 = C$.

Therefore we see that $f(x) = 2 \sin^{-1} x - \cos^{-1}(1 - 2x^2) = 0 \Rightarrow 2 \sin^{-1} x = \cos^{-1}(1 - 2x^2)$.

78. Let $f(x) = \sin^{-1}\left(\frac{x-1}{x+1}\right) - 2 \tan^{-1} \sqrt{x} + \frac{\pi}{2}$. Note that the domain of f is $[0, \infty)$. Thus

$$f'(x) = \frac{1}{\sqrt{1 - \left(\frac{x-1}{x+1}\right)^2}} \cdot \frac{(x+1) - (x-1)}{(x+1)^2} - \frac{2}{1+x} \cdot \frac{1}{2\sqrt{x}} = \frac{1}{\sqrt{x}(x+1)} - \frac{1}{\sqrt{x}(x+1)} = 0$$

Then $f(x) = C$. To find C , we let $x = 0 \Rightarrow \sin^{-1}(-1) - 2 \tan^{-1}(0) + \frac{\pi}{2} = C \Rightarrow -\frac{\pi}{2} - 0 + \frac{\pi}{2} = 0 = C$.

Thus, $f(x) = 0 \Rightarrow \sin^{-1}\left(\frac{x-1}{x+1}\right) = 2 \tan^{-1} \sqrt{x} - \frac{\pi}{2}$.

79. $y = \sec^{-1} x \Rightarrow \sec y = x \Rightarrow \sec y \tan y \frac{dy}{dx} = 1 \Rightarrow \frac{dy}{dx} = \frac{1}{\sec y \tan y}$. Now

$\tan^2 y = \sec^2 y - 1 = x^2 - 1$, so $\tan y = \pm \sqrt{x^2 - 1}$. For $y \in [0, \frac{\pi}{2})$, $x \geq 1$, so $\sec y = x = |x|$ and $\tan y \geq 0$

$\Rightarrow \frac{dy}{dx} = \frac{1}{x\sqrt{x^2-1}} = \frac{1}{|x|\sqrt{x^2-1}}$. For $y \in (\frac{\pi}{2}, \pi]$, $x \leq -1$, so $|x| = -x$ and $\tan y = -\sqrt{x^2-1} \Rightarrow$

$$\frac{dy}{dx} = \frac{1}{\sec y \tan y} = \frac{1}{x(-\sqrt{x^2-1})} = \frac{1}{(-x)\sqrt{x^2-1}} = \frac{1}{|x|\sqrt{x^2-1}}$$

- 80.** (a) Since $|\arctan(1/x)| < \frac{\pi}{2}$, we have $0 \leq |x \arctan(1/x)| \leq \frac{\pi}{2} |x| \rightarrow 0$ as $x \rightarrow 0$. So, by the Squeeze Theorem,

$\lim_{x \rightarrow 0} f(x) = 0 = f(0)$, so f is continuous at 0.

- (b) Here $\frac{f(x) - f(0)}{x - 0} = \frac{x \arctan(1/x) - 0}{x} = \arctan\left(\frac{1}{x}\right)$. So (see Exercise 44 in

Section 3.2 for a discussion of left- and right-hand derivatives)

$$f'_-(0) = \lim_{x \rightarrow 0^-} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0^-} \arctan\left(\frac{1}{x}\right) = \lim_{y \rightarrow -\infty} \arctan y = -\frac{\pi}{2}, \text{ while}$$

$$f'_+(0) = \lim_{x \rightarrow 0^+} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0^+} \arctan\left(\frac{1}{x}\right) = \lim_{y \rightarrow \infty} \arctan y = \frac{\pi}{2}. \text{ So } f'(0) \text{ does not exist.}$$

APPLIED PROJECT Where to Sit at the Movies

1.

$|VP| = 9 + x \cos \alpha$, $|PT| = 35 - (4 + x \sin \alpha) = 31 - x \sin \alpha$, and

$|PB| = (4 + x \sin \alpha) - 10 = x \sin \alpha - 6$. So using the Pythagorean Theorem, we have

$$|VT| = \sqrt{|VP|^2 + |PT|^2} = \sqrt{(9 + x \cos \alpha)^2 + (31 - x \sin \alpha)^2} = a, \text{ and}$$

$|VB| = \sqrt{|VP|^2 + |PB|^2} = \sqrt{(9 + x \cos \alpha)^2 + (x \sin \alpha - 6)^2} = b$. Using the Law of Cosines on $\triangle VBT$, we

$$\text{get } 25^2 = a^2 + b^2 - 2ab \cos \theta \Leftrightarrow \cos \theta = \frac{a^2 + b^2 - 625}{2ab} \Leftrightarrow \theta = \arccos\left(\frac{a^2 + b^2 - 625}{2ab}\right), \text{ as required.}$$

2. From the graph of θ , it appears that the value of x which maximizes θ is $x \approx 8.25$ ft. Assuming that the first row is at $x = 0$, the row closest to this value of x is the fourth row, at $x = 9$ ft, and from the graph, the viewing angle in this row seems to be about 0.85 radians, or about 49° .

3. With a CAS, we type in the definition of θ , substitute in the proper values of a and b in terms of x and $\alpha = 20^\circ = \frac{\pi}{9}$ radians, and then use the differentiation command to find the derivative. We use a numerical root finder and find that the root of the equation $d\theta/dx = 0$ is $x \approx 8.253062$, as approximated in Problem 2.
4. From the graph in Problem 2, it seems that the average value of the function on the interval $[0, 60]$ is about 0.6. We can use a CAS to approximate $\frac{1}{60} \int_0^{60} \theta(x) dx \approx 0.625 \approx 36^\circ$. (The calculation is much faster if we reduce the number of digits of accuracy required.) The minimum value is $\theta(60) \approx 0.38$ and, from Problem 2, the maximum value is about 0.85.

7.6 Hyperbolic Functions

1. (a) $\sinh 0 = \frac{1}{2}(e^0 - e^0) = 0$ (b) $\cosh 0 = \frac{1}{2}(e^0 + e^0) = \frac{1}{2}(1 + 1) = 1$
2. (a) $\tanh 0 = \frac{(e^0 - e^{-0})/2}{(e^0 + e^{-0})/2} = 0$ (b) $\tanh 1 = \frac{e^1 - e^{-1}}{e^1 + e^{-1}} = \frac{e^2 - 1}{e^2 + 1} \approx 0.76159$
3. (a) $\sinh(\ln 2) = \frac{e^{\ln 2} - e^{-\ln 2}}{2} = \frac{e^{\ln 2} - (e^{\ln 2})^{-1}}{2} = \frac{2 - 2^{-1}}{2} = \frac{2 - \frac{1}{2}}{2} = \frac{3}{4}$
(b) $\sinh 2 = \frac{1}{2}(e^2 - e^{-2}) \approx 3.62686$
4. (a) $\cosh 3 = \frac{1}{2}(e^3 + e^{-3}) \approx 10.06766$ (b) $\cosh(\ln 3) = \frac{e^{\ln 3} + e^{-\ln 3}}{2} = \frac{3 + \frac{1}{3}}{2} = \frac{5}{3}$
5. (a) $\operatorname{sech} 0 = \frac{1}{\cosh 0} = \frac{1}{1} = 1$ (b) $\cosh^{-1} 1 = 0$ because $\cosh 0 = 1$.
6. (a) $\sinh 1 = \frac{1}{2}(e^1 - e^{-1}) \approx 1.17520$
(b) Using Equation 3, we have $\sinh^{-1} 1 = \ln(1 + \sqrt{1^2 + 1}) = \ln(1 + \sqrt{2}) \approx 0.88137$.
7. $\sinh(-x) = \frac{1}{2}[e^{-x} - e^{-(-x)}] = \frac{1}{2}(e^{-x} - e^x) = -\frac{1}{2}(e^x - e^{-x}) = -\sinh x$
8. $\cosh(-x) = \frac{1}{2}[e^{-x} + e^{-(-x)}] = \frac{1}{2}(e^{-x} + e^x) = \frac{1}{2}(e^x + e^{-x}) = \cosh x$
9. $\cosh x + \sinh x = \frac{1}{2}(e^x + e^{-x}) + \frac{1}{2}(e^x - e^{-x}) = \frac{1}{2}(2e^x) = e^x$
10. $\cosh x - \sinh x = \frac{1}{2}(e^x + e^{-x}) - \frac{1}{2}(e^x - e^{-x}) = \frac{1}{2}(2e^{-x}) = e^{-x}$
11. $\sinh x \cosh y + \cosh x \sinh y = \left[\frac{1}{2}(e^x - e^{-x})\right]\left[\frac{1}{2}(e^y + e^{-y})\right] + \left[\frac{1}{2}(e^x + e^{-x})\right]\left[\frac{1}{2}(e^y - e^{-y})\right]$
 $= \frac{1}{4}[(e^{x+y} + e^{x-y} - e^{-x+y} - e^{-x-y}) + (e^{x+y} - e^{x-y} + e^{-x+y} - e^{-x-y})]$
 $= \frac{1}{4}(2e^{x+y} - 2e^{-x-y}) = \frac{1}{2}[e^{x+y} - e^{-(x+y)}] = \sinh(x+y)$

$$\begin{aligned} 12. \cosh x \cosh y + \sinh x \sinh y &= \left[\frac{1}{2}(e^x + e^{-x}) \right] \left[\frac{1}{2}(e^y + e^{-y}) \right] + \left[\frac{1}{2}(e^x - e^{-x}) \right] \left[\frac{1}{2}(e^y - e^{-y}) \right] \\ &= \frac{1}{4} [(e^{x+y} + e^{x-y} + e^{-x+y} + e^{-x-y}) + (e^{x+y} - e^{x-y} - e^{-x+y} + e^{-x-y})] \\ &= \frac{1}{4} (2e^{x+y} + 2e^{-x-y}) = \frac{1}{2} [e^{x+y} + e^{-(x+y)}] = \cosh(x+y) \end{aligned}$$

13. Divide both sides of the identity $\cosh^2 x - \sinh^2 x = 1$ by $\sinh^2 x$:

$$\frac{\cosh^2 x}{\sinh^2 x} - \frac{\sinh^2 x}{\sinh^2 x} = \frac{1}{\sinh^2 x} \Leftrightarrow \coth^2 x - 1 = \operatorname{csch}^2 x.$$

$$\begin{aligned} 14. \tanh(x+y) &= \frac{\sinh(x+y)}{\cosh(x+y)} = \frac{\sinh x \cosh y + \cosh x \sinh y}{\cosh x \cosh y + \sinh x \sinh y} = \frac{\frac{\sinh x \cosh y}{\cosh x \cosh y} + \frac{\cosh x \sinh y}{\cosh x \cosh y}}{\frac{\cosh x \cosh y}{\cosh x \cosh y} + \frac{\sinh x \sinh y}{\cosh x \cosh y}} \\ &= \frac{\tanh x + \tanh y}{1 + \tanh x \tanh y} \end{aligned}$$

15. Putting $y = x$ in the result from Exercise 11, we have

$$\sinh 2x = \sinh(x+x) = \sinh x \cosh x + \cosh x \sinh x = 2 \sinh x \cosh x.$$

16. Putting $y = x$ in the result from Exercise 12, we have

$$\cosh 2x = \cosh(x+x) = \cosh x \cosh x + \sinh x \sinh x = \cosh^2 x + \sinh^2 x.$$

$$\begin{aligned} 17. \tanh(\ln x) &= \frac{\sinh(\ln x)}{\cosh(\ln x)} = \frac{(e^{\ln x} - e^{-\ln x})/2}{(e^{\ln x} + e^{-\ln x})/2} = \frac{x - (e^{\ln x})^{-1}}{x + (e^{\ln x})^{-1}} = \frac{x - x^{-1}}{x + x^{-1}} \\ &= \frac{x - 1/x}{x + 1/x} = \frac{(x^2 - 1)/x}{(x^2 + 1)/x} = \frac{x^2 - 1}{x^2 + 1} \end{aligned}$$

$$\begin{aligned} 18. \frac{1 + \tanh x}{1 - \tanh x} &= \frac{1 + (\sinh x)/\cosh x}{1 - (\sinh x)/\cosh x} = \frac{\cosh x + \sinh x}{\cosh x - \sinh x} = \frac{\frac{1}{2}(e^x + e^{-x}) + \frac{1}{2}(e^x - e^{-x})}{\frac{1}{2}(e^x + e^{-x}) - \frac{1}{2}(e^x - e^{-x})} \\ &= \frac{e^x + e^{-x} + e^x - e^{-x}}{e^x + e^{-x} - e^x + e^{-x}} = \frac{2e^x}{2e^{-x}} = e^{2x} \end{aligned}$$

$$\text{Or: Using the results of Exercises 9 and 10, } \frac{\cosh x + \sinh x}{\cosh x - \sinh x} = \frac{e^x}{e^{-x}} = e^{2x}$$

19. By Exercise 9, $(\cosh x + \sinh x)^n = (e^x)^n = e^{nx} = \cosh nx + \sinh nx$.

20. $\sinh x = \frac{3}{4} \Rightarrow \operatorname{csch} x = 1/\sinh x = \frac{4}{3}$, $\cosh^2 x = \sinh^2 x + 1 = \frac{9}{16} + 1 = \frac{25}{16} \Rightarrow \cosh x = \frac{5}{4}$ (since $\cosh x > 0$), $\operatorname{sech} x = 1/\cosh x = \frac{4}{5}$, $\tanh x = \sinh x/\cosh x = \frac{3/4}{5/4} = \frac{3}{5}$, and $\coth x = 1/\tanh x = \frac{5}{3}$.

21. $\tanh x = \frac{4}{5} > 0$, so $x > 0$. $\coth x = 1/\tanh x = \frac{5}{4}$, $\operatorname{sech}^2 x = 1 - \tanh^2 x = 1 - \left(\frac{4}{5}\right)^2 = \frac{9}{25} \Rightarrow \operatorname{sech} x = \frac{3}{5}$ (since $\operatorname{sech} x > 0$), $\cosh x = 1/\operatorname{sech} x = \frac{5}{3}$, $\sinh x = \tanh x \cosh x = \frac{4}{5} \cdot \frac{5}{3} = \frac{4}{3}$, and $\operatorname{csch} x = 1/\sinh x = \frac{3}{4}$.

22.

$$23. (a) \lim_{x \rightarrow \infty} \tanh x = \lim_{x \rightarrow \infty} \frac{e^x - e^{-x}}{e^x + e^{-x}} \cdot \frac{e^{-x}}{e^{-x}} = \lim_{x \rightarrow \infty} \frac{1 - e^{-2x}}{1 + e^{-2x}} = \frac{1 - 0}{1 + 0} = 1$$

$$(b) \lim_{x \rightarrow -\infty} \tanh x = \lim_{x \rightarrow -\infty} \frac{e^x - e^{-x}}{e^x + e^{-x}} \cdot \frac{e^x}{e^x} = \lim_{x \rightarrow -\infty} \frac{e^{2x} - 1}{e^{2x} + 1} = \frac{0 - 1}{0 + 1} = -1$$

$$(c) \lim_{x \rightarrow \infty} \sinh x = \lim_{x \rightarrow \infty} \frac{e^x - e^{-x}}{2} = \infty$$

$$(d) \lim_{x \rightarrow -\infty} \sinh x = \lim_{x \rightarrow -\infty} \frac{e^x - e^{-x}}{2} = -\infty$$

$$(e) \lim_{x \rightarrow \infty} \operatorname{sech} x = \lim_{x \rightarrow \infty} \frac{2}{e^x + e^{-x}} = 0$$

$$(f) \lim_{x \rightarrow \infty} \operatorname{coth} x = \lim_{x \rightarrow \infty} \frac{e^x + e^{-x}}{e^x - e^{-x}} \cdot \frac{e^{-x}}{e^{-x}} = \lim_{x \rightarrow \infty} \frac{1 + e^{-2x}}{1 - e^{-2x}} = \frac{1 + 0}{1 - 0} = 1 \quad [\text{Or: Use part (a)}]$$

$$(g) \lim_{x \rightarrow 0^+} \operatorname{coth} x = \lim_{x \rightarrow 0^+} \frac{\cosh x}{\sinh x} = \infty, \text{ since } \sinh x \rightarrow 0 \text{ through positive values and } \cosh x \rightarrow 1.$$

$$(h) \lim_{x \rightarrow 0^-} \operatorname{coth} x = \lim_{x \rightarrow 0^-} \frac{\cosh x}{\sinh x} = -\infty, \text{ since } \sinh x \rightarrow 0 \text{ through negative values and } \cosh x \rightarrow 1.$$

$$(i) \lim_{x \rightarrow -\infty} \operatorname{csch} x = \lim_{x \rightarrow -\infty} \frac{2}{e^x - e^{-x}} = 0$$

$$24. (a) \frac{d}{dx} \cosh x = \frac{d}{dx} \left[\frac{1}{2}(e^x + e^{-x}) \right] = \frac{1}{2}(e^x - e^{-x}) = \sinh x$$

$$(b) \frac{d}{dx} \tanh x = \frac{d}{dx} \left[\frac{\sinh x}{\cosh x} \right] = \frac{\cosh x \cosh x - \sinh x \sinh x}{\cosh^2 x} = \frac{\cosh^2 x - \sinh^2 x}{\cosh^2 x} = \frac{1}{\cosh^2 x} = \operatorname{sech}^2 x$$

$$(c) \frac{d}{dx} \operatorname{csch} x = \frac{d}{dx} \left[\frac{1}{\sinh x} \right] = -\frac{\cosh x}{\sinh^2 x} = -\frac{1}{\sinh x} \cdot \frac{\cosh x}{\sinh x} = -\operatorname{csch} x \coth x$$

$$(d) \frac{d}{dx} \operatorname{sech} x = \frac{d}{dx} \left[\frac{1}{\cosh x} \right] = -\frac{\sinh x}{\cosh^2 x} = -\frac{1}{\cosh x} \cdot \frac{\sinh x}{\cosh x} = -\operatorname{sech} x \tanh x$$

$$(e) \frac{d}{dx} \operatorname{coth} x = \frac{d}{dx} \left[\frac{\cosh x}{\sinh x} \right] = \frac{\sinh x \sinh x - \cosh x \cosh x}{\sinh^2 x} = \frac{\sinh^2 x - \cosh^2 x}{\sinh^2 x} = -\frac{1}{\sinh^2 x} \\ = -\operatorname{csch}^2 x$$

$$25. \text{ Let } y = \sinh^{-1} x. \text{ Then } \sinh y = x \text{ and, by Example 1(a), } \cosh^2 y - \sinh^2 y = 1 \Rightarrow [\text{with } \cosh y > 0]$$

$$\cosh y = \sqrt{1 + \sinh^2 y} = \sqrt{1 + x^2}. \text{ So by Exercise 9, } e^y = \sinh y + \cosh y = x + \sqrt{1 + x^2} \Rightarrow$$

$$y = \ln(x + \sqrt{1 + x^2}).$$

26. Let $y = \cosh^{-1} x$. Then $\cosh y = x$ and $y \geq 0$, so $\sinh y = \sqrt{\cosh^2 y - 1} = \sqrt{x^2 - 1}$. So, by Exercise 9,
 $e^y = \cosh y + \sinh y = x + \sqrt{x^2 - 1} \Rightarrow y = \ln(x + \sqrt{x^2 - 1})$.

Another method: Write $x = \cosh y = \frac{1}{2}(e^y + e^{-y})$ and solve a quadratic, as in Example 3.

27. (a) Let $y = \tanh^{-1} x$. Then $x = \tanh y = \frac{\sinh y}{\cosh y} = \frac{(e^y - e^{-y})/2}{(e^y + e^{-y})/2} \cdot \frac{e^y}{e^y} = \frac{e^{2y} - 1}{e^{2y} + 1} \Rightarrow$
 $xe^{2y} + x = e^{2y} - 1 \Rightarrow 1 + x = e^{2y} - xe^{2y} \Rightarrow 1 + x = e^{2y}(1 - x) \Rightarrow$
 $e^{2y} = \frac{1+x}{1-x} \Rightarrow 2y = \ln\left(\frac{1+x}{1-x}\right) \Rightarrow y = \frac{1}{2} \ln\left(\frac{1+x}{1-x}\right)$.

- (b) Let $y = \tanh^{-1} x$. Then $x = \tanh y$, so from Exercise 18 we have

$$e^{2y} = \frac{1 + \tanh y}{1 - \tanh y} = \frac{1+x}{1-x} \Rightarrow 2y = \ln\left(\frac{1+x}{1-x}\right) \Rightarrow y = \frac{1}{2} \ln\left(\frac{1+x}{1-x}\right)$$

28. (a) (i) $y = \operatorname{csch}^{-1} x \Leftrightarrow \operatorname{csch} y = x \quad (x \neq 0)$

- (ii) We sketch the graph of csch^{-1} by reflecting the graph of csch (see Exercise 22) about the line $y = x$.

(iii) Let $y = \operatorname{csch}^{-1} x$. Then $x = \operatorname{csch} y = \frac{2}{e^y - e^{-y}} \Rightarrow xe^y - xe^{-y} = 2$
 $\Rightarrow x(e^y)^2 - 2e^y - x = 0 \Rightarrow e^y = \frac{1 \pm \sqrt{x^2 + 1}}{x}$.

But $e^y > 0$, so for $x > 0$, $e^y = \frac{1 + \sqrt{x^2 + 1}}{x}$ and for $x < 0$, $e^y = \frac{1 - \sqrt{x^2 + 1}}{x}$.

Thus, $\operatorname{csch}^{-1} x = \ln\left(\frac{1}{x} + \frac{\sqrt{x^2 + 1}}{|x|}\right)$.

- (b) (i) $y = \operatorname{sech}^{-1} x \Leftrightarrow \operatorname{sech} y = x$ and $y > 0$.

- (ii) We sketch the graph of sech^{-1} by reflecting the graph of sech (see Exercise 22) about the line $y = x$.

(iii) Let $y = \operatorname{sech}^{-1} x$, so $x = \operatorname{sech} y = \frac{2}{e^y + e^{-y}} \Rightarrow xe^y + xe^{-y} = 2$
 $\Rightarrow x(e^y)^2 - 2e^y + x = 0 \Leftrightarrow e^y = \frac{1 \pm \sqrt{1 - x^2}}{x}$.

But $y > 0 \Rightarrow e^y > 1$. This rules out the minus sign because $\frac{1 - \sqrt{1 - x^2}}{x} > 1 \Leftrightarrow 1 - \sqrt{1 - x^2} > x$
 $\Leftrightarrow 1 - x > \sqrt{1 - x^2} \Leftrightarrow 1 - 2x + x^2 > 1 - x^2 \Leftrightarrow x^2 > x \Leftrightarrow x > 1$, but $x = \operatorname{sech} y \leq 1$. Thus,
 $e^y = \frac{1 + \sqrt{1 - x^2}}{x} \Rightarrow \operatorname{sech}^{-1} x = \ln\left(\frac{1 + \sqrt{1 - x^2}}{x}\right)$.

- (c) (i) $y = \operatorname{coth}^{-1} x \Leftrightarrow \operatorname{coth} y = x$

- (ii) We sketch the graph of coth^{-1} by reflecting the graph of coth (see Exercise 22) about the line $y = x$.

(iii) Let $y = \operatorname{coth}^{-1} x$. Then $x = \operatorname{coth} y = \frac{e^y + e^{-y}}{e^y - e^{-y}} \Rightarrow$
 $xe^y - xe^{-y} = e^y + e^{-y} \Rightarrow (x-1)e^y = (x+1)e^{-y} \Rightarrow$
 $e^{2y} = \frac{x+1}{x-1} \Rightarrow 2y = \ln\left(\frac{x+1}{x-1}\right) \Rightarrow \operatorname{coth}^{-1} x = \frac{1}{2} \ln\left(\frac{x+1}{x-1}\right)$

29. (a) Let $y = \cosh^{-1} x$. Then $\cosh y = x$ and $y \geq 0 \Rightarrow \sinh y \frac{dy}{dx} = 1 \Rightarrow$

$$\frac{dy}{dx} = \frac{1}{\sinh y} = \frac{1}{\sqrt{\cosh^2 y - 1}} = \frac{1}{\sqrt{x^2 - 1}} \quad (\text{since } \sinh y \geq 0 \text{ for } y \geq 0). \text{ Or: Use Formula 4.}$$

(b) Let $y = \tanh^{-1} x$. Then $\tanh y = x \Rightarrow \operatorname{sech}^2 y \frac{dy}{dx} = 1 \Rightarrow \frac{dy}{dx} = \frac{1}{\operatorname{sech}^2 y} = \frac{1}{1 - \tanh^2 y} = \frac{1}{1 - x^2}$.

Or: Use Formula 5.

(c) Let $y = \operatorname{csch}^{-1} x$. Then $\operatorname{csch} y = x \Rightarrow -\operatorname{csch} y \coth y \frac{dy}{dx} = 1 \Rightarrow \frac{dy}{dx} = -\frac{1}{\operatorname{csch} y \coth y}$.

By Exercise 13, $\coth y = \pm \sqrt{\operatorname{csch}^2 y + 1} = \pm \sqrt{x^2 + 1}$. If $x > 0$, then $\coth y > 0$, so $\coth y = \sqrt{x^2 + 1}$.

If $x < 0$, then $\coth y < 0$, so $\coth y = -\sqrt{x^2 + 1}$. In either case we have

$$\frac{dy}{dx} = -\frac{1}{\operatorname{csch} y \coth y} = -\frac{1}{|x| \sqrt{x^2 + 1}}.$$

(d) Let $y = \operatorname{sech}^{-1} x$. Then $\operatorname{sech} y = x \Rightarrow -\operatorname{sech} y \tanh y \frac{dy}{dx} = 1 \Rightarrow$

$$\frac{dy}{dx} = -\frac{1}{\operatorname{sech} y \tanh y} = -\frac{1}{\operatorname{sech} y \sqrt{1 - \operatorname{sech}^2 y}} = -\frac{1}{x \sqrt{1 - x^2}}. \quad (\text{Note that } y > 0 \text{ and so } \tanh y > 0.)$$

(e) Let $y = \coth^{-1} x$. Then $\coth y = x \Rightarrow -\operatorname{csch}^2 y \frac{dy}{dx} = 1 \Rightarrow$

$$\frac{dy}{dx} = -\frac{1}{\operatorname{csch}^2 y} = \frac{1}{1 - \coth^2 y} = \frac{1}{1 - x^2} \text{ by Exercise 13.}$$

30. $f(x) = \tanh 4x \Rightarrow f'(x) = 4 \operatorname{sech}^2 4x$

31. $f(x) = x \cosh x \Rightarrow f'(x) = x (\cosh x)' + (\cosh x)(x)' = x \sinh x + \cosh x$

32. $g(x) = \sinh^2 x \Rightarrow g'(x) = 2 \sinh x \cosh x$

33. $h(x) = \sinh(x^2) \Rightarrow h'(x) = \cosh(x^2) \cdot 2x = 2x \cosh(x^2)$

34. $F(x) = \sinh x \tanh x \Rightarrow F'(x) = \sinh x \operatorname{sech}^2 x + \tanh x \cosh x$

35. $G(x) = \frac{1 - \cosh x}{1 + \cosh x} \Rightarrow$

$$\begin{aligned} G'(x) &= \frac{(1 + \cosh x)(-\sinh x) - (1 - \cosh x)(\sinh x)}{(1 + \cosh x)^2} \\ &= \frac{-\sinh x - \sinh x \cosh x - \sinh x + \sinh x \cosh x}{(1 + \cosh x)^2} = \frac{-2 \sinh x}{(1 + \cosh x)^2} \end{aligned}$$

36. $f(t) = e^t \operatorname{sech} t \Rightarrow f'(t) = e^t (-\operatorname{sech} t \tanh t) + (\operatorname{sech} t) e^t = e^t \operatorname{sech} t (1 - \tanh t)$

37. $h(t) = \coth \sqrt{1+t^2} \Rightarrow h'(t) = -\operatorname{csch}^2 \sqrt{1+t^2} \cdot \frac{1}{2}(1+t^2)^{-1/2} (2t) = -\frac{t \operatorname{csch}^2 \sqrt{1+t^2}}{\sqrt{1+t^2}}$

38. $f(t) = \ln(\sinh t) \Rightarrow f'(t) = \frac{1}{\sinh t} \cosh t = \coth t$

39. $H(t) = \tanh(e^t) \Rightarrow H'(t) = \operatorname{sech}^2(e^t) \cdot e^t = e^t \operatorname{sech}^2(e^t)$

40. $y = \sinh(\cosh x) \Rightarrow y' = \cosh(\cosh x) \cdot \sinh x$

41. $y = e^{\cosh 3x} \Rightarrow y' = e^{\cosh 3x} \cdot \sinh 3x \cdot 3 = 3e^{\cosh 3x} \sinh 3x$

$$42. y = x^2 \sinh^{-1}(2x) \Rightarrow y' = x^2 \cdot \frac{1}{\sqrt{1+(2x)^2}} \cdot 2 + \sinh^{-1}(2x) \cdot 2x = 2x \left[\frac{x}{\sqrt{1+4x^2}} + \sinh^{-1}(2x) \right]$$

$$43. y = \tanh^{-1} \sqrt{x} \Rightarrow y' = \frac{1}{1-(\sqrt{x})^2} \cdot \frac{1}{2} x^{-1/2} = \frac{1}{2\sqrt{x}(1-x)}$$

$$44. y = x \tanh^{-1} x + \ln \sqrt{1-x^2} = x \tanh^{-1} x + \frac{1}{2} \ln(1-x^2) \Rightarrow$$

$$y' = \tanh^{-1} x + \frac{x}{1-x^2} + \frac{1}{2} \left(\frac{1}{1-x^2} \right) (-2x) = \tanh^{-1} x$$

$$45. y = x \sinh^{-1}(x/3) - \sqrt{9+x^2} \Rightarrow$$

$$y' = \sinh^{-1}\left(\frac{x}{3}\right) + x \frac{1/3}{\sqrt{1+(x/3)^2}} - \frac{2x}{2\sqrt{9+x^2}} = \sinh^{-1}\left(\frac{x}{3}\right) + \frac{x}{\sqrt{9+x^2}} - \frac{x}{\sqrt{9+x^2}} = \sinh^{-1}\left(\frac{x}{3}\right)$$

$$46. y = \operatorname{sech}^{-1} \sqrt{1-x^2} \Rightarrow y' = -\frac{1}{\sqrt{1-x^2} \sqrt{1-(1-x^2)}} \cdot \frac{-2x}{2\sqrt{1-x^2}} = \frac{x}{(1-x^2)|x|}$$

$$47. y = \coth^{-1} \sqrt{x^2+1} \Rightarrow y' = \frac{1}{1-(x^2+1)} \cdot \frac{2x}{2\sqrt{x^2+1}} = -\frac{1}{x\sqrt{x^2+1}}$$

48.  For $y = a \cosh(x/a)$ with $a > 0$, we have the y -intercept equal to a . As a increases, the graph flattens.

49. (a) $y = 20 \cosh(x/20) - 15 \Rightarrow y' = 20 \sinh(x/20) \cdot \frac{1}{20} = \sinh(x/20)$. Since the right pole is positioned at $x = 7$, we have $y'(7) = \sinh \frac{7}{20} \approx 0.3572$.

- (b) If α is the angle between the tangent line and the x -axis, then $\tan \alpha = \text{slope of the line} = \sinh \frac{7}{20}$, so $\alpha = \tan^{-1}(\sinh \frac{7}{20}) \approx 0.343 \text{ rad} \approx 19.66^\circ$. Thus, the angle between the line and the pole is $\theta = 90^\circ - \alpha \approx 70.34^\circ$.

50. We differentiate the function twice, then substitute into the differential equation: $y = \frac{T}{\rho g} \cosh \frac{\rho g x}{T} \Rightarrow$

$$\frac{dy}{dx} = \frac{T}{\rho g} \sinh\left(\frac{\rho g x}{T}\right) \frac{\rho g}{T} = \sinh \frac{\rho g x}{T} \Rightarrow \frac{d^2 y}{dx^2} = \cosh\left(\frac{\rho g x}{T}\right) \frac{\rho g}{T} = \frac{\rho g}{T} \cosh \frac{\rho g x}{T}.$$

We evaluate the two sides separately: $\text{LHS} = \frac{d^2 y}{dx^2} = \frac{\rho g}{T} \cosh \frac{\rho g x}{T},$

$$\text{RHS} = \frac{\rho g}{T} \sqrt{1 + \left(\frac{dy}{dx}\right)^2} = \frac{\rho g}{T} \sqrt{1 + \sinh^2 \frac{\rho g x}{T}} = \frac{\rho g}{T} \cosh \frac{\rho g x}{T}, \text{ by the identity proved in Example 1(a).}$$

51. (a) $y = A \sinh mx + B \cosh mx \Rightarrow y' = mA \cosh mx + mB \sinh mx \Rightarrow$
 $y'' = m^2 A \sinh mx + m^2 B \cosh mx = m^2 (A \sinh mx + B \cosh mx) = m^2 y$

- (b) From part (a), a solution of $y'' = 9y$ is $y(x) = A \sinh 3x + B \cosh 3x$. So
 $-4 = y(0) = A \sinh 0 + B \cosh 0 = B$, so $B = -4$. Now $y'(x) = 3A \cosh 3x - 12 \sinh 3x \Rightarrow$
 $6 = y'(0) = 3A \Rightarrow A = 2$, so $y = 2 \sinh 3x - 4 \cosh 3x$.

$$52. \lim_{x \rightarrow \infty} \frac{\sinh x}{e^x} = \lim_{x \rightarrow \infty} \frac{e^x - e^{-x}}{2e^x} = \lim_{x \rightarrow \infty} \frac{1 - e^{-2x}}{2} = \frac{1 - 0}{2} = \frac{1}{2}$$

53. The tangent to $y = \cosh x$ has slope 1 when $y' = \sinh x = 1 \Rightarrow x = \sinh^{-1} 1 = \ln(1 + \sqrt{2})$, by Equation 3.

Since $\sinh x = 1$ and $y = \cosh x = \sqrt{1 + \sinh^2 x}$, we have $\cosh x = \sqrt{2}$. The point is $(\ln(1 + \sqrt{2}), \sqrt{2})$.

$$\begin{aligned} 54. \cosh x &= \cosh[\ln(\sec \theta + \tan \theta)] = \frac{1}{2} \left[e^{\ln(\sec \theta + \tan \theta)} + e^{-\ln(\sec \theta + \tan \theta)} \right] \\ &= \frac{1}{2} \left[\sec \theta + \tan \theta + \frac{1}{\sec \theta + \tan \theta} \right] = \frac{1}{2} \left[\sec \theta + \tan \theta + \frac{\sec \theta - \tan \theta}{(\sec \theta + \tan \theta)(\sec \theta - \tan \theta)} \right] \\ &= \frac{1}{2} \left[\sec \theta + \tan \theta + \frac{\sec \theta - \tan \theta}{\sec^2 \theta - \tan^2 \theta} \right] = \frac{1}{2} (\sec \theta + \tan \theta + \sec \theta - \tan \theta) = \sec \theta \end{aligned}$$

55. Let $u = \cosh x$. Then $du = \sinh x \, dx$, so $\int \sinh x \cosh^2 x \, dx = \int u^2 \, du = \frac{1}{3} u^3 + C = \frac{1}{3} \cosh^3 x + C$.

56. Let $u = 1 + 4x$. Then $du = 4 \, dx$, so $\int \sinh(1 + 4x) \, dx = \frac{1}{4} \int \sinh u \, du = \frac{1}{4} \cosh u + C = \frac{1}{4} \cosh(1 + 4x) + C$.

57. Let $u = \sqrt{x}$. Then $du = \frac{dx}{2\sqrt{x}}$ and $\int \frac{\sinh \sqrt{x}}{\sqrt{x}} \, dx = \int \sinh u \cdot 2 \, du = 2 \cosh u + C = 2 \cosh \sqrt{x} + C$.

58. Let $u = \cosh x$. Then $du = \sinh x \, dx$, and

$$\int \tanh x \, dx = \int \frac{\sinh x}{\cosh x} \, dx = \int \frac{du}{u} = \ln |u| + C = \ln(\cosh x) + C.$$

$$59. \int \frac{\cosh x}{\cosh^2 x - 1} \, dx = \int \frac{\cosh x}{\sinh^2 x} \, dx = \int \frac{\cosh x}{\sinh x} \cdot \frac{1}{\sinh x} \, dx = \int \coth x \operatorname{csch} x \, dx = -\operatorname{csch} x + C$$

60. Let $u = 2 + \tanh x$. Then $du = \operatorname{sech}^2 x \, dx$, so

$$\int \frac{\operatorname{sech}^2 x}{2 + \tanh x} \, dx = \int \frac{1}{u} \, du = \ln |u| + C = \ln |2 + \tanh x| + C = \ln(2 + \tanh x) + C$$

(since $2 + \tanh x > 1$).

61. Let $t = 3u$. Then $dt = 3 \, du$ and

$$\begin{aligned} \int_4^6 \frac{1}{\sqrt{t^2 - 9}} \, dt &= \int_{4/3}^2 \frac{1}{\sqrt{9u^2 - 9}} 3 \, du = \int_{4/3}^2 \frac{du}{\sqrt{u^2 - 1}} = \left[\cosh^{-1} u \right]_{4/3}^2 = \cosh^{-1} 2 - \cosh^{-1} \left(\frac{4}{3} \right) \quad \text{or} \\ &= \left[\cosh^{-1} u \right]_{4/3}^2 = \left[\ln(u + \sqrt{u^2 - 1}) \right]_{4/3}^2 \\ &= \ln(2 + \sqrt{3}) - \ln\left(\frac{4 + \sqrt{7}}{3}\right) = \ln\left(\frac{6 + 3\sqrt{3}}{4 + \sqrt{7}}\right) \end{aligned}$$

62. Let $u = 4t$. Then $du = 4 \, dt$ and

$$\begin{aligned} \int_0^1 \frac{dt}{\sqrt{16t^2 + 1}} &= \int_0^4 \frac{\frac{1}{4} du}{\sqrt{u^2 + 1}} = \frac{1}{4} \left[\sinh^{-1} u \right]_0^4 = \frac{1}{4} \left[\ln(u + \sqrt{u^2 + 1}) \right]_0^4 \\ &= \frac{1}{4} [\ln(4 + \sqrt{17}) - \ln 1] = \frac{1}{4} \ln(4 + \sqrt{17}) \end{aligned}$$

63. Let $u = e^x$. Then $du = e^x \, dx$ and $\int \frac{e^x}{1 - e^{2x}} \, dx = \int \frac{du}{1 - u^2} = \tanh^{-1} u + C = \tanh^{-1}(e^x) + C$

$$\left[\text{or } \frac{1}{2} \ln \left(\frac{1 + e^x}{1 - e^x} \right) + C \right].$$

64. We want $\int_0^1 \sinh cx \, dx = 1$. To calculate the integral, we put $u = cx$, so $du = c \, dx$, the upper limit becomes c , and the equation becomes

$$\frac{1}{c} \int_0^c \sinh u \, du = 1 \Leftrightarrow \frac{1}{c} [\cosh c - 1] = 1 \Leftrightarrow \cosh c - 1 = c.$$

We plot the function $f(c) = \cosh c - c - 1$, and see that its positive root lies at approximately $c = 1.62$. So the equation $\int_0^1 \sinh cx \, dx = 1$ holds for $c \approx 1.62$.

65. (a) From the graphs, we estimate

that the two curves $y = \cosh 2x$ and $y = 1 + \sinh x$ intersect at $x = 0$ and at $x = a \approx 0.481$.

- (b) We have found the two roots of the equation $\cosh 2x = 1 + \sinh x$ to be $x = 0$ and $x = a \approx 0.481$. Note from the first graph that $1 + \sinh x > \cosh 2x$ on the interval $(0, a)$, so the area between the two curves is

$$\begin{aligned} A &= \int_0^a (1 + \sinh x - \cosh 2x) \, dx = \left[x + \cosh x - \frac{1}{2} \sinh 2x \right]_0^a \\ &= [a + \cosh a - \frac{1}{2} \sinh 2a] - [0 + \cosh 0 - \frac{1}{2} \sinh 0] \approx 0.0402 \end{aligned}$$

66. The area of the triangle with vertices O , P , and $(\cosh t, 0)$ is $\frac{1}{2} \sinh t \cosh t$, and the area under the curve $x^2 - y^2 = 1$, from $x = 1$ to $x = \cosh t$, is $\int_1^{\cosh t} \sqrt{x^2 - 1} \, dx$. Therefore, the area of the shaded region is $A(t) = \frac{1}{2} \sinh t \cosh t - \int_1^{\cosh t} \sqrt{x^2 - 1} \, dx$. So, by FTC1,

$$\begin{aligned} A'(t) &= \frac{1}{2} (\cosh^2 t + \sinh^2 t) - \sqrt{\cosh^2 t - 1} \sinh t = \frac{1}{2} (\cosh^2 t + \sinh^2 t) - \sqrt{\sinh^2 t} \sinh t \\ &= \frac{1}{2} (\cosh^2 t + \sinh^2 t) - \sinh^2 t = \frac{1}{2} (\cosh^2 t - \sinh^2 t) = \frac{1}{2} (1) = \frac{1}{2} \end{aligned}$$

Thus $A(t) = \frac{1}{2}t + C$, since $A'(t) = \frac{1}{2}$. To calculate C , we let $t = 0$. Thus,

$$A(0) = \frac{1}{2} \sinh 0 \cosh 0 - \int_1^{\cosh 0} \sqrt{x^2 - 1} \, dx = \frac{1}{2} (0) + C \Rightarrow C = 0. \text{ Thus } A(t) = \frac{1}{2}t.$$

67. If $ae^x + be^{-x} = \alpha \cosh(x + \beta)$ [or $\alpha \sinh(x + \beta)$], then

$ae^x + be^{-x} = \frac{\alpha}{2} (e^{x+\beta} \pm e^{-x-\beta}) = \frac{\alpha}{2} (e^x e^\beta \pm e^{-x} e^{-\beta}) = (\frac{\alpha}{2} e^\beta) e^x \pm (\frac{\alpha}{2} e^{-\beta}) e^{-x}$. Comparing coefficients of e^x and e^{-x} , we have $a = \frac{\alpha}{2} e^\beta$ (1) and $b = \pm \frac{\alpha}{2} e^{-\beta}$ (2). We need to find α and β . Dividing equation (1) by equation (2) gives us $\frac{a}{b} = \pm e^{2\beta} \Rightarrow (*) \quad 2\beta = \ln(\pm \frac{a}{b}) \Rightarrow \beta = \frac{1}{2} \ln(\pm \frac{a}{b})$. Solving equations (1) and (2) for e^β gives us $e^\beta = \frac{2a}{\alpha}$ and $e^\beta = \pm \frac{\alpha}{2b}$, so $\frac{2a}{\alpha} = \pm \frac{\alpha}{2b} \Rightarrow \alpha^2 = \pm 4ab \Rightarrow \alpha = 2\sqrt{\pm ab}$.

(*) If $\frac{a}{b} > 0$, we use the $+$ sign and obtain a cosh function, whereas if $\frac{a}{b} < 0$, we use the $-$ sign and obtain a sinh function.

In summary, if a and b have the same sign, we have $ae^x + be^{-x} = 2\sqrt{ab} \cosh(x + \frac{1}{2} \ln \frac{a}{b})$, whereas, if a and b have the opposite sign, then $ae^x + be^{-x} = 2\sqrt{-ab} \sinh(x + \frac{1}{2} \ln(-\frac{a}{b}))$.

7.7 Indeterminate Forms and L'Hospital's Rule

The use of L'Hospital's Rule is indicated by an **H** above the equal sign: $\stackrel{\text{H}}{=}$.

1. (a) $\lim_{x \rightarrow a} \frac{f(x)}{g(x)}$ is an indeterminate form of type $\frac{0}{0}$.
 (b) $\lim_{x \rightarrow a} \frac{f(x)}{p(x)} = 0$ because the numerator approaches 0 while the denominator becomes large.
 (c) $\lim_{x \rightarrow a} \frac{h(x)}{p(x)} = 0$ because the numerator approaches a finite number while the denominator becomes large.
 (d) If $\lim_{x \rightarrow a} p(x) = \infty$ and $f(x) \rightarrow 0$ through positive values, then $\lim_{x \rightarrow a} \frac{p(x)}{f(x)} = \infty$. [For example, take $a = 0$, $p(x) = 1/x^2$, and $f(x) = x^2$.] If $f(x) \rightarrow 0$ through negative values, then $\lim_{x \rightarrow a} \frac{p(x)}{f(x)} = -\infty$. [For example, take $a = 0$, $p(x) = 1/x^2$, and $f(x) = -x^2$.] If $f(x) \rightarrow 0$ through both positive and negative values, then the limit might not exist. [For example, take $a = 0$, $p(x) = 1/x^2$, and $f(x) = x$.]
 (e) $\lim_{x \rightarrow a} \frac{p(x)}{q(x)}$ is an indeterminate form of type $\frac{\infty}{\infty}$.
 2. (a) $\lim_{x \rightarrow a} [f(x)p(x)]$ is an indeterminate form of type $0 \cdot \infty$.
 (b) When x is near a , $p(x)$ is large and $h(x)$ is near 1, so $h(x)p(x)$ is large. Thus, $\lim_{x \rightarrow a} [h(x)p(x)] = \infty$.
 (c) When x is near a , $p(x)$ and $q(x)$ are both large, so $p(x)q(x)$ is large. Thus, $\lim_{x \rightarrow a} [p(x)q(x)] = \infty$.
 3. (a) When x is near a , $f(x)$ is near 0 and $p(x)$ is large, so $f(x) - p(x)$ is large negative. Thus, $\lim_{x \rightarrow a} [f(x) - p(x)] = -\infty$.
 (b) $\lim_{x \rightarrow a} [p(x) - q(x)]$ is an indeterminate form of type $\infty - \infty$.
 (c) When x is near a , $p(x)$ and $q(x)$ are both large, so $p(x) + q(x)$ is large. Thus, $\lim_{x \rightarrow a} [p(x) + q(x)] = \infty$.
 4. (a) $\lim_{x \rightarrow a} [f(x)]^{q(x)}$ is an indeterminate form of type 0^0 .
 (b) If $y = [f(x)]^{p(x)}$, then $\ln y = p(x) \ln f(x)$. When x is near a , $p(x) \rightarrow \infty$ and $\ln f(x) \rightarrow -\infty$, so $\ln y \rightarrow -\infty$. Therefore, $\lim_{x \rightarrow a} [f(x)]^{p(x)} = \lim_{x \rightarrow a} y = \lim_{x \rightarrow a} e^{\ln y} = 0$, provided f^p is defined.
 (c) $\lim_{x \rightarrow a} [h(x)]^{p(x)}$ is an indeterminate form of type 1^∞ .
 (d) $\lim_{x \rightarrow a} [p(x)]^{f(x)}$ is an indeterminate form of type ∞^0 .
 (e) If $y = [p(x)]^{q(x)}$, then $\ln y = q(x) \ln p(x)$. When x is near a , $q(x) \rightarrow \infty$ and $\ln p(x) \rightarrow \infty$, so $\ln y \rightarrow \infty$. Therefore, $\lim_{x \rightarrow a} [p(x)]^{q(x)} = \lim_{x \rightarrow a} y = \lim_{x \rightarrow a} e^{\ln y} = \infty$.
 (f) $\lim_{x \rightarrow a} \sqrt[q(x)]{p(x)} = \lim_{x \rightarrow a} [p(x)]^{1/q(x)}$ is an indeterminate form of type ∞^0 .
 5. This limit has the form $\frac{0}{0}$. We can simply factor the numerator to evaluate this limit.

$$\lim_{x \rightarrow -1} \frac{x^2 - 1}{x + 1} = \lim_{x \rightarrow -1} \frac{(x + 1)(x - 1)}{x + 1} = \lim_{x \rightarrow -1} (x - 1) = -2$$

6. $\lim_{x \rightarrow -2} \frac{x+2}{x^2+3x+2} = \lim_{x \rightarrow -2} \frac{x+2}{(x+1)(x+2)} = \lim_{x \rightarrow -2} \frac{1}{x+1} = -1$
7. This limit has the form $\frac{0}{0}$. $\lim_{x \rightarrow 1} \frac{x^9-1}{x^5-1} \stackrel{H}{=} \lim_{x \rightarrow 1} \frac{9x^8}{5x^4} = \frac{9}{5} \lim_{x \rightarrow 1} x^4 = \frac{9}{5}(1) = \frac{9}{5}$
8. $\lim_{x \rightarrow 1} \frac{x^a-1}{x^b-1} \stackrel{H}{=} \lim_{x \rightarrow 1} \frac{ax^{a-1}}{bx^{b-1}} = \frac{a}{b}$
9. This limit has the form $\frac{0}{0}$. $\lim_{x \rightarrow (\pi/2)^+} \frac{\cos x}{1-\sin x} \stackrel{H}{=} \lim_{x \rightarrow (\pi/2)^+} \frac{-\sin x}{-\cos x} = \lim_{x \rightarrow (\pi/2)^+} \tan x = -\infty$.
10. $\lim_{x \rightarrow 0} \frac{x+\tan x}{\sin x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{1+\sec^2 x}{\cos x} = \frac{1+1^2}{1} = 2$
11. This limit has the form $\frac{0}{0}$. $\lim_{t \rightarrow 0} \frac{e^t-1}{t^3} \stackrel{H}{=} \lim_{t \rightarrow 0} \frac{e^t}{3t^2} = \infty$ since $e^t \rightarrow 1$ and $3t^2 \rightarrow 0^+$ as $t \rightarrow 0$.
12. $\lim_{t \rightarrow 0} \frac{e^{3t}-1}{t} \stackrel{H}{=} \lim_{t \rightarrow 0} \frac{3e^{3t}}{1} = 3$
13. This limit has the form $\frac{0}{0}$. $\lim_{x \rightarrow 0} \frac{\tan px}{\tan qx} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{p \sec^2 px}{q \sec^2 qx} = \frac{p(1)^2}{q(1)^2} = \frac{p}{q}$
14. $\lim_{\theta \rightarrow \pi/2} \frac{1-\sin \theta}{\csc \theta} = \frac{0}{1} = 0$. L'Hospital's Rule does not apply.
15. This limit has the form $\frac{\infty}{\infty}$. $\lim_{x \rightarrow \infty} \frac{\ln x}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{1/x}{1} = 0$
16. $\lim_{x \rightarrow \infty} \frac{e^x}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{1} = \lim_{x \rightarrow \infty} e^x = \infty$
17. $\lim_{x \rightarrow 0^+} [(\ln x)/x] = -\infty$ since $\ln x \rightarrow -\infty$ as $x \rightarrow 0^+$ and dividing by small values of x just increases the magnitude of the quotient $(\ln x)/x$. L'Hospital's Rule does not apply.
18. $\lim_{x \rightarrow \infty} \frac{\ln \ln x}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{\frac{1}{\ln x} \cdot \frac{1}{x}}{1} = \lim_{x \rightarrow \infty} \frac{1}{x \ln x} = 0$
19. This limit has the form $\frac{0}{0}$. $\lim_{t \rightarrow 0} \frac{5^t-3^t}{t} \stackrel{H}{=} \lim_{t \rightarrow 0} \frac{5^t \ln 5 - 3^t \ln 3}{1} = \ln 5 - \ln 3 = \ln \frac{5}{3}$
20. $\lim_{x \rightarrow 1} \frac{\ln x}{\sin \pi x} \stackrel{H}{=} \lim_{x \rightarrow 1} \frac{1/x}{\pi \cos \pi x} = \frac{1}{\pi(-1)} = -\frac{1}{\pi}$
21. This limit has the form $\frac{0}{0}$. $\lim_{x \rightarrow 0} \frac{e^x-1-x}{x^2} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{e^x-1}{2x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{e^x}{2} = \frac{1}{2}$
22. $\lim_{x \rightarrow 0} \frac{e^x-1-x-x^2/2}{x^3} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{e^x-1-x}{3x^2} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{e^x-1}{6x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{e^x}{6} = \frac{1}{6}$
23. This limit has the form $\frac{\infty}{\infty}$. $\lim_{x \rightarrow \infty} \frac{e^x}{x^3} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{3x^2} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{6x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{6} = \infty$
24. $\lim_{x \rightarrow 0} \frac{\sin x}{\sinh x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\cos x}{\cosh x} = \frac{1}{1} = 1$
25. This limit has the form $\frac{0}{0}$. $\lim_{x \rightarrow 0} \frac{\sin^{-1} x}{x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{1/\sqrt{1-x^2}}{1} = \lim_{x \rightarrow 0} \frac{1}{\sqrt{1-x^2}} = \frac{1}{1} = 1$
26. $\lim_{x \rightarrow 0} \frac{\sin x - x}{x^3} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\cos x - 1}{3x^2} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{-\sin x}{6x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{-\cos x}{6} = -\frac{1}{6}$
27. This limit has the form $\frac{0}{0}$. $\lim_{x \rightarrow 0} \frac{1-\cos x}{x^2} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\sin x}{2x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\cos x}{2} = \frac{1}{2}$

$$28. \lim_{x \rightarrow \infty} \frac{(\ln x)^2}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{2(\ln x)(1/x)}{1} = 2 \lim_{x \rightarrow \infty} \frac{\ln x}{x} \stackrel{H}{=} 2 \lim_{x \rightarrow \infty} \frac{1/x}{1} = 2(0) = 0$$

$$29. \lim_{x \rightarrow 0} \frac{x + \sin x}{x + \cos x} = \frac{0 + 0}{0 + 1} = \frac{0}{1} = 0. \text{ L'Hospital's Rule does not apply.}$$

$$30. \lim_{x \rightarrow 0} \frac{\cos mx - \cos nx}{x^2} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{-m \sin mx + n \sin nx}{2x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{-m^2 \cos mx + n^2 \cos nx}{2} = \frac{1}{2}(n^2 - m^2)$$

$$31. \text{ This limit has the form } \frac{\infty}{\infty}. \lim_{x \rightarrow \infty} \frac{x}{\ln(1 + 2e^x)} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{1}{\frac{1}{1 + 2e^x} \cdot 2e^x} = \lim_{x \rightarrow \infty} \frac{1 + 2e^x}{2e^x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{2e^x}{2e^x} = 1$$

$$32. \lim_{x \rightarrow 0} \frac{x}{\tan^{-1}(4x)} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{1}{\frac{1}{1 + (4x)^2} \cdot 4} = \lim_{x \rightarrow 0} \frac{1 + 16x^2}{4} = \frac{1}{4}$$

$$33. \text{ This limit has the form } \frac{0}{0}. \lim_{x \rightarrow 1} \frac{1 - x + \ln x}{1 + \cos \pi x} \stackrel{H}{=} \lim_{x \rightarrow 1} \frac{-1 + 1/x}{-\pi \sin \pi x} \stackrel{H}{=} \lim_{x \rightarrow 1} \frac{-1/x^2}{-\pi^2 \cos \pi x} = \frac{-1}{-\pi^2(-1)} = -\frac{1}{\pi^2}$$

$$34. \lim_{x \rightarrow \infty} \frac{\sqrt{x^2 + 2}}{\sqrt{2x^2 + 1}} = \lim_{x \rightarrow \infty} \sqrt{\frac{x^2 + 2}{2x^2 + 1}} = \sqrt{\lim_{x \rightarrow \infty} \frac{x^2 + 2}{2x^2 + 1}} = \sqrt{\lim_{x \rightarrow \infty} \frac{1 + 2/x^2}{2 + 1/x^2}} = \sqrt{\frac{1}{2}}$$

$$35. \text{ This limit has the form } \frac{0}{0}. \lim_{x \rightarrow 1} \frac{x^a - ax + a - 1}{(x - 1)^2} \stackrel{H}{=} \lim_{x \rightarrow 1} \frac{ax^{a-1} - a}{2(x - 1)} \stackrel{H}{=} \lim_{x \rightarrow 1} \frac{a(a - 1)x^{a-2}}{2} = \frac{a(a - 1)}{2}$$

$$36. \lim_{x \rightarrow 0} \frac{1 - e^{-2x}}{\sec x} = \frac{1 - 1}{1} = 0. \text{ L'Hospital's Rule does not apply.}$$

37. This limit has the form $0 \cdot (-\infty)$. We need to write this product as a quotient, but keep in mind that we will have to differentiate both the numerator and the denominator. If we differentiate $\frac{1}{\ln x}$, we get a complicated expression that results in a more difficult limit. Instead we write the quotient as $\frac{\ln x}{x^{-1/2}}$.

$$\lim_{x \rightarrow 0^+} \sqrt{x} \ln x = \lim_{x \rightarrow 0^+} \frac{\ln x}{x^{-1/2}} \stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{1/x}{-\frac{1}{2}x^{-3/2}} \cdot \frac{-2x^{3/2}}{-2x^{3/2}} = \lim_{x \rightarrow 0^+} (-2\sqrt{x}) = 0$$

$$38. \lim_{x \rightarrow -\infty} x^2 e^x = \lim_{x \rightarrow -\infty} \frac{x^2}{e^{-x}} \stackrel{H}{=} \lim_{x \rightarrow -\infty} \frac{2x}{-e^{-x}} \stackrel{H}{=} \lim_{x \rightarrow -\infty} \frac{2}{e^{-x}} = \lim_{x \rightarrow -\infty} 2e^x = 0$$

39. This limit has the form $\infty \cdot 0$. We'll change it to the form $\frac{0}{0}$.

$$\lim_{x \rightarrow 0} \cot 2x \sin 6x = \lim_{x \rightarrow 0} \frac{\sin 6x}{\tan 2x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{6 \cos 6x}{2 \sec^2 2x} = \frac{6(1)}{2(1)^2} = 3$$

$$40. \lim_{x \rightarrow 0^+} \sin x \ln x = \lim_{x \rightarrow 0^+} \frac{\ln x}{\csc x} \stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{1/x}{-\csc x \cot x} = - \lim_{x \rightarrow 0^+} \left(\frac{\sin x}{x} \cdot \tan x \right) \\ = - \left(\lim_{x \rightarrow 0^+} \frac{\sin x}{x} \right) \left(\lim_{x \rightarrow 0^+} \tan x \right) = -1 \cdot 0 = 0$$

$$41. \text{ This limit has the form } \infty \cdot 0. \lim_{x \rightarrow \infty} x^3 e^{-x^2} = \lim_{x \rightarrow \infty} \frac{x^3}{e^{x^2}} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{3x^2}{2xe^{x^2}} = \lim_{x \rightarrow \infty} \frac{3x}{2e^{x^2}} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{3}{4xe^{x^2}} = 0$$

$$42. \lim_{x \rightarrow \pi/4} (1 - \tan x) \sec x = (1 - 1)\sqrt{2} = 0. \text{ L'Hospital's Rule does not apply.}$$

43. This limit has the form $0 \cdot (-\infty)$.

$$\lim_{x \rightarrow 1^+} \ln x \tan(\pi x/2) = \lim_{x \rightarrow 1^+} \frac{\ln x}{\cot(\pi x/2)} \stackrel{H}{=} \lim_{x \rightarrow 1^+} \frac{1/x}{(-\pi/2) \csc^2(\pi x/2)} = \frac{1}{(-\pi/2)(1)^2} = -\frac{2}{\pi}$$

$$44. \lim_{x \rightarrow \infty} x \tan(1/x) = \lim_{x \rightarrow \infty} \frac{\tan(1/x)}{1/x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{\sec^2(1/x)(-1/x^2)}{-1/x^2} = \lim_{x \rightarrow \infty} \sec^2(1/x) = 1^2 = 1$$

$$45. \lim_{x \rightarrow 0} \left(\frac{1}{x} - \csc x \right) = \lim_{x \rightarrow 0} \left(\frac{1}{x} - \frac{1}{\sin x} \right) = \lim_{x \rightarrow 0} \frac{\sin x - x}{x \sin x}$$

$$\stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\cos x - 1}{x \cos x + \sin x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{-\sin x}{2 \cos x - x \sin x} = \frac{0}{2} = 0$$

$$46. \lim_{x \rightarrow 0} (\csc x - \cot x) = \lim_{x \rightarrow 0} \left(\frac{1}{\sin x} - \frac{\cos x}{\sin x} \right) = \lim_{x \rightarrow 0} \frac{1 - \cos x}{\sin x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\sin x}{\cos x} = 0$$

47. We will multiply and divide by the conjugate of the expression to change the form of the expression.

$$\lim_{x \rightarrow \infty} (\sqrt{x^2 + x} - x) = \lim_{x \rightarrow \infty} \left(\frac{\sqrt{x^2 + x} - x}{1} \cdot \frac{\sqrt{x^2 + x} + x}{\sqrt{x^2 + x} + x} \right) = \lim_{x \rightarrow \infty} \frac{(x^2 + x) - x^2}{\sqrt{x^2 + x} + x}$$

$$= \lim_{x \rightarrow \infty} \frac{x}{\sqrt{x^2 + x} + x} = \lim_{x \rightarrow \infty} \frac{1}{\sqrt{1 + 1/x} + 1} = \frac{1}{\sqrt{1 + 1} + 1} = \frac{1}{2}.$$

As an alternate solution, write $\sqrt{x^2 + x} - x$ as $\sqrt{x^2 + x} - \sqrt{x^2}$, factor out $\sqrt{x^2}$, rewrite as $(\sqrt{1 + 1/x} - 1)/(1/x)$, and apply l'Hospital's Rule.

$$48. \lim_{x \rightarrow 1} \left(\frac{1}{\ln x} - \frac{1}{x-1} \right) = \lim_{x \rightarrow 1} \frac{x-1 - \ln x}{(x-1) \ln x} \stackrel{H}{=} \lim_{x \rightarrow 1} \frac{1 - 1/x}{(x-1)(1/x) + \ln x} \cdot \frac{x}{x}$$

$$= \lim_{x \rightarrow 1} \frac{x-1}{x-1+x \ln x} \stackrel{H}{=} \lim_{x \rightarrow 1} \frac{1}{1+1+\ln x} = \frac{1}{2+0} = \frac{1}{2}$$

49. The limit has the form $\infty - \infty$ and we will change the form to a product by factoring out x .

$$\lim_{x \rightarrow \infty} (x - \ln x) = \lim_{x \rightarrow \infty} x \left(1 - \frac{\ln x}{x} \right) = \infty \text{ since } \lim_{x \rightarrow \infty} \frac{\ln x}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{1/x}{1} = 0.$$

50. As $x \rightarrow \infty$, $1/x \rightarrow 0$, and $e^{1/x} \rightarrow 1$. So the limit has the form $\infty - \infty$ and we will change the form to a product by factoring out x .

$$\lim_{x \rightarrow \infty} (xe^{1/x} - x) = \lim_{x \rightarrow \infty} x(e^{1/x} - 1) = \lim_{x \rightarrow \infty} \frac{e^{1/x} - 1}{1/x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^{1/x}(-1/x^2)}{-1/x^2} = \lim_{x \rightarrow \infty} e^{1/x} = e^0 = 1$$

51. $y = x^{x^2} \Rightarrow \ln y = x^2 \ln x$, so

$$\lim_{x \rightarrow 0^+} \ln y = \lim_{x \rightarrow 0^+} x^2 \ln x = \lim_{x \rightarrow 0^+} \frac{\ln x}{1/x^2} \stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{1/x}{-2/x^3} = \lim_{x \rightarrow 0^+} \left(-\frac{1}{2} x^2 \right) = 0 \Rightarrow$$

$$\lim_{x \rightarrow 0^+} x^{x^2} = \lim_{x \rightarrow 0^+} e^{\ln y} = e^0 = 1.$$

52. $y = (\tan 2x)^x \Rightarrow \ln y = x \cdot \ln \tan 2x$, so

$$\lim_{x \rightarrow 0^+} \ln y = \lim_{x \rightarrow 0^+} x \cdot \ln \tan 2x = \lim_{x \rightarrow 0^+} \frac{\ln \tan 2x}{1/x}$$

$$\stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{(1/\tan 2x)(2 \sec^2 2x)}{-1/x^2} = \lim_{x \rightarrow 0^+} \frac{-2x^2 \cos 2x}{\sin 2x \cos^2 2x} = \lim_{x \rightarrow 0^+} \frac{2x}{\sin 2x} \cdot \lim_{x \rightarrow 0^+} \frac{-x}{\cos 2x} = 1 \cdot 0 = 0 =$$

$$\lim_{x \rightarrow 0^+} (\tan 2x)^x = \lim_{x \rightarrow 0^+} e^{\ln y} = e^0 = 1.$$

53. $y = (1 - 2x)^{1/x} \Rightarrow \ln y = \frac{1}{x} \ln(1 - 2x)$, so $\lim_{x \rightarrow 0} \ln y = \lim_{x \rightarrow 0} \frac{\ln(1 - 2x)}{x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{-2/(1 - 2x)}{1} = -2 \Rightarrow$

$$\lim_{x \rightarrow 0} (1 - 2x)^{1/x} = \lim_{x \rightarrow 0} e^{\ln y} = e^{-2}.$$

$$54. y = \left(1 + \frac{a}{x}\right)^{bx} \Rightarrow \ln y = bx \ln\left(1 + \frac{a}{x}\right), \text{ so}$$

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{b \ln(1 + a/x)}{1/x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{b \left(\frac{1}{1 + a/x}\right) \left(-\frac{a}{x^2}\right)}{-1/x^2} = \lim_{x \rightarrow \infty} \frac{ab}{1 + a/x} = ab \Rightarrow$$

$$\lim_{x \rightarrow \infty} \left(1 + \frac{a}{x}\right)^{bx} = \lim_{x \rightarrow \infty} e^{\ln y} = e^{ab}.$$

$$55. y = \left(1 + \frac{3}{x} + \frac{5}{x^2}\right)^x \Rightarrow \ln y = x \ln\left(1 + \frac{3}{x} + \frac{5}{x^2}\right) \Rightarrow$$

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln\left(1 + \frac{3}{x} + \frac{5}{x^2}\right)}{1/x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{\left(-\frac{3}{x^2} - \frac{10}{x^3}\right) / \left(1 + \frac{3}{x} + \frac{5}{x^2}\right)}{-1/x^2} = \lim_{x \rightarrow \infty} \frac{3 + \frac{10}{x}}{1 + \frac{3}{x} + \frac{5}{x^2}} = 3,$$

$$\text{so } \lim_{x \rightarrow \infty} \left(1 + \frac{3}{x} + \frac{5}{x^2}\right)^x = \lim_{x \rightarrow \infty} e^{\ln y} = e^3.$$

$$56. y = x^{(\ln 2)/(1 + \ln x)} \Rightarrow \ln y = \frac{\ln 2}{1 + \ln x} \ln x \Rightarrow$$

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{(\ln 2)(\ln x)}{1 + \ln x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{(\ln 2)(1/x)}{1/x} = \lim_{x \rightarrow \infty} \ln 2 = \ln 2,$$

$$\text{so } \lim_{x \rightarrow \infty} x^{(\ln 2)/(1 + \ln x)} = \lim_{x \rightarrow \infty} e^{\ln y} = e^{\ln 2} = 2.$$

$$57. y = x^{1/x} \Rightarrow \ln y = (1/x) \ln x \Rightarrow \lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln x}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{1/x}{1} = 0 \Rightarrow$$

$$\lim_{x \rightarrow \infty} x^{1/x} = \lim_{x \rightarrow \infty} e^{\ln y} = e^0 = 1$$

$$58. y = (e^x + x)^{1/x} \Rightarrow \ln y = \frac{1}{x} \ln(e^x + x), \text{ so}$$

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln(e^x + x)}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x + 1}{e^x + x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{e^x + 1} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{e^x} = 1 \Rightarrow$$

$$\lim_{x \rightarrow \infty} (e^x + x)^{1/x} = \lim_{x \rightarrow \infty} e^{\ln y} = e^1 = e.$$

$$59. y = \left(\frac{x}{x+1}\right)^x \Rightarrow \ln y = x \ln\left(\frac{x}{x+1}\right) \Rightarrow$$

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} x \ln\left(\frac{x}{x+1}\right) = \lim_{x \rightarrow \infty} \frac{\ln x - \ln(x+1)}{1/x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{1/x - 1/(x+1)}{-1/x^2}$$

$$= \lim_{x \rightarrow \infty} \left(-x + \frac{x^2}{x+1}\right) = \lim_{x \rightarrow \infty} \frac{-x}{x+1} = -1$$

$$\text{so } \lim_{x \rightarrow \infty} \left(\frac{x}{x+1}\right)^x = \lim_{x \rightarrow \infty} e^{\ln y} = e^{-1}$$

$$\text{Or: } \lim_{x \rightarrow \infty} \left(\frac{x}{x+1}\right)^x = \lim_{x \rightarrow \infty} \left[\left(\frac{x+1}{x}\right)^{-1}\right]^x = \left[\lim_{x \rightarrow \infty} \left(1 + \frac{1}{x}\right)^x\right]^{-1} = e^{-1}$$

$$60. y = (\cos 3x)^{5/x} \Rightarrow \ln y = \frac{5}{x} \ln(\cos 3x) \Rightarrow \lim_{x \rightarrow 0} \ln y = 5 \lim_{x \rightarrow 0} \frac{\ln(\cos 3x)}{x} \stackrel{H}{=} 5 \lim_{x \rightarrow 0} \frac{-3 \tan 3x}{1} = 0,$$

$$\text{so } \lim_{x \rightarrow 0} (\cos 3x)^{5/x} = e^0 = 1.$$

$$61. y = (\cos x)^{1/x^2} \Rightarrow \ln y = \frac{1}{x^2} \ln \cos x \Rightarrow$$

$$\lim_{x \rightarrow 0^+} \ln y = \lim_{x \rightarrow 0^+} \frac{\ln \cos x}{x^2} \stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{-\tan x}{2x} \stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{-\sec^2 x}{2} = -\frac{1}{2} \Rightarrow$$

$$\lim_{x \rightarrow 0^+} (\cos x)^{1/x^2} = \lim_{x \rightarrow 0^+} e^{\ln y} = e^{-1/2} = 1/\sqrt{e}$$

$$62. y = \left(\frac{2x-3}{2x+5} \right)^{2x+1} \Rightarrow \ln y = (2x+1) \ln \left(\frac{2x-3}{2x+5} \right) \Rightarrow$$

$$\lim_{x \rightarrow \infty} \ln y = \lim_{x \rightarrow \infty} \frac{\ln(2x-3) - \ln(2x+5)}{1/(2x+1)} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{2/(2x-3) - 2/(2x+5)}{-2/(2x+1)^2} = \lim_{x \rightarrow \infty} \frac{-8(2x+1)^2}{(2x-3)(2x+5)}$$

$$= \lim_{x \rightarrow \infty} \frac{-8(2+1/x)^2}{(2-3/x)(2+5/x)} = -8 \Rightarrow \lim_{x \rightarrow \infty} \left(\frac{2x-3}{2x+5} \right)^{2x+1} = e^{-8}$$

63.

From the graph, it appears that $\lim_{x \rightarrow \infty} x [\ln(x+5) - \ln x] = 5$.

To prove this, we first note that

$$\ln(x+5) - \ln x = \ln \frac{x+5}{x} = \ln \left(1 + \frac{5}{x} \right) \rightarrow \ln 1 = 0 \text{ as } x \rightarrow \infty. \text{ Thus,}$$

$$\begin{aligned} \lim_{x \rightarrow \infty} x [\ln(x+5) - \ln x] &= \lim_{x \rightarrow \infty} \frac{\ln(x+5) - \ln x}{1/x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{\frac{1}{x+5} - \frac{1}{x}}{-1/x^2} \\ &= \lim_{x \rightarrow \infty} \left[\frac{x - (x+5)}{x(x+5)} \cdot \frac{-x^2}{1} \right] = \lim_{x \rightarrow \infty} \frac{5x^2}{x^2 + 5x} = 5 \end{aligned}$$

64.

From the graph, it appears that $\lim_{x \rightarrow \pi/4} (\tan x)^{\tan 2x} \approx 0.368$.

The limit has the form 1^∞ . Now $y = (\tan x)^{\tan 2x} \Rightarrow$

$\ln y = \tan 2x \ln(\tan x)$, so

$$\lim_{x \rightarrow \pi/4} \ln y = \lim_{x \rightarrow \pi/4} \frac{\ln(\tan x)}{\cot 2x} \stackrel{H}{=} \lim_{x \rightarrow \pi/4} \frac{\sec^2 x / \tan x}{-2 \csc^2 2x} = \frac{2/1}{-2(1)} = -1$$

$$\Rightarrow \lim_{x \rightarrow \pi/4} (\tan x)^{\tan 2x} = \lim_{x \rightarrow \pi/4} e^{\ln y} = e^{-1} = 1/e \approx 0.3679.$$

65.

From the graph, it appears that

$$\lim_{x \rightarrow 0} \frac{f(x)}{g(x)} = \lim_{x \rightarrow 0} \frac{f'(x)}{g'(x)} = 0.25. \text{ We calculate}$$

$$\lim_{x \rightarrow 0} \frac{f(x)}{g(x)} = \lim_{x \rightarrow 0} \frac{e^x - 1}{x^3 + 4x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{e^x}{3x^2 + 4} = \frac{1}{4}.$$

66.

From the graph, it appears that $\lim_{x \rightarrow 0} \frac{f(x)}{g(x)} = \lim_{x \rightarrow 0} \frac{f'(x)}{g'(x)} = 4$.

We calculate

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{f(x)}{g(x)} &= \lim_{x \rightarrow 0} \frac{2x \sin x}{\sec x - 1} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{2(x \cos x + \sin x)}{\sec x \tan x} \\ &\stackrel{H}{=} \lim_{x \rightarrow 0} \frac{2(-x \sin x + \cos x + \cos x)}{\sec x(\sec^2 x) + \tan x(\sec x \tan x)} = \frac{4}{1} = 4 \end{aligned}$$

- 67.
- $y = f(x) = xe^{-x}$
- A.
- $D = \mathbb{R}$
- B. Intercepts are 0 C. No symmetry

$$\text{D. } \lim_{x \rightarrow \infty} xe^{-x} = \lim_{x \rightarrow \infty} \frac{x}{e^x} \stackrel{\text{H}}{=} \lim_{x \rightarrow \infty} \frac{1}{e^x} = 0, \text{ so } y = 0 \text{ is a HA.}$$

$$\lim_{x \rightarrow -\infty} xe^{-x} = -\infty \quad \text{E. } f'(x) = e^{-x} - xe^{-x} = e^{-x}(1-x) > 0 \Leftrightarrow$$

$x < 1$, so f is increasing on $(-\infty, 1)$ and decreasing on $(1, \infty)$.

F. Absolute and local maximum value $f(1) = 1/e$.

G. $f''(x) = e^{-x}(x-2) > 0 \Leftrightarrow x > 2$, so f is CU on $(2, \infty)$ and CD on $(-\infty, 2)$. IP at $(2, 2/e^2)$

- 68.
- $y = f(x) = x(\ln x)^2$
- A.
- $D = (0, \infty)$
- B.
- x
- intercept = 1, no
- y
- intercept C. No symmetry

$$\text{D. } \lim_{x \rightarrow \infty} x(\ln x)^2 = \infty, \lim_{x \rightarrow 0^+} x(\ln x)^2 = \lim_{x \rightarrow 0^+} \frac{(\ln x)^2}{1/x} \stackrel{\text{H}}{=} \lim_{x \rightarrow 0^+} \frac{2(\ln x)(1/x)}{-1/x^2} = \lim_{x \rightarrow 0^+} \frac{2 \ln x}{-1/x} \stackrel{\text{H}}{=}$$

$$\lim_{x \rightarrow 0^+} \frac{2/x}{1/x^2} = \lim_{x \rightarrow 0^+} 2x = 0, \text{ no asymptote} \quad \text{E. } f'(x) = (\ln x)^2 + 2 \ln x = (\ln x)(\ln x + 2) = 0 \text{ when } \ln x = 0$$

$\Leftrightarrow x = 1$ and when $\ln x = -2 \Leftrightarrow x = e^{-2}$. $f'(x) > 0$ when $0 < x < e^{-2}$ and when $x > 1$, so

f is increasing on $(0, e^{-2})$ and $(1, \infty)$ and decreasing on $(e^{-2}, 1)$.

F. Local maximum value $f(e^{-2}) = 4e^{-2}$,

local minimum value $f(1) = 0$

$$\text{G. } f''(x) = 2(\ln x)(1/x) + 2/x = (2/x)(\ln x + 1) = 0$$

when $\ln x = -1 \Leftrightarrow x = e^{-1}$. $f''(x) > 0 \Leftrightarrow$

$x > 1/e$, so f is CU on $(1/e, \infty)$, CD on $(0, 1/e)$.

IP at $(1/e, 1/e)$

- 69.
- $y = f(x) = xe^{-x^2}$
- A.
- $D = \mathbb{R}$
- B. Intercepts are 0 C.
- $f(-x) = -f(x)$
- , so the curve is symmetric

about the origin. D. $\lim_{x \rightarrow \pm\infty} xe^{-x^2} = \lim_{x \rightarrow \pm\infty} \frac{x}{e^{x^2}} \stackrel{\text{H}}{=} \lim_{x \rightarrow \pm\infty} \frac{1}{2xe^{x^2}} = 0$, so $y = 0$ is a HA.

E. $f'(x) = e^{-x^2} - 2x^2e^{-x^2} = e^{-x^2}(1 - 2x^2) > 0 \Leftrightarrow x^2 < \frac{1}{2} \Leftrightarrow |x| < \frac{1}{\sqrt{2}}$, so f is increasing on

$(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}})$ and decreasing on $(-\infty, -\frac{1}{\sqrt{2}})$ and $(\frac{1}{\sqrt{2}}, \infty)$. F. Local maximum value $f(\frac{1}{\sqrt{2}}) = 1/\sqrt{2}e$, local

minimum value $f(-\frac{1}{\sqrt{2}}) = -1/\sqrt{2}e$ G. $f''(x) = -2xe^{-x^2}(1 - 2x^2) - 4xe^{-x^2} = 2xe^{-x^2}(2x^2 - 3) > 0$

$\Leftrightarrow x > \sqrt{\frac{3}{2}}$ or $-\sqrt{\frac{3}{2}} < x < 0$, so f is CU on $(\sqrt{\frac{3}{2}}, \infty)$

and $(-\sqrt{\frac{3}{2}}, 0)$ and CD on $(-\infty, -\sqrt{\frac{3}{2}})$ and $(0, \sqrt{\frac{3}{2}})$.

IP are $(0, 0)$ and $(\pm\sqrt{\frac{3}{2}}, \pm\sqrt{\frac{3}{2}}e^{-3/2})$.

70. $y = f(x) = e^x/x$ A. $D = \{x \mid x \neq 0\}$ B. No intercept C. No symmetry D. $\lim_{x \rightarrow \infty} \frac{e^x}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{1} = \infty$,

$$\lim_{x \rightarrow -\infty} \frac{e^x}{x} = 0, \text{ so } y = 0 \text{ is a HA. } \lim_{x \rightarrow 0^+} \frac{e^x}{x} = \infty, \lim_{x \rightarrow 0^-} \frac{e^x}{x} = -\infty, \text{ so } x = 0 \text{ is a VA.}$$

E. $f'(x) = \frac{xe^x - e^x}{x^2} > 0 \Leftrightarrow (x-1)e^x > 0 \Leftrightarrow x > 1$,

so f is increasing on $(1, \infty)$, and decreasing on $(-\infty, 0)$ and $(0, 1)$.

F. $f(1) = e$ is a local minimum value.

G. $f''(x) = \frac{x^2(xe^x) - 2x(xe^x - e^x)}{x^4} = \frac{e^x(x^2 - 2x + 2)}{x^3} > 0$

$\Leftrightarrow x > 0$ since $x^2 - 2x + 2 > 0$ for all x . So f is CU on $(0, \infty)$ and CD

on $(-\infty, 0)$. No IP

71. $y = f(x) = x - \ln(1+x)$ A. $D = \{x \mid x > -1\} = (-1, \infty)$ B. Intercepts are 0 C. No symmetry

D. $\lim_{x \rightarrow -1^+} [x - \ln(1+x)] = \infty$, so $x = -1$ is a VA. $\lim_{x \rightarrow \infty} [x - \ln(1+x)] = \lim_{x \rightarrow \infty} x \left[1 - \frac{\ln(1+x)}{x} \right] = \infty$,

since $\lim_{x \rightarrow \infty} \frac{\ln(1+x)}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{1/(1+x)}{1} = 0$.

E. $f'(x) = 1 - \frac{1}{1+x} = \frac{x}{1+x} > 0 \Leftrightarrow x > 0$ since $x+1 > 0$.

So f is increasing on $(0, \infty)$ and decreasing on $(-1, 0)$.

F. $f(0) = 0$ is an absolute minimum.

G. $f''(x) = 1/(1+x)^2 > 0$, so f is CU on $(-1, \infty)$.

72. $y = f(x) = e^x - 3e^{-x} - 4x$ A. $D = \mathbb{R}$ B. y -intercept = -2; x -intercept ≈ 2.22 C. No symmetry

D. $\lim_{x \rightarrow \infty} (e^x - 3e^{-x} - 4x) = \lim_{x \rightarrow \infty} x \left(\frac{e^x}{x} - 3\frac{e^{-x}}{x} - 4 \right) = \infty$, since $\lim_{x \rightarrow \infty} \frac{e^x}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{1} = \infty$.

Similarly, $\lim_{x \rightarrow -\infty} (e^x - 3e^{-x} - 4x) = -\infty$. No HA; no VA

E. $f'(x) = e^x + 3e^{-x} - 4 = e^{-x}(e^{2x} - 4e^x + 3) = e^{-x}(e^x - 3)(e^x - 1) > 0 \Leftrightarrow e^x > 3 \text{ or } e^x < 1 \Leftrightarrow$

$x > \ln 3 \text{ or } x < 0$. So f is increasing on $(-\infty, 0)$ and $(\ln 3, \infty)$ and

decreasing on $(0, \ln 3)$. F. Local maximum value $f(0) = -2$,

local minimum value $f(\ln 3) = 2 - 4 \ln 3$

G. $f''(x) = e^x - 3e^{-x} = e^{-x}(e^{2x} - 3) > 0 \Leftrightarrow e^{2x} > 3 \Leftrightarrow$

$x > \frac{1}{2} \ln 3$, so f is CU on $(\frac{1}{2} \ln 3, \infty)$ and CD on $(-\infty, \frac{1}{2} \ln 3)$.

IP at $(\frac{1}{2} \ln 3, -2 \ln 3)$.

(b) $y = f(x) = x^{-x}$. We note that

$$\ln f(x) = \ln x^{-x} = -x \ln x = -\frac{\ln x}{1/x}, \text{ so}$$

$$\lim_{x \rightarrow 0^+} \ln f(x) \stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{-1/x}{-x^{-2}} = \lim_{x \rightarrow 0^+} x = 0. \text{ Thus}$$

$$\lim_{x \rightarrow 0^+} f(x) = \lim_{x \rightarrow 0^+} e^{\ln f(x)} = e^0 = 1.$$

(c) From the graph, it appears that there is a local and absolute maximum of about

$$f(0.37) \approx 1.44. \text{ To find the exact value, we differentiate: } f(x) = x^{-x} = e^{-x \ln x} \Rightarrow$$

$$f'(x) = e^{-x \ln x} \left[-x \left(\frac{1}{x} \right) + \ln x (-1) \right] = -x^{-x} (1 + \ln x). \text{ This is 0 only when } 1 + \ln x = 0 \Leftrightarrow$$

$x = e^{-1}$. Also $f'(x)$ changes from positive to negative at e^{-1} . So the maximum value is

$$f(1/e) = (1/e)^{-1/e} = e^{1/e}.$$

(d) We differentiate again to get

$$\begin{aligned} f''(x) &= -x^{-x}(1/x) + (1 + \ln x)^2(x^{-x}) \\ &= x^{-x} [(1 + \ln x)^2 - 1/x] \end{aligned}$$

From the graph of $f''(x)$, it seems that $f''(x)$ changes from negative to positive at $x = 1$, so we estimate that f has an IP at $x = 1$.

74. (a) $f(x) = (\sin x)^{\sin x}$ is continuous where $\sin x > 0$, that is,

on intervals of the form $(2n\pi, (2n+1)\pi)$, so we have

graphed f on $(0, \pi)$.

(b) $y = (\sin x)^{\sin x} \Rightarrow \ln y = \sin x \ln \sin x$, so

$$\lim_{x \rightarrow 0^+} \ln y = \lim_{x \rightarrow 0^+} \sin x \ln \sin x = \lim_{x \rightarrow 0^+} \frac{\ln \sin x}{\csc x} \stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{\cot x}{-\csc x \cot x} = \lim_{x \rightarrow 0^+} (-\sin x) = 0$$

$$\Rightarrow \lim_{x \rightarrow 0^+} y = e^0 = 1.$$

(c) It appears that we have a local maximum at $(1.57, 1)$ and local minima at $(0.38, 0.69)$ and

$$(2.76, 0.69). \quad y = (\sin x)^{\sin x} \Rightarrow \ln y = \sin x \ln \sin x \Rightarrow$$

$$\frac{y'}{y} = (\sin x) \left(\frac{\cos x}{\sin x} \right) + (\ln \sin x) \cos x = \cos x (1 + \ln \sin x) \Rightarrow y' = (\sin x)^{\sin x} (\cos x) (1 + \ln \sin x).$$

$$y' = 0 \Rightarrow \cos x = 0 \text{ or } \ln \sin x = -1 \Rightarrow x_2 = \frac{\pi}{2} \text{ or } \sin x = e^{-1}. \text{ On } (0, \pi), \sin x = e^{-1} \Rightarrow$$

$$x_1 = \sin^{-1}(e^{-1}) \text{ and } x_3 = \pi - \sin^{-1}(e^{-1}). \text{ Approximating these points gives us}$$

$$(x_1, f(x_1)) \approx (0.3767, 0.6922), (x_2, f(x_2)) \approx (1.5708, 1), \text{ and } (x_3, f(x_3)) \approx (2.7649, 0.6922). \text{ The}$$

approximations confirm our estimates.

From the graph, we see that $f''(x) = 0$ at $x \approx 0.94$ and $x \approx 2.20$. Since f'' changes sign at these values, they are x -coordinates of inflection points.

75. (a) $f(x) = x^{1/x}$

(b) Recall that $a^b = e^{b \ln a}$. $\lim_{x \rightarrow 0^+} x^{1/x} = \lim_{x \rightarrow 0^+} e^{(1/x) \ln x}$. As $x \rightarrow 0^+$,

$\frac{\ln x}{x} \rightarrow -\infty$, so $x^{1/x} = e^{(1/x) \ln x} \rightarrow 0$. This indicates that there is a hole at $(0, 0)$. As $x \rightarrow \infty$, we have the indeterminate form ∞^0 .

$\lim_{x \rightarrow \infty} x^{1/x} = \lim_{x \rightarrow \infty} e^{(1/x) \ln x}$, but $\lim_{x \rightarrow \infty} \frac{\ln x}{x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{1/x}{1} = 0$, so $\lim_{x \rightarrow \infty} x^{1/x} = e^0 = 1$. This indicates that $y = 1$ is a HA.

(c) Estimated maximum: $(2.72, 1.45)$. No estimated minimum. We use logarithmic differentiation to find any

critical numbers. $y = x^{1/x} \Rightarrow \ln y = \frac{1}{x} \ln x \Rightarrow \frac{y'}{y} = \frac{1}{x} \cdot \frac{1}{x} + (\ln x) \left(-\frac{1}{x^2} \right) \Rightarrow$

$y' = x^{1/x} \left(\frac{1 - \ln x}{x^2} \right) = 0 \Rightarrow \ln x = 1 \Rightarrow x = e$. For $0 < x < e$, $y' > 0$ and for $x > e$, $y' < 0$, so

$f(e) = e^{1/e}$ is a local maximum value. This point is approximately $(2.7183, 1.4447)$, which agrees with our estimate.

From the graph, we see that $f''(x) = 0$ at $x \approx 0.58$ and $x \approx 4.37$.

Since f'' changes sign at these values, they are x -coordinates of inflection points.

76.

The first figure shows representative examples of $f(x) = x^n e^{-x}$ with n odd. n is even in the second figure. All curves pass through the origin and approach $y = 0$ as $x \rightarrow \infty$. $f'(x) = \frac{x^n(n-x)}{x e^x} = 0 \Leftrightarrow x = n$ or $x = 0$ (the latter for $n > 1$). At $x = 0$, we have a local minimum for n even. At $x = n$, we have a local maximum for

all n . As n increases, $(n, f(n))$ gets farther away from the origin. $f''(x) = \frac{x^n(x^2 - 2nx + n^2 - n)}{x^2 e^x} = 0 \Leftrightarrow x = n \pm \sqrt{n}$ or $x = 0$ (the latter for $n > 2$). As n increases, the IP move farther away from the origin—they are symmetric about the line $x = n$.

77. If $c < 0$, then $\lim_{x \rightarrow -\infty} f(x) = \lim_{x \rightarrow -\infty} \frac{x}{e^{cx}} \stackrel{H}{=} \lim_{x \rightarrow -\infty} \frac{1}{ce^{cx}} = 0$, and $\lim_{x \rightarrow \infty} f(x) = \infty$.

If $c > 0$, then $\lim_{x \rightarrow -\infty} f(x) = -\infty$, and $\lim_{x \rightarrow \infty} f(x) \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{1}{ce^{cx}} = 0$.

If $c = 0$, then $f(x) = x$, so $\lim_{x \rightarrow \pm\infty} f(x) = \pm\infty$ respectively.

So we see that $c = 0$ is a transitional value. We now exclude the case $c = 0$, since we know how the function behaves in that case. To find the maxima and minima of f , we differentiate: $f(x) = xe^{-cx} \Rightarrow$

$f'(x) = x(-ce^{-cx}) + e^{-cx} = (1 - cx)e^{-cx}$. This is 0 when $1 - cx = 0 \Leftrightarrow x = 1/c$. If $c < 0$ then this

represents a minimum value of $f(1/c) = 1/(ce)$, since $f'(x)$ changes from negative to positive at $x = 1/c$;

and if $c > 0$, it represents a maximum value. As $|c|$ increases, the

maximum or minimum point gets closer to the origin. To find the inflection

points, we differentiate again: $f'(x) = e^{-cx}(1 - cx) \Rightarrow$

$f''(x) = e^{-cx}(-c) + (1 - cx)(-ce^{-cx}) = (cx - 2)ce^{-cx}$. This

changes sign when $cx - 2 = 0 \Leftrightarrow x = 2/c$. So as $|c|$ increases, the

points of inflection get closer to the origin.

78. We see that both numerator and denominator approach 0, so we can use l'Hospital's Rule:

$$\begin{aligned} \lim_{x \rightarrow a} \frac{\sqrt{2a^3x - x^4} - a\sqrt[3]{aax}}{a - \sqrt[4]{ax^3}} &\stackrel{H}{=} \lim_{x \rightarrow a} \frac{\frac{1}{2}(2a^3x - x^4)^{-1/2}(2a^3 - 4x^3) - a(\frac{1}{3})(aax)^{-2/3}a^2}{-\frac{1}{4}(ax^3)^{-3/4}(3ax^2)} \\ &= \frac{\frac{1}{2}(2a^3a - a^4)^{-1/2}(2a^3 - 4a^3) - \frac{1}{3}a^3(a^2a)^{-2/3}}{-\frac{1}{4}(aa^3)^{-3/4}(3aa^2)} \\ &= \frac{(a^4)^{-1/2}(-a^3) - \frac{1}{3}a^3(a^3)^{-2/3}}{-\frac{3}{4}a^3(a^4)^{-3/4}} = \frac{-a - \frac{1}{3}a}{-\frac{3}{4}} = \frac{4}{3}\left(\frac{4}{3}a\right) = \frac{16}{9}a \end{aligned}$$

79. First we will find $\lim_{n \rightarrow \infty} \left(1 + \frac{i}{n}\right)^{nt}$, which is of the form 1^∞ . $y = \left(1 + \frac{i}{n}\right)^{nt} \Rightarrow \ln y = nt \ln\left(1 + \frac{i}{n}\right)$, so

$$\lim_{n \rightarrow \infty} \ln y = \lim_{n \rightarrow \infty} nt \ln\left(1 + \frac{i}{n}\right) = t \lim_{n \rightarrow \infty} \frac{\ln(1 + i/n)}{1/n} \stackrel{H}{=} t \lim_{n \rightarrow \infty} \frac{(-i/n^2)}{(1 + i/n)(-1/n^2)} = t \lim_{n \rightarrow \infty} \frac{i}{1 + i/n} = ti$$

$$\Rightarrow \lim_{n \rightarrow \infty} y = e^{it}. \text{ Thus, as } n \rightarrow \infty, A = A_0 \left(1 + \frac{i}{n}\right)^{nt} \rightarrow A_0 e^{it}.$$

$$\begin{aligned} 80. (a) \lim_{t \rightarrow \infty} v &= \lim_{t \rightarrow \infty} \frac{mg}{c} (1 - e^{-ct/m}) = \frac{mg}{c} \lim_{t \rightarrow \infty} (1 - e^{-ct/m}) \\ &= \frac{mg}{c} (1 - 0) \quad [\text{because } -ct/m \rightarrow -\infty \text{ as } t \rightarrow \infty] = \frac{mg}{c}, \end{aligned}$$

which is the speed the object approaches as time goes on, the so-called limiting velocity.

$$\begin{aligned} (b) \lim_{m \rightarrow \infty} v &= \lim_{m \rightarrow \infty} \frac{mg}{c} (1 - e^{-ct/m}) = \frac{g}{c} \lim_{m \rightarrow \infty} \frac{1 - e^{-ct/m}}{1/m} \stackrel{H}{=} \frac{g}{c} \lim_{m \rightarrow \infty} \frac{-e^{-ct/m}(ct/m^2)}{-1/m^2} \\ &= \frac{g}{c} (ct) \lim_{m \rightarrow \infty} e^{-ct/m} = gt(1) \quad [\text{because } -ct/m \rightarrow 0 \text{ as } m \rightarrow \infty] = gt. \end{aligned}$$

The speed of a very heavy falling object is approximately proportional to the elapsed time t , provided it can fall

for time t in an environment where the given model continues to hold. [If t is too large, the object may hit the ground in less than time t , or it may have to start falling too high above the earth, where there is almost no air.]

81. Both numerator and denominator approach 0 as $x \rightarrow 0$, so we use l'Hospital's Rule (and FTC1):

$$\lim_{x \rightarrow 0} \frac{S(x)}{x^3} = \lim_{x \rightarrow 0} \frac{\int_0^x \sin(\pi t^2/2) dt}{x^3} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\sin(\pi x^2/2)}{3x^2} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\pi x \cos(\pi x^2/2)}{6x} = \frac{\pi}{6} \cdot \cos 0 = \frac{\pi}{6}$$

82. Both numerator and denominator approach 0 as $a \rightarrow 0$, so we use l'Hospital's Rule. (Note that we are differentiating with respect to a , since that is the quantity which is changing.) We also use the Fundamental Theorem of Calculus, Part 1:

$$\lim_{a \rightarrow 0} T(x, t) = \lim_{a \rightarrow 0} \frac{C \int_0^a e^{-(x-u)^2/(4kt)} du}{a \sqrt{4\pi kt}} \stackrel{H}{=} \lim_{a \rightarrow 0} \frac{C e^{-(x-a)^2/(4kt)}}{\sqrt{4\pi kt}} = \frac{C e^{-x^2/(4kt)}}{\sqrt{4\pi kt}}$$

83. Since $f(2) = 0$, the given limit has the form $\frac{0}{0}$.

$$\lim_{x \rightarrow 0} \frac{f(2+3x) + f(2+5x)}{x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{f'(2+3x) \cdot 3 + f'(2+5x) \cdot 5}{1} = f'(2) \cdot 3 + f'(2) \cdot 5 = 8f'(2) = 8 \cdot 7 = 56$$

84. $L = \lim_{x \rightarrow 0} \left(\frac{\sin 2x}{x^3} + a + \frac{b}{x^2} \right) = \lim_{x \rightarrow 0} \frac{\sin 2x + ax^3 + bx}{x^3} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{2 \cos 2x + 3ax^2 + b}{3x^2}$. As $x \rightarrow 0$, $3x^2 \rightarrow 0$, and $(2 \cos 2x + 3ax^2 + b) \rightarrow b + 2$, so the last limit exists only if $b + 2 = 0$, that is, $b = -2$. Thus,

$$\lim_{x \rightarrow 0} \frac{2 \cos 2x + 3ax^2 - 2}{3x^2} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{-4 \sin 2x + 6ax}{6x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{-8 \cos 2x + 6a}{6} = \frac{6a - 8}{6}, \text{ which is equal to 0 if and only if } a = \frac{4}{3}. \text{ Hence, } L = 0 \text{ if and only if } b = -2 \text{ and } a = \frac{4}{3}.$$

85. Since $\lim_{h \rightarrow 0} [f(x+h) - f(x-h)] = f(x) - f(x) = 0$ (f is differentiable and hence continuous) and $\lim_{h \rightarrow 0} 2h = 0$, we use l'Hospital's Rule:

$$\lim_{h \rightarrow 0} \frac{f(x+h) - f(x-h)}{2h} \stackrel{H}{=} \lim_{h \rightarrow 0} \frac{f'(x+h)(1) - f'(x-h)(-1)}{2} = \frac{f'(x) + f'(x)}{2} = \frac{2f'(x)}{2} = f'(x)$$

$\frac{f(x+h) - f(x-h)}{2h}$ is the slope of the secant line between $(x-h, f(x-h))$ and $(x+h, f(x+h))$. As $h \rightarrow 0$, this line gets closer to the tangent line and its slope approaches $f'(x)$.

86. Since $\lim_{h \rightarrow 0} [f(x+h) - 2f(x) + f(x-h)] = f(x) - 2f(x) + f(x) = 0$ (f is differentiable and hence continuous) and $\lim_{h \rightarrow 0} h^2 = 0$, we can apply l'Hospital's Rule:

$$\lim_{h \rightarrow 0} \frac{f(x+h) - 2f(x) + f(x-h)}{h^2} \stackrel{H}{=} \lim_{h \rightarrow 0} \frac{f'(x+h) - f'(x-h)}{2h} = f''(x)$$

At the last step, we have applied the result of Exercise 85 to $f'(x)$.

$$87. \lim_{x \rightarrow \infty} \frac{e^x}{x^n} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{nx^{n-1}} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{n(n-1)x^{n-2}} \stackrel{H}{=} \dots \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{e^x}{n!} = \infty$$

$$88. \lim_{x \rightarrow \infty} \frac{\ln x}{x^p} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{1/x}{px^{p-1}} = \lim_{x \rightarrow \infty} \frac{1}{px^p} = 0 \text{ since } p > 0.$$

$$89. \lim_{x \rightarrow 0^+} x^\alpha \ln x = \lim_{x \rightarrow 0^+} \frac{\ln x}{x^{-\alpha}} \stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{1/x}{-\alpha x^{-\alpha-1}} = \lim_{x \rightarrow 0^+} \frac{x^\alpha}{-\alpha} = 0 \text{ since } \alpha > 0.$$

90. Using l'Hospital's Rule and FTC1, we have

$$\lim_{x \rightarrow 0} \frac{\int_0^x \sin(t^2) dt}{x^3} = \lim_{x \rightarrow 0} \frac{\frac{d}{dx} \int_0^x \sin(t^2) dt}{3x^2} = \lim_{x \rightarrow 0} \frac{\sin(x^2)}{3x^2} = \frac{1}{3} \lim_{x \rightarrow 0} \frac{\sin(x^2)}{x^2} = \frac{1}{3}$$

91. Let the radius of the circle be r . We see that $A(\theta)$ is the area of the whole figure (a sector of the circle with radius 1), minus the area of $\triangle OPR$. But the area of the sector of the circle is $\frac{1}{2}r^2\theta$ (see Reference Page 1), and the area of the triangle is $\frac{1}{2}r|PQ| = \frac{1}{2}r(r \sin \theta) = \frac{1}{2}r^2 \sin \theta$. So we have

$$A(\theta) = \frac{1}{2}r^2\theta - \frac{1}{2}r^2 \sin \theta = \frac{1}{2}r^2(\theta - \sin \theta). \text{ Now by elementary trigonometry,}$$

$$B(\theta) = \frac{1}{2}|QR||PQ| = \frac{1}{2}(r - |OQ|)|PQ| = \frac{1}{2}(r - r \cos \theta)(r \sin \theta) = \frac{1}{2}r^2(1 - \cos \theta) \sin \theta.$$

So the limit we want is

$$\begin{aligned} \lim_{\theta \rightarrow 0^+} \frac{A(\theta)}{B(\theta)} &= \lim_{\theta \rightarrow 0^+} \frac{\frac{1}{2}r^2(\theta - \sin \theta)}{\frac{1}{2}r^2(1 - \cos \theta) \sin \theta} \stackrel{H}{=} \lim_{\theta \rightarrow 0^+} \frac{1 - \cos \theta}{(1 - \cos \theta) \cos \theta + \sin \theta (\sin \theta)} \\ &= \lim_{\theta \rightarrow 0^+} \frac{1 - \cos \theta}{\cos \theta - \cos^2 \theta + \sin^2 \theta} \stackrel{H}{=} \lim_{\theta \rightarrow 0^+} \frac{\sin \theta}{-\sin \theta - 2 \cos \theta (-\sin \theta) + 2 \sin \theta (\cos \theta)} \\ &= \lim_{\theta \rightarrow 0^+} \frac{\sin \theta}{-\sin \theta + 4 \sin \theta \cos \theta} = \lim_{\theta \rightarrow 0^+} \frac{1}{-1 + 4 \cos \theta} = \frac{1}{-1 + 4 \cos 0} = \frac{1}{3} \end{aligned}$$

92. The area $A(t) = \int_0^t \sin(x^2) dx$, and the area $B(t) = \frac{1}{2}t \sin(t^2)$. Since $\lim_{t \rightarrow 0^+} A(t) = 0 = \lim_{t \rightarrow 0^+} B(t)$, we can use l'Hospital's Rule:

$$\begin{aligned} \lim_{t \rightarrow 0^+} \frac{A(t)}{B(t)} &\stackrel{H}{=} \lim_{t \rightarrow 0^+} \frac{\sin(t^2)}{\frac{1}{2} \sin(t^2) + \frac{1}{2}t[2t \cos(t^2)]} \quad [\text{by FTC1 and the Product Rule}] \\ &\stackrel{H}{=} \lim_{t \rightarrow 0^+} \frac{2t \cos(t^2)}{t \cos(t^2) - 2t^3 \sin(t^2) + 2t \cos(t^2)} = \lim_{t \rightarrow 0^+} \frac{2 \cos(t^2)}{3 \cos(t^2) - 2t^2 \sin(t^2)} \\ &= \frac{2}{3 - 0} = \frac{2}{3} \end{aligned}$$

93. (a) We show that $\lim_{x \rightarrow 0} \frac{f(x)}{x^n} = 0$ for every integer $n \geq 0$. Let $y = \frac{1}{x^2}$. Then

$$\lim_{x \rightarrow 0} \frac{f(x)}{x^{2n}} = \lim_{x \rightarrow 0} \frac{e^{-1/x^2}}{(x^2)^n} = \lim_{y \rightarrow \infty} \frac{y^n}{e^y} \stackrel{H}{=} \lim_{y \rightarrow \infty} \frac{ny^{n-1}}{e^y} \stackrel{H}{=} \dots \stackrel{H}{=} \lim_{y \rightarrow \infty} \frac{n!}{e^y} = 0 \Rightarrow$$

$$\lim_{x \rightarrow 0} \frac{f(x)}{x^n} = \lim_{x \rightarrow 0} x^n \frac{f(x)}{x^{2n}} = \lim_{x \rightarrow 0} x^n \lim_{x \rightarrow 0} \frac{f(x)}{x^{2n}} = 0. \text{ Thus, } f'(0) = \lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x - 0} = \lim_{x \rightarrow 0} \frac{f(x)}{x} = 0.$$

- (b) Using the Chain Rule and the Quotient Rule we see that $f^{(n)}(x)$ exists for $x \neq 0$. In fact, we prove by induction that for each $n \geq 0$, there is a polynomial p_n and a non-negative integer k_n with $f^{(n)}(x) = p_n(x)f(x)/x^{k_n}$ for $x \neq 0$. This is true for $n = 0$; suppose it is true for the n th derivative. Then $f'(x) = f(x)(2/x^3)$, so

$$\begin{aligned} f^{(n+1)}(x) &= \left[x^{k_n} [p'_n(x)f(x) + p_n(x)f'(x)] - k_n x^{k_n-1} p_n(x)f(x) \right] x^{-2k_n} \\ &= \left[x^{k_n} p'_n(x) + p_n(x)(2/x^3) - k_n x^{k_n-1} p_n(x) \right] f(x) x^{-2k_n} \\ &= \left[x^{k_n+3} p'_n(x) + 2p_n(x) - k_n x^{k_n+2} p_n(x) \right] f(x) x^{-(2k_n+3)} \end{aligned}$$

which has the desired form.

Now we show by induction that $f^{(n)}(0) = 0$ for all n . By part (a), $f'(0) = 0$. Suppose that $f^{(n)}(0) = 0$. Then

$$\begin{aligned} f^{(n+1)}(0) &= \lim_{x \rightarrow 0} \frac{f^{(n)}(x) - f^{(n)}(0)}{x - 0} = \lim_{x \rightarrow 0} \frac{f^{(n)}(x)}{x} = \lim_{x \rightarrow 0} \frac{p_n(x)f(x)/x^{k_n}}{x} = \lim_{x \rightarrow 0} \frac{p_n(x)f(x)}{x^{k_n+1}} \\ &= \lim_{x \rightarrow 0} p_n(x) \lim_{x \rightarrow 0} \frac{f(x)}{x^{k_n+1}} = p_n(0) \cdot 0 = 0 \end{aligned}$$

94. (a) For f to be continuous, we need $\lim_{x \rightarrow 0} f(x) = f(0) = 1$. We note that for $x \neq 0$, $\ln f(x) = \ln |x|^x = x \ln |x|$.

So $\lim_{x \rightarrow 0} \ln f(x) = \lim_{x \rightarrow 0} x \ln |x| = \lim_{x \rightarrow 0} \frac{\ln |x|}{1/x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{1/x}{-1/x^2} = 0$. Therefore,

$\lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} e^{\ln f(x)} = e^0 = 1$. So f is continuous at 0.

- (b) From the graphs, it appears that f is differentiable at 0.

- (c) To find f' , we use logarithmic differentiation: $\ln f(x) = x \ln |x| \Rightarrow \frac{f'(x)}{f(x)} = x \left(\frac{1}{x} \right) + \ln |x| \Rightarrow$

$f'(x) = f(x)(1 + \ln |x|) = |x|^x(1 + \ln |x|)$, $x \neq 0$. Now $f'(x) \rightarrow -\infty$ as $x \rightarrow 0$ [since $|x|^x \rightarrow 1$ and $(1 + \ln |x|) \rightarrow -\infty$], so the curve has a vertical tangent at $(0, 1)$ and is therefore not differentiable there. The fact cannot be seen in the graphs in part (b) because $\ln |x| \rightarrow -\infty$ very slowly as $x \rightarrow 0$.

7 Review

CONCEPT CHECK

1. (a) See Definition 1 in Section 7.1. It must pass the Horizontal Line Test.
 (b) See Definition 2 in Section 7.1. The graph of f^{-1} is obtained by reflecting the graph of f about the line $y = x$.
 (c) $g'(a) = (f^{-1})'(a) = \frac{1}{f'(g(a))}$
2. (a) The function $f(x) = e^x$ has domain $\mathbb{R}$ and range $(0, \infty)$.
 (b) The function $f(x) = \ln x$ has domain $(0, \infty)$ and range $\mathbb{R}$.
 (c) The graphs are reflections of one another about the line $y = x$. See Figure 7.3.3 or Figure 7.3*.1.
 (d) $\log_a x = \frac{\ln x}{\ln a}$
3. (a) See Definition 7.5.1. Domain = $[-1, 1]$, Range = $[-\frac{\pi}{2}, \frac{\pi}{2}]$
 (b) See Definition 7.5.4. Domain = $[-1, 1]$, Range = $[0, \pi]$
 (c) See Definition 7.5.7. Domain = $\mathbb{R}$, Range = $(-\frac{\pi}{2}, \frac{\pi}{2})$. See Figure 10 in Section 7.5.
4. $\sinh x = \frac{e^x - e^{-x}}{2}$, $\cosh x = \frac{e^x + e^{-x}}{2}$, $\tanh x = \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}}$
5. (a) $y = e^x \Rightarrow y' = e^x$
 (b) $y = a^x \Rightarrow y' = a^x \ln a$
 (c) $y = \ln x \Rightarrow y' = 1/x$
 (d) $y = \log_a x \Rightarrow y' = 1/(x \ln a)$
 (e) $y = \sin^{-1} x \Rightarrow y' = 1/\sqrt{1-x^2}$
 (f) $y = \cos^{-1} x \Rightarrow y' = -1/\sqrt{1-x^2}$
 (g) $y = \tan^{-1} x \Rightarrow y' = 1/(1+x^2)$
 (h) $y = \sinh x \Rightarrow y' = \cosh x$
 (i) $y = \cosh x \Rightarrow y' = \sinh x$
 (j) $y = \tanh x \Rightarrow y' = \operatorname{sech}^2 x$
 (k) $y = \sinh^{-1} x \Rightarrow y' = 1/\sqrt{1+x^2}$
 (l) $y = \cosh^{-1} x \Rightarrow y' = 1/\sqrt{x^2-1}$
 (m) $y = \tanh^{-1} x \Rightarrow y' = 1/(1-x^2)$
6. (a) e is the number such that $\lim_{h \rightarrow 0} \frac{e^h - 1}{h} = 1$.
 (b) $e = \lim_{x \rightarrow 0} (1+x)^{1/x}$
 (c) The differentiation formula for $y = a^x$ [$y' = a^x \ln a$] is simplest when $a = e$ because $\ln e = 1$.
 (d) The differentiation formula for $y = \log_a x$ [$y' = 1/(x \ln a)$] is simplest when $a = e$ because $\ln e = 1$.
7. (a) See l'Hospital's Rule and the three notes that follow it in Section 7.7.
 (b) Write fg as $\frac{f}{1/g}$ or $\frac{g}{1/f}$.
 (c) Convert the difference into a quotient using a common denominator, rationalizing, factoring, or some other method.
 (d) Convert the power to a product by taking the natural logarithm of both sides of $y = f^g$ or by writing f^g as $e^{g \ln f}$.

TRUE-FALSE QUIZ

- True. If f is one-to-one, with domain $\mathbb{R}$, then $f^{-1}(f(6)) = 6$ by the first cancellation equation [see (4) in Section 7.1].
- False. By Theorem 7 in Section 7.1, $(f^{-1})'(6) = \frac{1}{f'(f^{-1}(6))}$, *not* $\frac{1}{f'(6)}$ unless $f^{-1}(6) = 6$.
- False. For example, $\cos \frac{\pi}{2} = \cos(-\frac{\pi}{2})$, so $\cos x$ is not 1-1.
- False. It is true that $\tan \frac{3\pi}{4} = -1$, but since the range of $\tan^{-1}$ is $(-\frac{\pi}{2}, \frac{\pi}{2})$, we must have $\tan^{-1}(-1) = -\frac{\pi}{4}$.
- True, since $\ln x$ is an increasing function on $(0, \infty)$.
- True, by Equation 7.4*.1.
- True. We can divide by e^x since $e^x \neq 0$ for every x .
- False. For example, $\ln(1+1) = \ln 2$, but $\ln 1 + \ln 1 = 0$. In fact $\ln a + \ln b = \ln(ab)$.
- False. Let $x = e$. Then $(\ln x)^6 = (\ln e)^6 = 1^6 = 1$, but $6 \ln x = 6 \ln e = 6 \cdot 1 = 6 \neq 1 = (\ln x)^6$.
- False. $\frac{d}{dx} 10^x = 10^x \ln 10$
- False. $\ln 10$ is a constant, so its derivative is 0.
- True. $y = e^{3x} \Rightarrow \ln y = 3x \Rightarrow x = \frac{1}{3} \ln y \Rightarrow$ the inverse function is $y = \frac{1}{3} \ln x$.
- False. The “-1” is not an exponent; it is an indication of an inverse function.
- False. For example, $\tan^{-1} 20$ is defined; $\sin^{-1} 20$ and $\cos^{-1} 20$ are not.
- True. See Figure 2 in Section 7.6.
- True. $\ln \frac{1}{10} = -\ln 10 = -\int_1^{10} (1/x) dx$, by Equation 7.4.4 or by Definition 7.2*.1.
- True. $\int_2^{16} (1/x) dx = \ln x \Big|_2^{16} = \ln 16 - \ln 2 = \ln \frac{16}{2} = \ln 8 = \ln 2^3 = 3 \ln 2$
- False. L'Hospital's Rule does not apply since $\lim_{x \rightarrow \pi^-} \frac{\tan x}{1 - \cos x} = \frac{0}{2} = 0$.

EXERCISES

- No. f is not 1-1 because the graph of f fails the Horizontal Line Test.
- g is one-to-one because it passes the Horizontal Line Test.
 - When $y = 2$, $x \approx 0.2$. So $g^{-1}(2) \approx 0.2$.
 - The range of g is $[-1, 3.5]$, which is the same as the domain of g^{-1} .
 - We reflect the graph of g through the line $y = x$ to obtain the graph of g^{-1} .

3. (a) $f^{-1}(3) = 7$ since $f(7) = 3$.

(b) $(f^{-1})'(3) = \frac{1}{f'(f^{-1}(3))} = \frac{1}{f'(7)} = \frac{1}{8}$

4. $y = \frac{x+1}{2x+1}$. Interchanging x and y gives us $x = \frac{y+1}{2y+1} \Rightarrow 2xy + x = y + 1 \Rightarrow 2xy - y = 1 - x \Rightarrow$
 $y(2x - 1) = 1 - x \Rightarrow y = \frac{1-x}{2x-1} = f^{-1}(x).$

5. $y = 5^x - 1$

6. $y = e^{-x}$

$y = -e^{-x}$

7. Reflect the graph of $y = \ln x$ about the x -axis to obtain the graph of $y = -\ln x$.

$y = \ln x$

$y = -\ln x$

8. $y = \ln(x-1)$

9. $y = 2 \arctan x$

10. We have seen that if $a > 1$, then $a^x > x^a$ for sufficiently large x . (See Exercise 7.2.20.) In general, we could show that $\lim_{x \rightarrow \infty} (a^x/x^a) = \infty$ by using l'Hospital's Rule repeatedly. Also, $\log_a x$ increases much more slowly than either x^a or a^x . [Compare the graph of $\log_a x$ with those of x^a and a^x , or use l'Hospital's Rule to show that $\lim_{x \rightarrow \infty} [(\log_a x)/x^a] = 0$.] So for large x , $\log_a x < x^a < a^x$.

11. (a) $e^{2 \ln 3} = (e^{\ln 3})^2 = 3^2 = 9$

(b) $\log_{10} 25 + \log_{10} 4 = \log_{10}(25 \cdot 4) = \log_{10} 100 = \log_{10} 10^2 = 2$

12. (a) $\ln e^\pi = \pi$

(b) $\tan(\arcsin \frac{1}{2}) = \tan \frac{\pi}{6} = \frac{1}{\sqrt{3}}$

13. $\ln x = \frac{1}{3} \Leftrightarrow \log_e x = \frac{1}{3} \Rightarrow x = e^{1/3}$
14. $e^x = \frac{1}{3} \Rightarrow x = \ln \frac{1}{3} = \ln 1 - \ln 3 = -\ln 3$
15. $e^{e^x} = 17 \Rightarrow \ln e^{e^x} = \ln 17 \Rightarrow e^x = \ln 17 \Rightarrow \ln e^x = \ln(\ln 17) \Rightarrow x = \ln \ln 17$
16. $\ln(1 + e^{-x}) = 3 \Rightarrow 1 + e^{-x} = e^3 \Rightarrow e^{-x} = e^3 - 1 \Rightarrow \ln e^{-x} = \ln(e^3 - 1) \Rightarrow -x = \ln(e^3 - 1) \Rightarrow x = -\ln(e^3 - 1)$
17. $\ln(x+1) + \ln(x-1) = 1 \Rightarrow \ln[(x+1)(x-1)] = 1 \Rightarrow \ln(x^2 - 1) = \ln e \Rightarrow x^2 - 1 = e \Rightarrow x^2 = e + 1 \Rightarrow x = \sqrt{e+1}$ since $\ln(x-1)$ is defined only when $x > 1$.
18. $\log_5(c^x) = d \Rightarrow x \log_5 c = d \Rightarrow x = \frac{d}{\log_5 c}$.
 Or: $\log_5(c^x) = d \Rightarrow 5^d = c^x \Rightarrow \ln 5^d = \ln c^x \Rightarrow d \ln 5 = x \ln c \Rightarrow x = \frac{d \ln 5}{\ln c}$.
19. $\tan^{-1} x = 1 \Rightarrow \tan \tan^{-1} x = \tan 1 \Rightarrow x = \tan 1 (\approx 1.5574)$
20. $\sin x = 0.3 \Rightarrow x = \sin^{-1} 0.3 = \alpha$ for $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$. The reference angle for α is $\pi - \alpha$, so all solutions are $x = \alpha + 2n\pi$ and $x = \pi - \alpha + 2n\pi$ [or $(2n+1)\pi - \alpha$]
21. $f(t) = t^2 \ln t \Rightarrow f'(t) = t^2 \cdot \frac{1}{t} + (\ln t)(2t) = t + 2t \ln t$ or $t(1 + 2 \ln t)$
22. $g(t) = \frac{e^t}{1 + e^t} \Rightarrow g'(t) = \frac{(1 + e^t)e^t - e^t(e^t)}{(1 + e^t)^2} = \frac{e^t}{(1 + e^t)^2}$
23. $h(\theta) = e^{\tan 2\theta} \Rightarrow h'(\theta) = e^{\tan 2\theta} \cdot \sec^2 2\theta \cdot 2 = 2 \sec^2 2\theta e^{\tan 2\theta}$
24. $h(u) = 10^{\sqrt{u}} \Rightarrow h'(u) = 10^{\sqrt{u}} \cdot \ln 10 \cdot \frac{1}{2\sqrt{u}} = \frac{(\ln 10)10^{\sqrt{u}}}{2\sqrt{u}}$
25. $y = \ln |\sec 5x + \tan 5x| \Rightarrow$
 $y' = \frac{1}{\sec 5x + \tan 5x} (\sec 5x \tan 5x \cdot 5 + \sec^2 5x \cdot 5) = \frac{5 \sec 5x (\tan 5x + \sec 5x)}{\sec 5x + \tan 5x} = 5 \sec 5x$
26. $y = e^{-t}(t^2 - 2t + 2) \Rightarrow$
 $y' = e^{-t}(2t - 2) + (t^2 - 2t + 2)(-e^{-t}) = e^{-t}(2t - 2 - t^2 + 2t - 2) = e^{-t}(-t^2 + 4t - 4)$
27. $y = e^{cx}(c \sin x - \cos x) \Rightarrow y' = ce^{cx}(c \sin x - \cos x) + e^{cx}(c \cos x + \sin x) = (c^2 + 1)e^{cx} \sin x$
28. $y = \sin^{-1}(e^x) \Rightarrow y' = 1/\sqrt{1 - (e^x)^2} \cdot e^x = e^x/\sqrt{1 - e^{2x}}$
29. $y = \ln(\sec^2 x) = 2 \ln |\sec x| \Rightarrow y' = (2/\sec x)(\sec x \tan x) = 2 \tan x$
30. $y = \ln(x^2 e^x) = 2 \ln |x| + x \Rightarrow y' = 2/x + 1$
31. $y = xe^{-1/x} \Rightarrow y' = e^{-1/x} + xe^{-1/x}(1/x^2) = e^{-1/x}(1 + 1/x)$
32. $y = x^r e^{sx} \Rightarrow y' = rx^{r-1} e^{sx} + sx^r e^{sx}$
33. $y = 2^{-t^2} \Rightarrow y' = 2^{-t^2}(\ln 2)(-2t) = (-2 \ln 2)t 2^{-t^2}$
34. $y = e^{\cos x} + \cos(e^x) \Rightarrow y' = -\sin x e^{\cos x} - e^x \sin(e^x)$
35. $H(v) = v \tan^{-1} v \Rightarrow H'(v) = v \cdot \frac{1}{1+v^2} + \tan^{-1} v \cdot 1 = \frac{v}{1+v^2} + \tan^{-1} v$
36. $F(z) = \log_{10}(1+z^2) \Rightarrow F'(z) = \frac{1}{(\ln 10)(1+z^2)} \cdot 2z = \frac{2z}{(\ln 10)(1+z^2)}$
37. $y = x \sinh(x^2) \Rightarrow y' = x \cosh(x^2) \cdot 2x + \sinh(x^2) \cdot 1 = 2x^2 \cosh(x^2) + \sinh(x^2)$

$$38. y = (\cos x)^x \Rightarrow \ln y = \ln(\cos x)^x = x \ln \cos x \Rightarrow \frac{y'}{y} = x \cdot \frac{1}{\cos x} \cdot (-\sin x) + \ln \cos x \cdot 1 \Rightarrow$$

$$y' = (\cos x)^x (\ln \cos x - x \tan x)$$

$$39. y = \ln \sin x - \frac{1}{2} \sin^2 x \Rightarrow y' = \frac{1}{\sin x} \cdot \cos x - \frac{1}{2} \cdot 2 \sin x \cdot \cos x = \cot x - \sin x \cos x$$

$$40. y = \arctan(\arcsin \sqrt{x}) \Rightarrow y' = \frac{1}{1 + (\arcsin \sqrt{x})^2} \cdot \frac{1}{\sqrt{1-x}} \cdot \frac{1}{2\sqrt{x}}$$

$$41. y = \ln \frac{1}{x} + \frac{1}{\ln x} = \ln x^{-1} + (\ln x)^{-1} = -\ln x + (\ln x)^{-1} \Rightarrow$$

$$y' = -1 \cdot \frac{1}{x} + (-1)(\ln x)^{-2} \cdot \frac{1}{x} = -\frac{1}{x} - \frac{1}{x(\ln x)^2}$$

$$42. xe^y = y - 1 \Rightarrow e^y + xe^y y' = y' \Rightarrow y' = e^y / (1 - xe^y)$$

$$43. y = \ln(\cosh 3x) \Rightarrow y' = (1/\cosh 3x)(\sinh 3x)(3) = 3 \tanh 3x$$

$$44. y = \frac{(x^2 + 1)^4}{(2x + 1)^3(3x - 1)^5} \Rightarrow$$

$$\ln y = \ln \frac{(x^2 + 1)^4}{(2x + 1)^3(3x - 1)^5} = \ln(x^2 + 1)^4 - \ln[(2x + 1)^3(3x - 1)^5]$$

$$= 4 \ln(x^2 + 1) - [\ln(2x + 1)^3 + \ln(3x - 1)^5] = 4 \ln(x^2 + 1) - 3 \ln(2x + 1) - 5 \ln(3x - 1) \Rightarrow$$

$$\frac{y'}{y} = 4 \cdot \frac{1}{x^2 + 1} \cdot 2x - 3 \cdot \frac{1}{2x + 1} \cdot 2 - 5 \cdot \frac{1}{3x - 1} \cdot 3 \Rightarrow$$

$$y' = \frac{(x^2 + 1)^4}{(2x + 1)^3(3x - 1)^5} \left(\frac{8x}{x^2 + 1} - \frac{6}{2x + 1} - \frac{15}{3x - 1} \right).$$

[The answer could be simplified to $y' = -\frac{(x^2 + 56x + 9)(x^2 + 1)^3}{(2x + 1)^4(3x - 1)^6}$, but this is unnecessary.]

$$45. y = \cosh^{-1}(\sinh x) \Rightarrow y' = (\cosh x) / \sqrt{\sinh^2 x - 1}$$

$$46. y = x \tanh^{-1} \sqrt{x} \Rightarrow y' = \tanh^{-1} \sqrt{x} + x \frac{1}{1 - (\sqrt{x})^2} \frac{1}{2\sqrt{x}} = \tanh^{-1} \sqrt{x} + \frac{\sqrt{x}}{2(1-x)}$$

$$47. f(x) = e^{\sin^3(\ln(x^2+1))} \Rightarrow$$

$$f'(x) = e^{\sin^3(\ln(x^2+1))} \cdot 3 \sin^2(\ln(x^2+1)) \cdot \cos(\ln(x^2+1)) \cdot \frac{1}{x^2+1} \cdot 2x$$

$$= \frac{6x}{x^2+1} \sin^2(\ln(x^2+1)) \cdot \cos(\ln(x^2+1)) \cdot e^{\sin^3(\ln(x^2+1))}$$

$$48. \frac{d}{dx} \left(\frac{1}{2} \tan^{-1} x + \frac{1}{4} \ln \frac{(x+1)^2}{x^2+1} \right) = \frac{d}{dx} \left(\frac{1}{2} \tan^{-1} x + \frac{1}{2} \ln |x+1| - \frac{1}{4} \ln(x^2+1) \right)$$

$$= \frac{1}{2} \frac{1}{x^2+1} + \frac{1}{2} \frac{1}{x+1} - \frac{1}{4} \frac{2x}{x^2+1} = \frac{1}{2} \left(\frac{1}{x^2+1} - \frac{x}{x^2+1} + \frac{1}{x+1} \right)$$

$$= \frac{1}{2} \left(\frac{1-x}{x^2+1} + \frac{1}{x+1} \right) = \frac{1}{2} \left(\frac{1-x^2}{(x^2+1)(1+x)} + \frac{x^2+1}{(x^2+1)(1+x)} \right)$$

$$= \frac{1}{2} \frac{2}{(x^2+1)(1+x)} = \frac{1}{(1+x)(x^2+1)}$$

$$49. f(x) = e^{g(x)} \Rightarrow f'(x) = e^{g(x)} g'(x)$$

$$50. f(x) = g(e^x) \Rightarrow f'(x) = g'(e^x) e^x$$

$$51. f(x) = \ln |g(x)| \Rightarrow f'(x) = \frac{1}{g(x)} g'(x) = \frac{g'(x)}{g(x)}$$

$$52. f(x) = g(\ln x) \Rightarrow f'(x) = g'(\ln x) \cdot \frac{1}{x} = \frac{g'(\ln x)}{x}$$

$$53. f(x) = 2^x \Rightarrow f'(x) = 2^x \ln 2 \Rightarrow f''(x) = 2^x (\ln 2)^2 \Rightarrow \dots \Rightarrow f^{(n)}(x) = 2^x (\ln 2)^n$$

$$54. f(x) = \ln(2x) = \ln 2 + \ln x \Rightarrow f'(x) = x^{-1}, f''(x) = -x^{-2}, f'''(x) = 2x^{-3}, f^{(4)}(x) = -2 \cdot 3x^{-4}, \dots, \\ f^{(n)}(x) = (-1)^{n-1} (n-1)! x^{-n}$$

55. We first show it is true for $n = 1$: $f'(x) = e^x + xe^x = (x+1)e^x$. We now assume it is true for $n = k$:

$f^{(k)}(x) = (x+k)e^x$. With this assumption, we must show it is true for $n = k+1$:

$$f^{(k+1)}(x) = \frac{d}{dx} [f^{(k)}(x)] = \frac{d}{dx} [(x+k)e^x] = e^x + (x+k)e^x = [x+(k+1)]e^x.$$

Therefore, $f^{(n)}(x) = (x+n)e^x$ by mathematical induction.

$$56. \text{ Using implicit differentiation, } y = x + \arctan y \Rightarrow y' = 1 + \frac{1}{1+y^2} y' \Rightarrow y' \left(1 - \frac{1}{1+y^2} \right) = 1 \Rightarrow$$

$$y' \left(\frac{y^2}{1+y^2} \right) = 1 \Rightarrow y' = \frac{1+y^2}{y^2} = \frac{1}{y^2} + 1.$$

$$57. y = (2+x)e^{-x} \Rightarrow y' = (2+x)(-e^{-x}) + e^{-x} \cdot 1 = e^{-x}[-(2+x)+1] = e^{-x}(-x-1). \text{ At } (0, 2), \\ y' = 1(-1) = -1, \text{ so an equation of the tangent line is } y - 2 = -1(x - 0), \text{ or } y = -x + 2.$$

$$58. y = f(x) = x \ln x \Rightarrow f'(x) = \ln x + 1, \text{ so the slope of the tangent at } (e, e) \text{ is } f'(e) = 2 \text{ and an equation is} \\ y - e = 2(x - e) \text{ or } y = 2x - e.$$

$$59. y = [\ln(x+4)]^2 \Rightarrow y' = 2 \frac{\ln(x+4)}{x+4} = 0 \Leftrightarrow \ln(x+4) = 0 \Leftrightarrow x+4 = 1 \Leftrightarrow x = -3, \text{ so the} \\ \text{tangent is horizontal at } (-3, 0).$$

$$60. f(x) = xe^{\sin x} \Rightarrow f'(x) = x[e^{\sin x}(\cos x)] + e^{\sin x}(1) = e^{\sin x}(x \cos x + 1). \text{ As a check on our work, we} \\ \text{notice from the graphs that } f'(x) > 0 \text{ when } f \text{ is increasing. Also, we see in the larger viewing rectangle a certain} \\ \text{similarity in the graphs of } f \text{ and } f': \text{ the sizes of the oscillations of } f \text{ and } f' \text{ are linked.}$$

$$61. (a) \text{ The line } x - 4y = 1 \text{ has slope } \frac{1}{4}. \text{ The tangent to } y = e^x \text{ has slope } \frac{1}{4} \text{ when } y' = e^x = \frac{1}{4} \Rightarrow \\ x = \ln \frac{1}{4} = -\ln 4, \text{ so an equation is } y - \frac{1}{4} = \frac{1}{4}(x + \ln 4) \text{ or } y = \frac{1}{4}x + \frac{1}{4}(\ln 4 + 1).$$

$$(b) \text{ The slope of the tangent at the point } (a, e^a) \text{ is } \left. \frac{d}{dx} e^x \right|_{x=a} = e^a. \text{ An equation of the tangent line is thus}$$

$$y - e^a = e^a(x - a). \text{ We substitute } x = 0, y = 0 \text{ into this equation, since we want the line to pass through the} \\ \text{origin: } 0 - e^a = e^a(0 - a) \Leftrightarrow -e^a = e^a(-a) \Leftrightarrow a = 1. \text{ So an equation of the tangent is} \\ y - e = e(x - 1), \text{ or } y = ex.$$

$$62. (a) \lim_{t \rightarrow \infty} C(t) = \lim_{t \rightarrow \infty} [K(e^{-at} - e^{-bt})] = K \lim_{t \rightarrow \infty} (e^{-at} - e^{-bt}) = K(0 - 0) = 0 \text{ because } -at \rightarrow -\infty \text{ and } -bt \rightarrow -\infty \text{ as } t \rightarrow \infty.$$

$$(b) C(t) = K(e^{-at} - e^{-bt}) \Rightarrow C'(t) = K(e^{-at}(-a) - e^{-bt}(-b)) = K(-ae^{-at} + be^{-bt})$$

$$(c) C'(t) = 0 \Rightarrow be^{-bt} = ae^{-at} \Rightarrow \frac{b}{a} = e^{(-a+b)t} \Rightarrow \ln \frac{b}{a} = (b-a)t \Rightarrow t = \frac{\ln(b/a)}{b-a}$$

$$63. \lim_{x \rightarrow \infty} e^{-3x} = 0 \text{ since } -3x \rightarrow -\infty \text{ as } x \rightarrow \infty \text{ and } \lim_{t \rightarrow -\infty} e^t = 0.$$

$$64. \lim_{x \rightarrow 10^-} \ln(100 - x^2) = -\infty \text{ since as } x \rightarrow 10^-, (100 - x^2) \rightarrow 0^+.$$

$$65. \text{ Let } t = 2/(x-3). \text{ As } x \rightarrow 3^-, t \rightarrow -\infty. \lim_{x \rightarrow 3^-} e^{2/(x-3)} = \lim_{t \rightarrow -\infty} e^t = 0$$

$$66. \text{ If } y = x^3 - x = x(x^2 - 1), \text{ then as } x \rightarrow \infty, y \rightarrow \infty. \lim_{x \rightarrow \infty} \arctan(x^3 - x) = \lim_{y \rightarrow \infty} \arctan y = \frac{\pi}{2} \text{ by (7.5.8).}$$

$$67. \text{ Let } t = \sinh x. \text{ As } x \rightarrow 0^+, t \rightarrow 0^+. \lim_{x \rightarrow 0^+} \ln(\sinh x) = \lim_{t \rightarrow 0^+} \ln t = -\infty$$

$$68. -1 \leq \sin x \leq 1 \Rightarrow -e^{-x} \leq e^{-x} \sin x \leq e^{-x}. \text{ Now } \lim_{x \rightarrow \infty} (\pm e^{-x}) = 0, \text{ so by the Squeeze Theorem,}$$

$$\lim_{x \rightarrow \infty} e^{-x} \sin x = 0.$$

$$69. \lim_{x \rightarrow \infty} \frac{(1 + 2^x)/2^x}{(1 - 2^x)/2^x} = \lim_{x \rightarrow \infty} \frac{1/2^x + 1}{1/2^x - 1} = \frac{0 + 1}{0 - 1} = -1$$

$$70. \text{ Let } t = x/4, \text{ so } x = 4t. \text{ As } x \rightarrow \infty, t \rightarrow \infty. \lim_{x \rightarrow \infty} \left(1 + \frac{4}{x}\right)^x = \lim_{t \rightarrow \infty} \left(1 + \frac{1}{t}\right)^{4t} = \left[\lim_{t \rightarrow \infty} \left(1 + \frac{1}{t}\right)^t \right]^4 = e^4$$

$$71. \lim_{x \rightarrow 0} \frac{\tan \pi x}{\ln(1+x)} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\pi \sec^2 \pi x}{1/(1+x)} = \frac{\pi \cdot 1^2}{1/1} = \pi$$

$$72. \lim_{x \rightarrow 0} \frac{1 - \cos x}{x^2 + x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{\sin x}{2x + 1} = \frac{0}{1} = 0$$

$$73. \lim_{x \rightarrow 0} \frac{e^{4x} - 1 - 4x}{x^2} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{4e^{4x} - 4}{2x} \stackrel{H}{=} \lim_{x \rightarrow 0} \frac{16e^{4x}}{2} = \lim_{x \rightarrow 0} 8e^{4x} = 8 \cdot 1 = 8$$

$$74. \lim_{x \rightarrow \infty} \frac{e^{4x} - 1 - 4x}{x^2} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{4e^{4x} - 4}{2x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{16e^{4x}}{2} = \lim_{x \rightarrow \infty} 8e^{4x} = \infty$$

$$75. \lim_{x \rightarrow \infty} x^3 e^{-x} = \lim_{x \rightarrow \infty} \frac{x^3}{e^x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{3x^2}{e^x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{6x}{e^x} \stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{6}{e^x} = 0$$

$$76. \lim_{x \rightarrow 0^+} x^2 \ln x = \lim_{x \rightarrow 0^+} \frac{\ln x}{1/x^2} \stackrel{H}{=} \lim_{x \rightarrow 0^+} \frac{1/x}{-2/x^3} = \lim_{x \rightarrow 0^+} \left(-\frac{1}{2}x^2\right) = 0$$

$$\begin{aligned} 77. \lim_{x \rightarrow 1^+} \left(\frac{x}{x-1} - \frac{1}{\ln x} \right) &= \lim_{x \rightarrow 1^+} \left(\frac{x \ln x - x + 1}{(x-1) \ln x} \right) \stackrel{H}{=} \lim_{x \rightarrow 1^+} \frac{x \cdot (1/x) + \ln x - 1}{(x-1) \cdot (1/x) + \ln x} \\ &= \lim_{x \rightarrow 1^+} \frac{\ln x}{1 - 1/x + \ln x} \stackrel{H}{=} \lim_{x \rightarrow 1^+} \frac{1/x}{1/x^2 + 1/x} = \frac{1}{1+1} = \frac{1}{2} \end{aligned}$$

78. $y = (\tan x)^{\cos x} \Rightarrow \ln y = \cos x \ln \tan x$, so

$$\begin{aligned}\lim_{x \rightarrow (\pi/2)^-} \ln y &= \lim_{x \rightarrow (\pi/2)^-} \frac{\ln \tan x}{\sec x} \stackrel{H}{=} \lim_{x \rightarrow (\pi/2)^-} \frac{(1/\tan x) \sec^2 x}{\sec x \tan x} = \lim_{x \rightarrow (\pi/2)^-} \frac{\sec x}{\tan^2 x} \\ &= \lim_{x \rightarrow (\pi/2)^-} \frac{\cos x}{\sin^2 x} = \frac{0}{1^2} = 0, \text{ so}\end{aligned}$$

$$\lim_{x \rightarrow (\pi/2)^-} (\tan x)^{\cos x} = \lim_{x \rightarrow (\pi/2)^-} e^{\ln y} = e^0 = 1.$$

79. $y = f(x) = \tan^{-1}(1/x)$ **A.** $D = \{x \mid x \neq 0\}$ **B.** No intercept **C.** $f(-x) = -f(x)$, so the curve is symmetric about the origin. **D.** $\lim_{x \rightarrow \pm\infty} \tan^{-1}(1/x) = \tan^{-1} 0 = 0$, so $y = 0$ is a HA. $\lim_{x \rightarrow 0^+} \tan^{-1}(1/x) = \frac{\pi}{2}$

and $\lim_{x \rightarrow 0^-} \tan^{-1}(1/x) = -\frac{\pi}{2}$ since $\frac{1}{x} \rightarrow \pm\infty$ as $x \rightarrow 0^\pm$.

E. $f'(x) = \frac{1}{1 + (1/x)^2} (-1/x^2) = \frac{-1}{x^2 + 1} \Rightarrow f'(x) < 0$,

so f is decreasing on $(-\infty, 0)$ and $(0, \infty)$. **F.** No maximum nor minimum

G. $f''(x) = \frac{2x}{(x^2 + 1)^2} > 0 \Leftrightarrow x > 0$, so f is CU on $(0, \infty)$ and CD on $(-\infty, 0)$.

H.

80. $y = f(x) = \sin^{-1}(1/x)$ **A.** $D = \{x \mid -1 \leq 1/x \leq 1\} = (-\infty, -1] \cup [1, \infty)$. **B.** No intercept

C. $f(-x) = -f(x)$, symmetric about the origin **D.** $\lim_{x \rightarrow \pm\infty} \sin^{-1}(1/x) = \sin^{-1}(0) = 0$, so $y = 0$ is a HA.

E. $f'(x) = \frac{1}{\sqrt{1 - (1/x)^2}} \left(-\frac{1}{x^2}\right) = \frac{-1}{\sqrt{x^4 - x^2}} < 0$, so f is decreasing on $(-\infty, -1)$ and $(1, \infty)$.

F. No local extreme value, but $f(1) = \frac{\pi}{2}$ is the absolute maximum value and $f(-1) = -\frac{\pi}{2}$ is the absolute minimum value.

G. $f''(x) = \frac{4x^3 - 2x}{2(x^4 - x^2)^{3/2}} = \frac{x(2x^2 - 1)}{(x^4 - x^2)^{3/2}} > 0$ for $x > 1$ and

$f''(x) < 0$ for $x < -1$, so f is CU on $(1, \infty)$ and CD on $(-\infty, -1)$.

No IP

H.

81. $y = f(x) = x \ln x$ **A.** $D = (0, \infty)$ **B.** No y -intercept; x -intercept 1. **C.** No symmetry **D.** No asymptote

[Note that the graph approaches the point $(0, 0)$ as $x \rightarrow 0^+$.]

E. $f'(x) = x(1/x) + (\ln x)(1) = 1 + \ln x$, so $f'(x) \rightarrow -\infty$ as $x \rightarrow 0^+$

and $f'(x) \rightarrow \infty$ as $x \rightarrow \infty$. $f'(x) = 0 \Leftrightarrow \ln x = -1 \Leftrightarrow$

$x = e^{-1} = 1/e$. $f'(x) > 0$ for $x > 1/e$, so f is decreasing on $(0, 1/e)$

and increasing on $(1/e, \infty)$. **F.** Local minimum: $f(1/e) = -1/e$.

No local maximum. **G.** $f''(x) = 1/x$, so $f''(x) > 0$ for $x > 0$. The

graph is CU on $(0, \infty)$ and there is no IP.

H.

82. $y = f(x) = e^{2x-x^2}$ A. $D = \mathbb{R}$ B. y -intercept 1; no x -intercept C. No symmetry D. $\lim_{x \rightarrow \pm\infty} e^{2x-x^2} = 0$,

so $y = 0$ is a HA. E. $y = f(x) = e^{2x-x^2} \Rightarrow f'(x) = 2(1-x)e^{2x-x^2} > 0 \Leftrightarrow x < 1$, so f is increasing on $(-\infty, 1)$ and decreasing on $(1, \infty)$. F. $f(1) = e$ is a local and absolute maximum value.

G. $f''(x) = 2(2x^2 - 4x + 1)e^{2x-x^2} = 0 \Leftrightarrow x = 1 \pm \frac{\sqrt{2}}{2}$.

$f''(x) > 0 \Leftrightarrow x < 1 - \frac{\sqrt{2}}{2}$ or $x > 1 + \frac{\sqrt{2}}{2}$, so f is CU on $(-\infty, 1 - \frac{\sqrt{2}}{2})$ and $(1 + \frac{\sqrt{2}}{2}, \infty)$, and CD on $(1 - \frac{\sqrt{2}}{2}, 1 + \frac{\sqrt{2}}{2})$.

IP at $(1 \pm \frac{\sqrt{2}}{2}, \sqrt{e})$

83. $y = f(x) = e^x + e^{-3x}$ A. $D = \mathbb{R}$ B. y -intercept 2; no x -intercept C. No symmetry

D. $\lim_{x \rightarrow \pm\infty} (e^x + e^{-3x}) = \infty$, no asymptote E. $y = f(x) = e^x + e^{-3x} \Rightarrow$

$f'(x) = e^x - 3e^{-3x} = e^{-3x}(e^{4x} - 3) > 0 \Leftrightarrow e^{4x} > 3 \Leftrightarrow$

$4x > \ln 3 \Leftrightarrow x > \frac{1}{4} \ln 3 \approx 0.27$, so f is increasing on $(\frac{1}{4} \ln 3, \infty)$

and decreasing on $(-\infty, \frac{1}{4} \ln 3)$.

F. Absolute minimum value $f(\frac{1}{4} \ln 3) = 3^{1/4} + 3^{-3/4} \approx 1.75$.

G. $f''(x) = e^x + 9e^{-3x} > 0$, so f is CU on $(-\infty, \infty)$. No IP

84. $y = f(x) = \ln(x^2 - 1)$ A. $D = (-\infty, -1) \cup (1, \infty)$ B. No y -intercept; x -intercepts $\pm\sqrt{2}$ C. Symmetric about the y -axis D. $\lim_{x \rightarrow \pm\infty} \ln(x^2 - 1) = \infty$, $\lim_{x \rightarrow 1^+} \ln(x^2 - 1) = -\infty$, $\lim_{x \rightarrow -1^-} \ln(x^2 - 1) = -\infty$, so $x = 1$

and $x = -1$ are VA. E. $y = f(x) = \ln(x^2 - 1) \Rightarrow f'(x) = \frac{2x}{x^2 - 1} > 0$ for $x > 1$ and $f'(x) < 0$

for $x < -1$, so f is increasing on $(1, \infty)$ and decreasing on $(-\infty, -1)$.

Note that the domain of f is $|x| > 1$. F. No extreme value

G. $f''(x) = -2 \frac{x^2 + 1}{(x^2 - 1)^2} < 0$, so f is CD on $(-\infty, -1)$ and $(1, \infty)$.

No IP

85.

From the graph, we estimate the points of inflection to be about

$(\pm 0.82, 0.22)$. $f(x) = e^{-1/x^2} \Rightarrow f'(x) = 2x^{-3}e^{-1/x^2} \Rightarrow$

$$f''(x) = 2 \left[x^{-3}(2x^{-3})e^{-1/x^2} + e^{-1/x^2}(-3x^{-4}) \right]$$

$$= 2x^{-6}e^{-1/x^2}(2 - 3x^2).$$

This is 0 when $2 - 3x^2 = 0 \Leftrightarrow x = \pm\sqrt{\frac{2}{3}}$, so the inflection points are $(\pm\sqrt{\frac{2}{3}}, e^{-3/2})$.

86. We exclude the case $c = 0$, since in that case $f(x) = 0$ for all x . To find the maxima and minima, we differentiate:

$$f(x) = cxe^{-cx^2} \Rightarrow f'(x) = c[xe^{-cx^2}(-2cx) + e^{-cx^2}(1)] = ce^{-cx^2}(-2cx^2 + 1). \text{ This is 0 where}$$

$-2cx^2 + 1 = 0 \Leftrightarrow x = \pm 1/\sqrt{2c}$. So if $c > 0$, there are two maxima or minima, whose x -coordinates approach 0 as c increases. The negative root gives a minimum and the positive root gives a maximum, by the First Derivative Test. By substituting back into the equation, we see that $f(\pm 1/\sqrt{2c}) = c(\pm 1/\sqrt{2c})e^{-c(\pm 1/\sqrt{2c})^2} = \pm \sqrt{c/2e}$.

So as c increases, the extreme points become more pronounced. Note that if $c > 0$, then $\lim_{x \rightarrow \pm\infty} f(x) = 0$. If $c < 0$, then there are no extreme values, and $\lim_{x \rightarrow \pm\infty} f(x) = \mp\infty$.

To find the points of inflection, we differentiate again: $f'(x) = ce^{-cx^2}(-2cx^2 + 1) \Rightarrow f''(x) = c[e^{-cx^2}(-4cx) + (-2cx^2 + 1)(-2cxe^{-cx^2})] = -2c^2xe^{-cx^2}(3 - 2cx^2)$. This is 0 at $x = 0$ and where $3 - 2cx^2 = 0 \Leftrightarrow x = \pm\sqrt{3/(2c)} \Rightarrow$ IP at $(\pm\sqrt{3/(2c)}, \pm\sqrt{3c/2}e^{-3/2})$. If $c > 0$ there are three inflection points, and as c increases, the x -coordinates of the nonzero inflection points approach 0. If $c < 0$, there is only one inflection point, the origin.

87. $s(t) = Ae^{-ct} \cos(\omega t + \delta) \Rightarrow$

$$v(t) = s'(t) = A\{e^{-ct}[-\omega \sin(\omega t + \delta)] + \cos(\omega t + \delta)(-ce^{-ct})\} \\ = -Ae^{-ct}[\omega \sin(\omega t + \delta) + c \cos(\omega t + \delta)] \Rightarrow$$

$$a(t) = v'(t) = -A\{e^{-ct}[\omega^2 \cos(\omega t + \delta) - c\omega \sin(\omega t + \delta)] + [\omega \sin(\omega t + \delta) + c \cos(\omega t + \delta)](-ce^{-ct})\} \\ = -Ae^{-ct}[\omega^2 \cos(\omega t + \delta) - c\omega \sin(\omega t + \delta) - c\omega \sin(\omega t + \delta) - c^2 \cos(\omega t + \delta)] \\ = -Ae^{-ct}[(\omega^2 - c^2) \cos(\omega t + \delta) - 2c\omega \sin(\omega t + \delta)] \\ = Ae^{-ct}[(c^2 - \omega^2) \cos(\omega t + \delta) + 2c\omega \sin(\omega t + \delta)]$$

88. (a) Let $f(x) = \ln x + x - 3$. Then $f'(x) = 1/x + 1 > 0$ (for $x > 0$) and $f(2) \approx -0.307$ and $f(e) \approx 0.718$. f is differentiable on $(2, e)$, continuous on $[2, e]$ and $f(2) < 0$, $f(e) > 0$. Therefore, by the Intermediate Value Theorem there exists a number c in $(2, e)$ such that $f(c) = 0$. Thus, there is one root. But $f'(x) > 0$ for $x \in (2, e)$, so f is increasing on $(2, e)$, which means that there is exactly one root.

(b) We use Newton's Method with $f(x) = \ln x + x - 3$, $f'(x) = 1/x + 1$, and $x_1 = 2$.

$$x_2 = x_1 - \frac{\ln x_1 + x_1 - 3}{1/x_1 + 1} = 2 - \frac{\ln 2 + 2 - 3}{1/2 + 1} \approx 2.20457. \text{ Similarly, } x_3 \approx 2.20794, x_4 = 2.20794. \text{ Thus, the root of the equation, correct to four decimal places, is } 2.2079.$$

89. Let $P(t) = \frac{64}{1 + 31e^{-0.7944t}} = \frac{A}{1 + Be^{ct}} = A(1 + Be^{ct})^{-1}$, where $A = 64$, $B = 31$, and $c = -0.7944$.

$$P'(t) = -A(1 + Be^{ct})^{-2} (Bce^{ct}) = -ABce^{ct}(1 + Be^{ct})^{-2}$$

$$\begin{aligned} P''(t) &= -ABce^{ct} \left[-2(1 + Be^{ct})^{-3} (Bce^{ct}) \right] + (1 + Be^{ct})^{-2} (-ABc^2e^{ct}) \\ &= -ABc^2e^{ct}(1 + Be^{ct})^{-3} [-2Be^{ct} + (1 + Be^{ct})] = -\frac{ABc^2e^{ct}(1 - Be^{ct})}{(1 + Be^{ct})^3} \end{aligned}$$

The population is increasing most rapidly when its graph changes from CU to CD; that is,

when $P''(t) = 0$ in this case. $P''(t) = 0 \Rightarrow Be^{ct} = 1 \Rightarrow e^{ct} = \frac{1}{B} \Rightarrow$

$$ct = \ln \frac{1}{B} \Rightarrow t = \frac{\ln(1/B)}{c} = \frac{\ln(1/31)}{-0.7944} \approx 4.32 \text{ days. Note that}$$

$$P\left(\frac{1}{c} \ln \frac{1}{B}\right) = \frac{A}{1 + Be^{c(1/c) \ln(1/B)}} = \frac{A}{1 + Be^{\ln(1/B)}} = \frac{A}{1 + B(1/B)} = \frac{A}{1 + 1} = \frac{A}{2}, \text{ one-half the limit of } P \text{ as } t \rightarrow \infty.$$

90. Let $t = 4u$. Then $dt = 4 du$ and

$$\begin{aligned} \int_0^4 \frac{1}{16 + t^2} dt &= \int_0^1 \frac{1}{16 + 16u^2} \cdot 4 du = \frac{1}{4} \int_0^1 \frac{du}{1 + u^2} = \frac{1}{4} [\tan^{-1} u]_0^1 \\ &= \frac{1}{4} (\tan^{-1} 1 - \tan^{-1} 0) = \frac{1}{4} \left(\frac{\pi}{4} - 0 \right) = \frac{\pi}{16} \end{aligned}$$

91. Let $u = -2y^2$. Then $du = -4y dy$ and

$$\int_0^1 ye^{-2y^2} dy = \int_0^{-2} e^u \left(-\frac{1}{4} du\right) = -\frac{1}{4} [e^u]_0^{-2} = -\frac{1}{4} (e^{-2} - 1) = \frac{1}{4} (1 - e^{-2}).$$

92. $\int_2^5 \frac{dr}{1 + 2r} = \frac{1}{2} [\ln |1 + 2r|]_2^5 = \frac{1}{2} (\ln 11 - \ln 5) = \frac{1}{2} \ln \frac{11}{5}$

93. $\int_2^4 \frac{1 + x - x^2}{x^2} dx = \int_2^4 \left(x^{-2} + \frac{1}{x} - 1 \right) dx = \left[-\frac{1}{x} + \ln x - x \right]_2^4$
 $= \left(-\frac{1}{4} + \ln 4 - 4 \right) - \left(-\frac{1}{2} + \ln 2 - 2 \right) = \ln 2 - \frac{7}{4}$

94. Let $u = \sin x$. Then $du = \cos x dx$, so

$$\int_0^{\pi/2} \frac{\cos x}{1 + \sin^2 x} dx = \int_0^1 \frac{1}{1 + u^2} du = [\tan^{-1} u]_0^1 = \tan^{-1} 1 - \tan^{-1} 0 = \frac{\pi}{4} - 0 = \frac{\pi}{4}$$

95. Let $u = \sqrt{x}$. Then $du = \frac{dx}{2\sqrt{x}} \Rightarrow \int \frac{e^{\sqrt{x}}}{\sqrt{x}} dx = 2 \int e^u du = 2e^u + C = 2e^{\sqrt{x}} + C.$

96. Let $u = \ln x$. Then $du = \frac{dx}{x} \Rightarrow \int \frac{\cos(\ln x)}{x} dx = \int \cos u du = \sin u + C = \sin(\ln x) + C.$

97. Let $u = x^2 + 2x$. Then $du = (2x + 2) dx = 2(x + 1) dx$ and

$$\int \frac{x + 1}{x^2 + 2x} dx = \int \frac{\frac{1}{2} du}{u} = \frac{1}{2} \ln |u| + C = \frac{1}{2} \ln |x^2 + 2x| + C.$$

98. Let $u = e^{-x}$. Then $du = -e^{-x} dx$ and

$$\int \frac{e^{-x}}{1 + e^{-2x}} dx = \int \frac{-du}{1 + u^2} = -\tan^{-1} u + C = -\tan^{-1}(e^{-x}) + C.$$

99. Let $u = \ln(\cos x)$. Then $du = \frac{-\sin x}{\cos x} dx = -\tan x dx \Rightarrow$

$$\int \tan x \ln(\cos x) dx = -\int u du = -\frac{1}{2}u^2 + C = -\frac{1}{2}[\ln(\cos x)]^2 + C.$$

100. Let $u = x^2$. Then $du = 2x dx \Rightarrow \int \frac{x}{\sqrt{1-x^4}} dx = \frac{1}{2} \int \frac{du}{\sqrt{1-u^2}} = \frac{1}{2} \sin^{-1} u + C = \frac{1}{2} \sin^{-1}(x^2) + C.$

101. Let $u = \tan \theta$. Then $du = \sec^2 \theta d\theta$ and $\int 2^{\tan \theta} \sec^2 \theta d\theta = \int 2^u du = \frac{2^u}{\ln 2} + C = \frac{2^{\tan \theta}}{\ln 2} + C.$

102. $\int \sinh au du = \frac{1}{a} \cosh au + C$

103. Let $u = 1 + \sec \theta$, so $du = \sec \theta \tan \theta d\theta \Rightarrow \int \frac{\sec \theta \tan \theta}{1 + \sec \theta} d\theta = \int \frac{1}{u} du = \ln |u| + C = \ln |1 + \sec \theta| + C.$

104. $1 + e^{2x} > e^{2x} \Rightarrow \sqrt{1 + e^{2x}} > \sqrt{e^{2x}} = e^x \Rightarrow \int_0^1 \sqrt{1 + e^{2x}} dx \geq \int_0^1 e^x dx = e^x \Big|_0^1 = e - 1$

105. $\cos x \leq 1 \Rightarrow e^x \cos x \leq e^x \Rightarrow \int_0^1 e^x \cos x dx \leq \int_0^1 e^x dx = e^x \Big|_0^1 = e - 1$

106. For $0 \leq x \leq 1$, $0 \leq \sin^{-1} x \leq \frac{\pi}{2}$, so $\int_0^1 x \sin^{-1} x dx \leq \int_0^1 x \left(\frac{\pi}{2}\right) dx = \frac{\pi}{4} x^2 \Big|_0^1 = \frac{\pi}{4}.$

107. $f(x) = \int_1^{\sqrt{x}} \frac{e^s}{s} ds \Rightarrow f'(x) = \frac{d}{dx} \int_1^{\sqrt{x}} \frac{e^s}{s} ds = \frac{e^{\sqrt{x}}}{\sqrt{x}} \frac{d}{dx} \sqrt{x} = \frac{e^{\sqrt{x}}}{\sqrt{x}} \frac{1}{2\sqrt{x}} = \frac{e^{\sqrt{x}}}{2x}$

108. $f(x) = \int_{\ln x}^{2x} e^{-t^2} dt \Rightarrow f'(x) = \frac{d}{dx} \int_{\ln x}^{2x} e^{-t^2} dt = -\frac{d}{dx} \int_0^{\ln x} e^{-t^2} dt + \frac{d}{dx} \int_0^{2x} e^{-t^2} dt$
 $= -e^{-(\ln x)^2} \left(\frac{1}{x}\right) + e^{-(2x)^2} (2) = -\frac{e^{-(\ln x)^2}}{x} + 2e^{-4x^2}$

109. $f_{\text{ave}} = \frac{1}{4-1} \int_1^4 \frac{1}{x} dx = \frac{1}{3} [\ln |x|]_1^4 = \frac{1}{3} [\ln 4 - \ln 1] = \frac{1}{3} \ln 4$

110. $A = \int_{-2}^0 (e^{-x} - e^x) dx + \int_0^1 (e^x - e^{-x}) dx = [-e^{-x} - e^x]_{-2}^0 + [e^x + e^{-x}]_0^1$
 $= [(-1 - 1) - (-e^2 - e^{-2})] + [(e + e^{-1}) - (1 + 1)] = e^2 + e + e^{-1} + e^{-2} - 4$

111. $V = \int_0^1 \frac{2\pi x}{1+x^4} dx$ by cylindrical shells. Let $u = x^2 \Rightarrow du = 2x dx$. Then

$$V = \int_0^1 \frac{\pi}{1+u^2} du = \pi [\tan^{-1} u]_0^1 = \pi (\tan^{-1} 1 - \tan^{-1} 0) = \pi \left(\frac{\pi}{4}\right) = \frac{\pi^2}{4}.$$

112. $f(x) = x + x^2 + e^x \Rightarrow f'(x) = 1 + 2x + e^x$ and $f(0) = 1 \Rightarrow g(1) = 0$, so

$$g'(1) = \frac{1}{f'(g(1))} = \frac{1}{f'(0)} = \frac{1}{2}.$$

113. $f(x) = \ln x + \tan^{-1} x \Rightarrow f(1) = \ln 1 + \tan^{-1} 1 = \frac{\pi}{4} \Rightarrow g\left(\frac{\pi}{4}\right) = 1.$

$$f'(x) = \frac{1}{x} + \frac{1}{1+x^2}, \text{ so } g'\left(\frac{\pi}{4}\right) = \frac{1}{f'(1)} = \frac{1}{3/2} = \frac{2}{3}.$$

114.

The area of such a rectangle is just the product of its sides, that is,

$A(x) = x \cdot e^{-x}$. We want to find the maximum of this function, so we differentiate: $A'(x) = x(-e^{-x}) + e^{-x}(1) = e^{-x}(1 - x)$. This is 0 only at $x = 1$, and changes from positive to negative there, so by the First Derivative Test this gives a local maximum. So the largest area is $A(1) = 1/e$.

115.

We find the equation of a tangent to the curve $y = e^{-x}$, so that we can find the x - and y -intercepts of this tangent, and then we can find the area of the triangle. The slope of the tangent at the point (a, e^{-a}) is given by $\left. \frac{d}{dx} e^{-x} \right|_{x=a} = -e^{-a}$, and so the equation of the tangent is $y - e^{-a} = -e^{-a}(x - a) \Leftrightarrow y = e^{-a}(a - x + 1)$.

The y -intercept of this line is $y = e^{-a}(a - 0 + 1) = e^{-a}(a + 1)$. To find the x -intercept we set

$y = 0 \Rightarrow e^{-a}(a - x + 1) = 0 \Rightarrow x = a + 1$. So the area of the triangle is

$A(a) = \frac{1}{2} [e^{-a}(a + 1)](a + 1) = \frac{1}{2} e^{-a}(a + 1)^2$. We differentiate this with respect to a :

$A'(a) = \frac{1}{2} [e^{-a}(2)(a + 1) + (a + 1)^2 e^{-a}(-1)] = \frac{1}{2} e^{-a}(1 - a^2)$. This is 0 at $a = \pm 1$, and the root $a = 1$ gives a maximum, by the First Derivative Test. So the maximum area of the triangle is

$$A(1) = \frac{1}{2} e^{-1}(1 + 1)^2 = 2e^{-1} = 2/e.$$

116. Using Formula 5.2.3 with $a = 0$ and $b = 1$, we have $\int_0^1 e^x dx = \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n e^{i/n}$. This series is a geometric

series with $a = r = e^{1/n}$, so $\sum_{i=1}^n e^{i/n} = e^{1/n} \frac{e^{n/n} - 1}{e^{1/n} - 1} = e^{1/n} \frac{e - 1}{e^{1/n} - 1} \Rightarrow$

$$\int_0^1 e^x dx = \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n e^{i/n} = \lim_{n \rightarrow \infty} (e - 1) e^{1/n} \frac{1/n}{e^{1/n} - 1}. \text{ As } n \rightarrow \infty, 1/n \rightarrow 0^+, \text{ so } e^{1/n} \rightarrow e^0 = 1.$$

Let $t = 1/n$. Then $e^{1/n} - 1 = e^t - 1 \rightarrow 0^+$, so l'Hospital's Rule gives $\lim_{t \rightarrow 0} \frac{t}{e^t - 1} = \lim_{t \rightarrow 0} \frac{1}{e^t} = 1$ and we have

$$\int_0^1 e^x dx = \left[\lim_{t \rightarrow 0^+} (e - 1) e^t \right] \left[\lim_{t \rightarrow 0^+} \frac{t}{e^t - 1} \right] = e - 1.$$

117. $\lim_{x \rightarrow -1} F(x) = \lim_{x \rightarrow -1} \frac{b^{x+1} - a^{x+1}}{x + 1} \stackrel{H}{=} \lim_{x \rightarrow -1} \frac{b^{x+1} \ln b - a^{x+1} \ln a}{1} = \ln b - \ln a = F(-1)$, so F is continuous at -1 .

118. Let $\theta_1 = \operatorname{arccot} x$, so $\cot \theta_1 = x = x/1$. So $\sin(\operatorname{arccot} x) = \sin \theta_1 = \frac{1}{\sqrt{x^2 + 1}}$.

Let $\theta_2 = \arctan \left[\frac{1}{\sqrt{x^2 + 1}} \right]$, so $\tan \theta_2 = \frac{1}{\sqrt{x^2 + 1}}$.

Hence, $\cos(\arctan(\sin(\operatorname{arccot} x))) = \cos \theta_2 = \frac{\sqrt{x^2 + 1}}{\sqrt{x^2 + 2}} = \sqrt{\frac{x^2 + 1}{x^2 + 2}}$.

119. Differentiating both sides of the given equation, using the Fundamental Theorem for each side, gives

$$f(x) = e^{2x} + 2xe^{2x} + e^{-x}f(x). \text{ So } f(x)(1 - e^{-x}) = e^{2x} + 2xe^{2x}. \text{ Hence } f(x) = \frac{e^{2x}(1 + 2x)}{1 - e^{-x}}.$$

120. (a) Let $f(x) = x - \ln x - 1$, so $f'(x) = 1 - \frac{1}{x} = \frac{x-1}{x}$. Since $x > 0$, $f'(x) < 0$ for $0 < x < 1$ and $f'(x) > 0$ for $x > 1$. So there is an absolute minimum at $x = 1$ with $f(1) = 0$.

So for $x > 0$, $x \neq 1$, $x - \ln x - 1 = f(x) > f(1) = 0$, and hence $\ln x < x - 1$.

(b) Here let $f(x) = \ln x - \frac{x-1}{x} = \ln x - 1 + \frac{1}{x}$. So $f'(x) = \frac{1}{x} - \frac{1}{x^2} = \frac{x-1}{x^2}$. As in (a), we see that there is an absolute minimum value at $x = 1$ and that $f(1) = 0$. So for $x > 0$, $x \neq 1$, $\ln x - \frac{x-1}{x} = f(x) > f(1) = 0$ and hence $\frac{x-1}{x} < \ln x$.

(c) Let $b > a > 0$, so $b/a > 1$. Letting $x = b/a$ in the inequalities in (a) and (b) gives

$\frac{b-a}{b} = \frac{b/a - 1}{b/a} < \ln \frac{b}{a} < \frac{b}{a} - 1 = \frac{b-a}{a}$. Noting that $\ln \frac{b}{a} = \ln b - \ln a$, the result follows after dividing through by $b - a$.

(d) Let $f(x) = \ln x$. From the given diagram, we see that

(slope of tangent at $x = b$) < (slope of secant line) < (slope of tangent at $x = a$). Since $f'(x) = \frac{1}{x}$, we

therefore have $\frac{1}{b} < \frac{\ln b - \ln a}{b - a} < \frac{1}{a}$. To make this geometric argument more rigorous, we could use the Mean Value Theorem: For any a and b with $0 < a < b$, there exists some $c \in (a, b)$ for which

$$f'(c) = \frac{1}{c} = \frac{\ln b - \ln a}{b - a}. \text{ But } \frac{1}{x} \text{ is a decreasing function on } (0, \infty), \text{ so } \frac{1}{b} < \frac{1}{c} = \frac{\ln b - \ln a}{b - a} < \frac{1}{a}.$$

(e) Since $\frac{1}{b} < \frac{1}{x} < \frac{1}{a}$ for $a < x < b$, Property 8 says that $\frac{1}{b}(b-a) < \int_a^b \frac{1}{x} dx < \frac{1}{a}(b-a) \Rightarrow$

$\frac{1}{b}(b-a) < \ln b - \ln a < \frac{1}{a}(b-a) \Rightarrow \frac{1}{b} < \frac{\ln b - \ln a}{b - a} < \frac{1}{a}$. (Note from the proof of Property 8 that we are justified in making all of the inequalities strict.)

□ PROBLEMS PLUS

- Let $y = f(x) = e^{-x^2}$. The area of the rectangle under the curve from $-x$ to x is $A(x) = 2xe^{-x^2}$ where $x \geq 0$. We maximize $A(x)$: $A'(x) = 2e^{-x^2} - 4x^2e^{-x^2} = 2e^{-x^2}(1 - 2x^2) = 0 \Rightarrow x = \frac{1}{\sqrt{2}}$. This gives a maximum since $A'(x) > 0$ for $0 \leq x < \frac{1}{\sqrt{2}}$ and $A'(x) < 0$ for $x > \frac{1}{\sqrt{2}}$. We next determine the points of inflection of $f(x)$. Notice that $f'(x) = -2xe^{-x^2} = -A(x)$. So $f''(x) = -A'(x)$ and hence, $f''(x) < 0$ for $-\frac{1}{\sqrt{2}} < x < \frac{1}{\sqrt{2}}$ and $f''(x) > 0$ for $x < -\frac{1}{\sqrt{2}}$ and $x > \frac{1}{\sqrt{2}}$. So $f(x)$ changes concavity at $x = \pm \frac{1}{\sqrt{2}}$, and the two vertices of the rectangle of largest area are at the inflection points.
- We use proof by contradiction. Suppose that $\log_2 5$ is a rational number. Then $\log_2 5 = m/n$ where m and n are positive integers $\Rightarrow 2^{m/n} = 5 \Rightarrow 2^m = 5^n$. But this is impossible since 2^m is even and 5^n is odd. So $\log_2 5$ is irrational.

- Consider the statement that $\frac{d^n}{dx^n}(e^{ax} \sin bx) = r^n e^{ax} \sin(bx + n\theta)$. For $n = 1$,

$$\frac{d}{dx}(e^{ax} \sin bx) = ae^{ax} \sin bx + be^{ax} \cos bx, \text{ and}$$

$$\begin{aligned} re^{ax} \sin(bx + \theta) &= re^{ax} [\sin bx \cos \theta + \cos bx \sin \theta] = re^{ax} \left(\frac{a}{r} \sin bx + \frac{b}{r} \cos bx \right) \\ &= ae^{ax} \sin bx + be^{ax} \cos bx \end{aligned}$$

$$\text{since } \tan \theta = \frac{b}{a} \Rightarrow \sin \theta = \frac{b}{r} \text{ and } \cos \theta = \frac{a}{r}.$$

So the statement is true for $n = 1$. Assume it is true for $n = k$. Then

$$\begin{aligned} \frac{d^{k+1}}{dx^{k+1}}(e^{ax} \sin bx) &= \frac{d}{dx} \left[r^k e^{ax} \sin(bx + k\theta) \right] = r^k ae^{ax} \sin(bx + k\theta) + r^k e^{ax} b \cos(bx + k\theta) \\ &= r^k e^{ax} [a \sin(bx + k\theta) + b \cos(bx + k\theta)] \end{aligned}$$

But

$$\begin{aligned} \sin[bx + (k+1)\theta] &= \sin[(bx + k\theta) + \theta] = \sin(bx + k\theta) \cos \theta + \sin \theta \cos(bx + k\theta) \\ &= \frac{a}{r} \sin(bx + k\theta) + \frac{b}{r} \cos(bx + k\theta) \end{aligned}$$

Hence, $a \sin(bx + k\theta) + b \cos(bx + k\theta) = r \sin[bx + (k+1)\theta]$. So

$$\begin{aligned} \frac{d^{k+1}}{dx^{k+1}}(e^{ax} \sin bx) &= r^k e^{ax} [a \sin(bx + k\theta) + b \cos(bx + k\theta)] = r^k e^{ax} [r \sin(bx + (k+1)\theta)] \\ &= r^{k+1} e^{ax} \sin(bx + (k+1)\theta) \end{aligned}$$

Therefore, the statement is true for all n by mathematical induction.

4. Let $y = \tan^{-1} x$. Then $\tan y = x$, so from the triangle we see that

$$\sin(\tan^{-1} x) = \sin y = \frac{x}{\sqrt{1+x^2}}. \text{ Using this fact we have that}$$

$$\sin(\tan^{-1}(\sinh x)) = \frac{\sinh x}{\sqrt{1+\sinh^2 x}} = \frac{\sinh x}{\cosh x} = \tanh x. \text{ Hence,}$$

$$\sin^{-1}(\tanh x) = \sin^{-1}(\sin(\tan^{-1}(\sinh x))) = \tan^{-1}(\sinh x).$$

5. We first show that $\frac{x}{1+x^2} < \tan^{-1} x$ for $x > 0$. Let $f(x) = \tan^{-1} x - \frac{x}{1+x^2}$. Then

$$f'(x) = \frac{1}{1+x^2} - \frac{1(1+x^2) - x(2x)}{(1+x^2)^2} = \frac{(1+x^2) - (1-x^2)}{(1+x^2)^2} = \frac{2x^2}{(1+x^2)^2} > 0 \text{ for } x > 0. \text{ So } f(x) \text{ is}$$

increasing on $(0, \infty)$. Hence, $0 < x \Rightarrow 0 = f(0) < f(x) = \tan^{-1} x - \frac{x}{1+x^2}$. So $\frac{x}{1+x^2} < \tan^{-1} x$

for $0 < x$. We next show that $\tan^{-1} x < x$ for $x > 0$. Let $h(x) = x - \tan^{-1} x$. Then

$$h'(x) = 1 - \frac{1}{1+x^2} = \frac{x^2}{1+x^2} > 0. \text{ Hence, } h(x) \text{ is increasing on } (0, \infty). \text{ So for } 0 < x,$$

$0 = h(0) < h(x) = x - \tan^{-1} x$. Hence, $\tan^{-1} x < x$ for $x > 0$, and we conclude that $\frac{x}{1+x^2} < \tan^{-1} x < x$ for $x > 0$.

6. The shaded region has area $\int_0^1 f(x) dx = \frac{1}{3}$. The integral $\int_0^1 f^{-1}(y) dy$

gives the area of the unshaded region, which we know to be $1 - \frac{1}{3} = \frac{2}{3}$.

$$\text{So } \int_0^1 f^{-1}(y) dy = \frac{2}{3}.$$

7. By the Fundamental Theorem of Calculus, $f(x) = \int_1^x \sqrt{1+t^3} dt \Rightarrow f'(x) = \sqrt{1+x^3} > 0$ for $x > -1$.

So f is increasing on $(-1, \infty)$ and hence is one-to-one. Note that $f(1) = 0$, so $f^{-1}(1) = 0 \Rightarrow$

$$(f^{-1})'(0) = 1/f'(1) = \frac{1}{\sqrt{2}}.$$

8. $y = \frac{x}{\sqrt{a^2-1}} - \frac{2}{\sqrt{a^2-1}} \arctan \frac{\sin x}{a + \sqrt{a^2-1} + \cos x}$. Let $k = a + \sqrt{a^2-1}$. Then

$$\begin{aligned} y' &= \frac{1}{\sqrt{a^2-1}} - \frac{2}{\sqrt{a^2-1}} \cdot \frac{1}{1 + \sin^2 x / (k + \cos x)^2} \cdot \frac{\cos x(k + \cos x) + \sin^2 x}{(k + \cos x)^2} \\ &= \frac{1}{\sqrt{a^2-1}} - \frac{2}{\sqrt{a^2-1}} \cdot \frac{k \cos x + \cos^2 x + \sin^2 x}{(k + \cos x)^2 + \sin^2 x} = \frac{1}{\sqrt{a^2-1}} - \frac{2}{\sqrt{a^2-1}} \cdot \frac{k \cos x + 1}{k^2 + 2k \cos x + 1} \\ &= \frac{k^2 + 2k \cos x + 1 - 2k \cos x - 2}{\sqrt{a^2-1}(k^2 + 2k \cos x + 1)} = \frac{k^2 - 1}{\sqrt{a^2-1}(k^2 + 2k \cos x + 1)} \end{aligned}$$

But $k^2 = 2a^2 + 2a\sqrt{a^2-1} - 1 = 2a(a + \sqrt{a^2-1}) - 1 = 2ak - 1$, so $k^2 + 1 = 2ak$, and

$$k^2 - 1 = 2(ak - 1). \text{ So } y' = \frac{2(ak - 1)}{\sqrt{a^2 - 1}(2ak + 2k \cos x)} = \frac{ak - 1}{\sqrt{a^2 - 1}k(a + \cos x)}. \text{ But}$$

$$ak - 1 = a^2 + a\sqrt{a^2 - 1} - 1 = k\sqrt{a^2 - 1}, \text{ so } y' = 1/(a + \cos x).$$

9. If $L = \lim_{x \rightarrow \infty} \left(\frac{x+a}{x-a} \right)^x$, then L has the indeterminate form 1^∞ , so

$$\begin{aligned} \ln L &= \lim_{x \rightarrow \infty} \ln \left(\frac{x+a}{x-a} \right)^x = \lim_{x \rightarrow \infty} x \ln \left(\frac{x+a}{x-a} \right) = \lim_{x \rightarrow \infty} \frac{\ln(x+a) - \ln(x-a)}{1/x} \\ &\stackrel{H}{=} \lim_{x \rightarrow \infty} \frac{\frac{1}{x+a} - \frac{1}{x-a}}{-1/x^2} = \lim_{x \rightarrow \infty} \left[\frac{(x-a) - (x+a)}{(x+a)(x-a)} \cdot \frac{-x^2}{1} \right] \\ &= \lim_{x \rightarrow \infty} \frac{2ax^2}{x^2 - a^2} = \lim_{x \rightarrow \infty} \frac{2a}{1 - a^2/x^2} = 2a. \end{aligned}$$

Hence, $\ln L = 2a$, so $L = e^{2a}$. From the original equation, we want $L = e^1 \Rightarrow 2a = 1 \Rightarrow a = \frac{1}{2}$.

10. Case (i) (first graph): For $x + y \geq 0$, that is, $y \geq -x$, $|x + y| = x + y \leq e^x \Rightarrow y \leq e^x - x$.

Note that $y = e^x - x$ is always above the line $y = -x$ and that $y = -x$ is a slant asymptote.

Case (ii) (second graph): For $x + y < 0$, that is, $y < -x$, $|x + y| = -x - y \leq e^x \Rightarrow y \geq -x - e^x$.

Note that $-x - e^x$ is always below the line $y = -x$ and $y = -x$ is a slant asymptote.

Putting the two pieces together gives the third graph.

11. Both sides of the inequality are positive, so $\cosh(\sinh x) < \sinh(\cosh x) \Leftrightarrow \cosh^2(\sinh x) < \sinh^2(\cosh x)$
- $$\Leftrightarrow \sinh^2(\sinh x) + 1 < \sinh^2(\cosh x) \Leftrightarrow 1 < [\sinh(\cosh x) - \sinh(\sinh x)][\sinh(\cosh x) + \sinh(\sinh x)]$$
- $$\Leftrightarrow 1 < \left[\sinh\left(\frac{e^x + e^{-x}}{2}\right) - \sinh\left(\frac{e^x - e^{-x}}{2}\right) \right] \left[\sinh\left(\frac{e^x + e^{-x}}{2}\right) + \sinh\left(\frac{e^x - e^{-x}}{2}\right) \right]$$
- $$\Leftrightarrow 1 < [2 \cosh(e^x/2) \sinh(e^x/2)][2 \sinh(e^x/2) \cosh(e^x/2)] \quad [\text{use the addition formulas and cancel}]$$
- $$\Leftrightarrow 1 < [2 \sinh(e^x/2) \cosh(e^x/2)][2 \sinh(e^x/2) \cosh(e^x/2)] \Leftrightarrow 1 < \sinh e^x \sinh e^{-x},$$

by the half-angle formula. Now both e^x and e^{-x} are positive, and $\sinh y > y$ for $y > 0$, since $\sinh 0 = 0$ and

$(\sinh y - y)' = \cosh y - 1 > 0$ for $x > 0$, so $1 = e^x e^{-x} < \sinh e^x \sinh e^{-x}$. So, following this chain of

reasoning backward, we arrive at the desired result.

12. First, we recognize some symmetry in the inequality: $\frac{e^{x+y}}{xy} \geq e^2 \Leftrightarrow \frac{e^x}{x} \cdot \frac{e^y}{y} \geq e \cdot e$. This suggests that we need to show that $\frac{e^x}{x} \geq e$ for $x > 0$. If we can do this, then the inequality $\frac{e^y}{y} \geq e$ is true, and the given inequality follows. $f(x) = \frac{e^x}{x} \Rightarrow f'(x) = \frac{xe^x - e^x}{x^2} = \frac{e^x(x-1)}{x^2} = 0 \Rightarrow x = 1$. By the First Derivative Test, we have a minimum of $f(1) = e$, so $e^x/x \geq e$ for all x .

Let $f(x) = e^{2x}$ and $g(x) = k\sqrt{x}$ ($k > 0$). From the graphs of f and g , we see that f will intersect g exactly once when f and g share a tangent line. Thus, we must have $f = g$ and $f' = g'$ at $x = a$. $f(a) = g(a) \Rightarrow e^{2a} = k\sqrt{a}$ (1) and $f'(a) = g'(a) \Rightarrow 2e^{2a} = \frac{k}{2\sqrt{a}} \Rightarrow e^{2a} = \frac{k}{4\sqrt{a}}$. So we must have $k\sqrt{a} = \frac{k}{4\sqrt{a}} \Rightarrow (\sqrt{a})^2 = \frac{k}{4k} \Rightarrow a = \frac{1}{4}$. From (1), $e^{2(1/4)} = k\sqrt{1/4} \Rightarrow k = 2e^{1/2} = 2\sqrt{e} \approx 3.297$.

We see that at $x = 0$, $f(x) = a^x = 1 + x = 1$, so if $y = a^x$ is to lie above $y = 1 + x$, the two curves must just touch at $(0, 1)$, that is, we must have $f'(0) = 1$.

[To see this analytically, note that $a^x \geq 1 + x \Rightarrow a^x - 1 \geq x \Rightarrow \frac{a^x - 1}{x} \geq 1$ for $x > 0$, so $f'(0) = \lim_{x \rightarrow 0^+} \frac{a^x - 1}{x} \geq 1$. Similarly, for $x < 0$, $a^x - 1 \geq x \Rightarrow \frac{a^x - 1}{x} \leq 1$, so $f'(0) = \lim_{x \rightarrow 0^-} \frac{a^x - 1}{x} \leq 1$. Since $1 \leq f'(0) \leq 1$, we must have $f'(0) = 1$.] But $f'(x) = a^x \ln a \Rightarrow f'(0) = \ln a$, so we have $\ln a = 1 \Leftrightarrow a = e$.

Another method: The inequality certainly holds for $x \leq -1$, so consider $x > -1$, $x \neq 0$. Then $a^x \geq 1 + x \Rightarrow a \geq (1+x)^{1/x}$ for $x > 0 \Rightarrow a \geq \lim_{x \rightarrow 0^+} (1+x)^{1/x} = e$, by Equation 7.4.8. Also, $a^x \geq 1 + x \Rightarrow a \leq (1+x)^{1/x}$ for $x < 0 \Rightarrow a \leq \lim_{x \rightarrow 0^-} (1+x)^{1/x} = e$. So since $e \leq a \leq e$, we must have $a = e$.

15. Suppose that the curve $y = a^x$ intersects the line $y = x$. Then $a^{x_0} = x_0$ for some $x_0 > 0$, and hence $a = x_0^{1/x_0}$. We find the maximum value of $g(x) = x^{1/x}$, $x > 0$, because if a is larger than the maximum value of this function, then the curve $y = a^x$ does not intersect the line $y = x$. $g'(x) = e^{(1/x) \ln x} \left(-\frac{1}{x^2} \ln x + \frac{1}{x} \cdot \frac{1}{x} \right) = x^{1/x} \left(\frac{1}{x^2} \right) (1 - \ln x)$. This is 0 only where $x = e$, and for $0 < x < e$, $f'(x) > 0$, while for $x > e$, $f'(x) < 0$, so g has an absolute maximum of $g(e) = e^{1/e}$. So if $y = a^x$ intersects $y = x$, we must have $0 < a \leq e^{1/e}$. Conversely, suppose that $0 < a \leq e^{1/e}$. Then $a^e \leq e$, so the graph of $y = a^x$ lies below or touches the graph of $y = x$ at $x = e$. Also $a^0 = 1 > 0$, so the graph of $y = a^x$ lies above that of $y = x$ at $x = 0$. Therefore, by the Intermediate Value Theorem, the graphs of $y = a^x$ and $y = x$ must intersect somewhere between $x = 0$ and $x = e$.

8 TECHNIQUES OF INTEGRATION

8.1 Integration by Parts

1. Let $u = \ln x$, $dv = x dx \Rightarrow du = dx/x$, $v = \frac{1}{2}x^2$. Then by Equation 2, $\int u dv = uv - \int v du$,

$$\begin{aligned}\int x \ln x dx &= \frac{1}{2}x^2 \ln x - \int \frac{1}{2}x^2(dx/x) = \frac{1}{2}x^2 \ln x - \frac{1}{2} \int x dx = \frac{1}{2}x^2 \ln x - \frac{1}{2} \cdot \frac{1}{2}x^2 + C \\ &= \frac{1}{2}x^2 \ln x - \frac{1}{4}x^2 + C\end{aligned}$$

2. Let $u = \theta$, $dv = \sec^2 \theta d\theta \Rightarrow du = d\theta$, $v = \tan \theta$. Then

$$\int \theta \sec^2 \theta d\theta = \theta \tan \theta - \int \tan \theta d\theta = \theta \tan \theta - \ln |\sec \theta| + C.$$

3. Let $u = x$, $dv = \cos 5x dx \Rightarrow du = dx$, $v = \frac{1}{5} \sin 5x$. Then by Equation 2,

$$\int x \cos 5x dx = \frac{1}{5}x \sin 5x - \int \frac{1}{5} \sin 5x dx = \frac{1}{5}x \sin 5x + \frac{1}{25} \cos 5x + C.$$

4. Let $u = x$, $dv = e^{-x} dx \Rightarrow du = dx$, $v = -e^{-x}$. Then

$$\int x e^{-x} dx = -x e^{-x} + \int e^{-x} dx = -x e^{-x} - e^{-x} + C.$$

5. Let $u = r$, $dv = e^{r/2} dr \Rightarrow du = dr$, $v = 2e^{r/2}$. Then

$$\int r e^{r/2} dr = 2r e^{r/2} - \int 2e^{r/2} dr = 2r e^{r/2} - 4e^{r/2} + C.$$

6. Let $u = t$, $dv = \sin 2t dt \Rightarrow du = dt$, $v = -\frac{1}{2} \cos 2t$. Then

$$\int t \sin 2t dt = -\frac{1}{2}t \cos 2t + \frac{1}{2} \int \cos 2t dt = -\frac{1}{2}t \cos 2t + \frac{1}{4} \sin 2t + C.$$

7. Let $u = x^2$, $dv = \sin \pi x dx \Rightarrow du = 2x dx$ and $v = -\frac{1}{\pi} \cos \pi x$. Then

$$I = \int x^2 \sin \pi x dx = -\frac{1}{\pi} x^2 \cos \pi x + \frac{2}{\pi} \int x \cos \pi x dx (*).$$

Next let $U = x$, $dV = \cos \pi x dx \Rightarrow dU = dx$, $V = \frac{1}{\pi} \sin \pi x$, so

$$\int x \cos \pi x dx = \frac{1}{\pi} x \sin \pi x - \frac{1}{\pi} \int \sin \pi x dx = \frac{1}{\pi} x \sin \pi x + \frac{1}{\pi^2} \cos \pi x + C_1. \text{ Substituting for } \int x \cos \pi x dx \text{ in } (*),$$

$$\text{we get } I = -\frac{1}{\pi} x^2 \cos \pi x + \frac{2}{\pi} \left(\frac{1}{\pi} x \sin \pi x + \frac{1}{\pi^2} \cos \pi x + C_1 \right) = -\frac{1}{\pi} x^2 \cos \pi x + \frac{2}{\pi^2} x \sin \pi x + \frac{2}{\pi^3} \cos \pi x + C,$$

$$\text{where } C = \frac{2}{\pi} C_1.$$

8. Let $u = x^2$, $dv = \cos mx dx \Rightarrow du = 2x dx$, $v = \frac{1}{m} \sin mx$.

$$\text{Then } I = \int x^2 \cos mx dx = \frac{1}{m} x^2 \sin mx - \frac{2}{m} \int x \sin mx dx (*). \text{ Next let}$$

$$U = x, dV = \sin mx dx \Rightarrow dU = dx, V = -\frac{1}{m} \cos mx, \text{ so}$$

$$\int x \sin mx dx = -\frac{1}{m} x \cos mx + \frac{1}{m} \int \cos mx dx = -\frac{1}{m} x \cos mx + \frac{1}{m^2} \sin mx + C_1.$$

Substituting for $\int x \sin mx dx$ in (*), we get

$$I = \frac{1}{m} x^2 \sin mx - \frac{2}{m} \left(-\frac{1}{m} x \cos mx + \frac{1}{m^2} \sin mx + C_1 \right) = \frac{1}{m} x^2 \sin mx + \frac{2}{m^2} x \cos mx - \frac{2}{m^3} \sin mx + C,$$

$$\text{where } C = -\frac{2}{m} C_1.$$

9. Let $u = \ln(2x + 1)$, $dv = dx \Rightarrow du = \frac{2}{2x+1} dx$, $v = x$. Then

$$\begin{aligned}\int \ln(2x+1) dx &= x \ln(2x+1) - \int \frac{2x}{2x+1} dx = x \ln(2x+1) - \int \frac{(2x+1)-1}{2x+1} dx \\ &= x \ln(2x+1) - \int \left(1 - \frac{1}{2x+1}\right) dx = x \ln(2x+1) - x + \frac{1}{2} \ln(2x+1) + C \\ &= \frac{1}{2}(2x+1) \ln(2x+1) - x + C\end{aligned}$$

10. Let $u = \sin^{-1} x$, $dv = dx \Rightarrow du = \frac{dx}{\sqrt{1-x^2}}$, $v = x$. Then

$$\begin{aligned}\int \sin^{-1} x dx &= x \sin^{-1} x - \int \frac{x}{\sqrt{1-x^2}} dx. \text{ Setting } t = 1-x^2, \text{ we get } dt = -2x dx, \text{ so} \\ -\int \frac{x dx}{\sqrt{1-x^2}} &= -\int t^{-1/2} \left(-\frac{1}{2} dt\right) = \frac{1}{2} \left(2t^{1/2}\right) + C = t^{1/2} + C = \sqrt{1-x^2} + C. \text{ Hence,} \\ \int \sin^{-1} x dx &= x \sin^{-1} x + \sqrt{1-x^2} + C.\end{aligned}$$

11. Let $u = \arctan 4t$, $dv = dt \Rightarrow du = \frac{4}{1+(4t)^2} dt = \frac{4}{1+16t^2} dt$, $v = t$. Then

$$\begin{aligned}\int \arctan 4t dt &= t \arctan 4t - \int \frac{4t}{1+16t^2} dt = t \arctan 4t - \frac{1}{8} \int \frac{32t}{1+16t^2} dt \\ &= t \arctan 4t - \frac{1}{8} \ln(1+16t^2) + C\end{aligned}$$

12. Let $u = \ln p$, $dv = p^5 dp \Rightarrow du = \frac{1}{p} dp$, $v = \frac{1}{6} p^6$. Then

$$\int p^5 \ln p dp = \frac{1}{6} p^6 \ln p - \frac{1}{6} \int p^5 dp = \frac{1}{6} p^6 \ln p - \frac{1}{36} p^6 + C.$$

13. First let $u = (\ln x)^2$, $dv = dx \Rightarrow du = 2 \ln x \cdot \frac{1}{x} dx$, $v = x$. Then by Equation 2,

$$\begin{aligned}I = \int (\ln x)^2 dx &= x(\ln x)^2 - 2 \int x \ln x \cdot \frac{1}{x} dx = x(\ln x)^2 - 2 \int \ln x dx. \text{ Next let } U = \ln x, dV = dx \Rightarrow \\ dU &= 1/x dx, V = x \text{ to get } \int \ln x dx = x \ln x - \int x \cdot (1/x) dx = x \ln x - \int dx = x \ln x - x + C_1. \text{ Thus,} \\ I &= x(\ln x)^2 - 2(x \ln x - x + C_1) = x(\ln x)^2 - 2x \ln x + 2x + C, \text{ where } C = -2C_1.\end{aligned}$$

14. Let $u = t^3$, $dv = e^t dt \Rightarrow du = 3t^2 dt$, $v = e^t$. Then $I = \int t^3 e^t dt = t^3 e^t - \int 3t^2 e^t dt$. Integrate by parts twice more with $dv = e^t dt$.

$$\begin{aligned}I &= t^3 e^t - (3t^2 e^t - \int 6te^t dt) = t^3 e^t - 3t^2 e^t + 6te^t - \int 6e^t dt \\ &= t^3 e^t - 3t^2 e^t + 6te^t - 6e^t + C = (t^3 - 3t^2 + 6t - 6)e^t + C\end{aligned}$$

More generally, if $p(t)$ is a polynomial of degree n in t , then repeated integration by parts shows that

$$\int p(t) e^t dt = \left[p(t) - p'(t) + p''(t) - p'''(t) + \cdots + (-1)^n p^{(n)}(t) \right] e^t + C.$$

15. First let $u = \sin 3\theta$, $dv = e^{2\theta} d\theta \Rightarrow du = 3 \cos 3\theta d\theta$, $v = \frac{1}{2}e^{2\theta}$. Then

$$I = \int e^{2\theta} \sin 3\theta d\theta = \frac{1}{2}e^{2\theta} \sin 3\theta - \frac{3}{2} \int e^{2\theta} \cos 3\theta d\theta. \text{ Next let } U = \cos 3\theta,$$

$$dV = e^{2\theta} d\theta \Rightarrow dU = -3 \sin 3\theta d\theta, V = \frac{1}{2}e^{2\theta} \text{ to get}$$

$$\int e^{2\theta} \cos 3\theta d\theta = \frac{1}{2}e^{2\theta} \cos 3\theta + \frac{3}{2} \int e^{2\theta} \sin 3\theta d\theta. \text{ Substituting in the previous formula gives}$$

$$I = \frac{1}{2}e^{2\theta} \sin 3\theta - \frac{3}{4}e^{2\theta} \cos 3\theta - \frac{9}{4} \int e^{2\theta} \sin 3\theta d\theta = \frac{1}{2}e^{2\theta} \sin 3\theta - \frac{3}{4}e^{2\theta} \cos 3\theta - \frac{9}{4}I \Rightarrow$$

$$\frac{13}{4}I = \frac{1}{2}e^{2\theta} \sin 3\theta - \frac{3}{4}e^{2\theta} \cos 3\theta + C_1. \text{ Hence, } I = \frac{1}{13}e^{2\theta}(2 \sin 3\theta - 3 \cos 3\theta) + C, \text{ where } C = \frac{4}{13}C_1.$$

16. First let $u = e^{-\theta}$, $dv = \cos 2\theta d\theta \Rightarrow du = -e^{-\theta} d\theta$, $v = \frac{1}{2} \sin 2\theta$. Then

$$I = \int e^{-\theta} \cos 2\theta d\theta = \frac{1}{2}e^{-\theta} \sin 2\theta - \int \frac{1}{2} \sin 2\theta (-e^{-\theta} d\theta) = \frac{1}{2}e^{-\theta} \sin 2\theta + \frac{1}{2} \int e^{-\theta} \sin 2\theta d\theta.$$

$$\text{Next let } U = e^{-\theta}, dV = \sin 2\theta d\theta \Rightarrow dU = -e^{-\theta} d\theta, V = -\frac{1}{2} \cos 2\theta, \text{ so}$$

$$\int e^{-\theta} \sin 2\theta d\theta = -\frac{1}{2}e^{-\theta} \cos 2\theta - \int \left(-\frac{1}{2}\right) \cos 2\theta (-e^{-\theta} d\theta) = -\frac{1}{2}e^{-\theta} \cos 2\theta - \frac{1}{2} \int e^{-\theta} \cos 2\theta d\theta.$$

$$\text{So } I = \frac{1}{2}e^{-\theta} \sin 2\theta + \frac{1}{2} \left[\left(-\frac{1}{2}e^{-\theta} \cos 2\theta\right) - \frac{1}{2}I \right] = \frac{1}{2}e^{-\theta} \sin 2\theta - \frac{1}{4}e^{-\theta} \cos 2\theta - \frac{1}{4}I \Rightarrow$$

$$\frac{5}{4}I = \frac{1}{2}e^{-\theta} \sin 2\theta - \frac{1}{4}e^{-\theta} \cos 2\theta + C_1 \Rightarrow$$

$$I = \frac{4}{5} \left(\frac{1}{2}e^{-\theta} \sin 2\theta - \frac{1}{4}e^{-\theta} \cos 2\theta + C_1 \right) = \frac{2}{5}e^{-\theta} \sin 2\theta - \frac{1}{5}e^{-\theta} \cos 2\theta + C.$$

17. Let $u = y$, $dv = \sinh y dy \Rightarrow du = dy$, $v = \cosh y$. Then

$$\int y \sinh y dy = y \cosh y - \int \cosh y dy = y \cosh y - \sinh y + C.$$

18. Let $u = y$, $dv = \cosh ay dy \Rightarrow du = dy$, $v = \frac{\sinh ay}{a}$. Then

$$\int y \cosh ay dy = \frac{y \sinh ay}{a} - \frac{1}{a} \int \sinh ay dy = \frac{y \sinh ay}{a} - \frac{\cosh ay}{a^2} + C.$$

19. Let $u = t$, $dv = \sin 3t dt \Rightarrow du = dt$, $v = -\frac{1}{3} \cos 3t$. Then

$$\int_0^{\pi} t \sin 3t dt = \left[-\frac{1}{3}t \cos 3t \right]_0^{\pi} + \frac{1}{3} \int_0^{\pi} \cos 3t dt = \left(\frac{1}{3}\pi - 0 \right) + \frac{1}{9} [\sin 3t]_0^{\pi} = \frac{\pi}{3}.$$

20. First let $u = x^2 + 1$, $dv = e^{-x} dx \Rightarrow du = 2x dx$, $v = -e^{-x}$. By (6),

$$\int_0^1 (x^2 + 1)e^{-x} dx = \left[-(x^2 + 1)e^{-x} \right]_0^1 + \int_0^1 2xe^{-x} dx = -2e^{-1} + 1 + 2 \int_0^1 xe^{-x} dx. \text{ Next let}$$

$$U = x, dV = e^{-x} dx \Rightarrow dU = dx, V = -e^{-x}. \text{ By (6) again,}$$

$$\int_0^1 xe^{-x} dx = \left[-xe^{-x} \right]_0^1 + \int_0^1 e^{-x} dx = -e^{-1} + \left[-e^{-x} \right]_0^1 = -e^{-1} - e^{-1} + 1 = -2e^{-1} + 1. \text{ So}$$

$$\int_0^1 (x^2 + 1)e^{-x} dx = -2e^{-1} + 1 + 2(-2e^{-1} + 1) = -2e^{-1} + 1 - 4e^{-1} + 2 = -6e^{-1} + 3.$$

21. Let $u = \ln x$, $dv = x^{-2} dx \Rightarrow du = \frac{1}{x} dx$, $v = -x^{-1}$. By (6),

$$\int_1^2 \frac{\ln x}{x^2} dx = \left[-\frac{\ln x}{x} \right]_1^2 + \int_1^2 x^{-2} dx = -\frac{1}{2} \ln 2 + \ln 1 + \left[-\frac{1}{x} \right]_1^2 = -\frac{1}{2} \ln 2 + 0 - \frac{1}{2} + 1 = \frac{1}{2} - \frac{1}{2} \ln 2.$$

22. Let $u = \ln t$, $dv = \sqrt{t} dt \Rightarrow du = dt/t$, $v = \frac{2}{3}t^{3/2}$. By Formula 6,

$$\int_1^4 \sqrt{t} \ln t dt = \left[\frac{2}{3}t^{3/2} \ln t \right]_1^4 - \frac{2}{3} \int_1^4 \sqrt{t} dt = \frac{2}{3} \cdot 8 \cdot \ln 4 - 0 - \left[\frac{2}{3} \cdot \frac{2}{3}t^{3/2} \right]_1^4 = \frac{16}{3} \ln 4 - \frac{4}{9} (8 - 1) = \frac{16}{3} \ln 4 - \frac{28}{9}.$$

23. Let $u = y$, $dv = \frac{dy}{e^{2y}} = e^{-2y} dy \Rightarrow du = dy$, $v = -\frac{1}{2}e^{-2y}$. Then

$$\int_0^1 \frac{y}{e^{2y}} dy = \left[-\frac{1}{2}ye^{-2y}\right]_0^1 + \frac{1}{2} \int_0^1 e^{-2y} dy = \left(-\frac{1}{2}e^{-2} + 0\right) - \frac{1}{4}\left[e^{-2y}\right]_0^1 = -\frac{1}{2}e^{-2} - \frac{1}{4}e^{-2} + \frac{1}{4} = \frac{1}{4} - \frac{3}{4}e^{-2}.$$

24. Let $u = x$, $dv = \csc^2 x dx \Rightarrow du = dx$, $v = -\cot x$. Then

$$\begin{aligned} \int_{\pi/4}^{\pi/2} x \csc^2 x dx &= [-x \cot x]_{\pi/4}^{\pi/2} + \int_{\pi/4}^{\pi/2} \cot x dx = -\frac{\pi}{2} \cdot 0 + \frac{\pi}{4} \cdot 1 + \left[\ln |\sin x|\right]_{\pi/4}^{\pi/2} \quad [\text{see Exercise 5.5.75}] \\ &= \frac{\pi}{4} + \ln 1 - \ln \frac{1}{\sqrt{2}} = \frac{\pi}{4} + 0 - \ln 2^{-1/2} = \frac{\pi}{4} + \frac{1}{2} \ln 2 \end{aligned}$$

25. Let $u = \cos^{-1} x$, $dv = dx \Rightarrow du = -\frac{dx}{\sqrt{1-x^2}}$, $v = x$. Then

$$\begin{aligned} I &= \int_0^{1/2} \cos^{-1} x dx = [x \cos^{-1} x]_0^{1/2} + \int_0^{1/2} \frac{x dx}{\sqrt{1-x^2}} = \frac{1}{2} \cdot \frac{\pi}{3} + \int_1^{3/4} t^{-1/2} \left[-\frac{1}{2} dt\right], \text{ where } t = 1 - x^2 \\ &\Rightarrow dt = -2x dx. \text{ Thus, } I = \frac{\pi}{6} + \frac{1}{2} \int_{3/4}^1 t^{-1/2} dt = \frac{\pi}{6} + [\sqrt{t}]_{3/4}^1 = \frac{\pi}{6} + 1 - \frac{\sqrt{3}}{2} = \frac{1}{6}(\pi + 6 - 3\sqrt{3}). \end{aligned}$$

26. Let $u = x$, $dv = 5^x dx \Rightarrow du = dx$, $v = (5^x/\ln 5)$. Then

$$\begin{aligned} \int_0^1 x 5^x dx &= \left[\frac{x 5^x}{\ln 5}\right]_0^1 - \int_0^1 \frac{5^x}{\ln 5} dx = \frac{5}{\ln 5} - 0 - \frac{1}{\ln 5} \left[\frac{5^x}{\ln 5}\right]_0^1 = \frac{5}{\ln 5} - \frac{5}{(\ln 5)^2} + \frac{1}{(\ln 5)^2} \\ &= \frac{5}{\ln 5} - \frac{4}{(\ln 5)^2} \end{aligned}$$

27. Let $u = \ln(\sin x)$, $dv = \cos x dx \Rightarrow du = \frac{\cos x}{\sin x} dx$, $v = \sin x$. Then

$$I = \int \cos x \ln(\sin x) dx = \sin x \ln(\sin x) - \int \cos x dx = \sin x \ln(\sin x) - \sin x + C.$$

Another method: Substitute $t = \sin x$, so $dt = \cos x dx$. Then $I = \int \ln t dt = t \ln t - t + C$ (see Example 2) and so $I = \sin x (\ln \sin x - 1) + C$.

28. Let $u = \arctan(1/x)$, $dv = dx \Rightarrow du = \frac{1}{1+(1/x)^2} \cdot \frac{-1}{x^2} dx = \frac{-dx}{x^2+1}$, $v = x$. Then

$$\begin{aligned} \int_1^{\sqrt{3}} \arctan(1/x) dx &= \left[x \arctan\left(\frac{1}{x}\right)\right]_1^{\sqrt{3}} + \int_1^{\sqrt{3}} \frac{x dx}{x^2+1} = \sqrt{3} \frac{\pi}{6} - 1 \cdot \frac{\pi}{4} + \frac{1}{2} [\ln(x^2+1)]_1^{\sqrt{3}} \\ &= \frac{\pi\sqrt{3}}{6} - \frac{\pi}{4} + \frac{1}{2}(\ln 4 - \ln 2) = \frac{\pi\sqrt{3}}{6} - \frac{\pi}{2} + \frac{1}{2} \ln \frac{4}{2} = \frac{\pi\sqrt{3}}{6} - \frac{\pi}{2} + \frac{1}{2} \ln 2 \end{aligned}$$

29. Let $w = \ln x \Rightarrow dw = dx/x$. Then $x = e^w$ and $dx = e^w dw$, so

$$\begin{aligned} \int \cos(\ln x) dx &= \int e^w \cos w dw = \frac{1}{2} e^w (\sin w + \cos w) + C \quad [\text{by the method of Example 4}] \\ &= \frac{1}{2} x [\sin(\ln x) + \cos(\ln x)] + C \end{aligned}$$

30. Let $u = r^2$, $dv = \frac{r}{\sqrt{4+r^2}} dr \Rightarrow du = 2r dr$, $v = \sqrt{4+r^2}$. By (6),

$$\begin{aligned} \int_0^1 \frac{r^3}{\sqrt{4+r^2}} dr &= \left[r^2 \sqrt{4+r^2}\right]_0^1 - 2 \int_0^1 r \sqrt{4+r^2} dr = \sqrt{5} - \frac{2}{3} \left[(4+r^2)^{3/2}\right]_0^1 \\ &= \sqrt{5} - \frac{2}{3}(5)^{3/2} + \frac{2}{3}(8) = \sqrt{5} \left(1 - \frac{10}{3}\right) + \frac{16}{3} = \frac{16}{3} - \frac{7}{3}\sqrt{5} \end{aligned}$$

31. Let $u = (\ln x)^2$, $dv = x^4 dx \Rightarrow du = 2\frac{\ln x}{x} dx$, $v = \frac{x^5}{5}$. By (6),

$$\int_1^2 x^4 (\ln x)^2 dx = \left[\frac{x^5}{5} (\ln x)^2 \right]_1^2 - 2 \int_1^2 \frac{x^4}{5} \ln x dx = \frac{32}{5} (\ln 2)^2 - 0 - 2 \int_1^2 \frac{x^4}{5} \ln x dx.$$

$$\text{Let } U = \ln x, dV = \frac{x^4}{5} dx \Rightarrow dU = \frac{1}{x} dx, V = \frac{x^5}{25}.$$

$$\text{Then } \int_1^2 \frac{x^4}{5} \ln x dx = \left[\frac{x^5}{25} \ln x \right]_1^2 - \int_1^2 \frac{x^4}{25} dx = \frac{32}{25} \ln 2 - 0 - \left[\frac{x^5}{125} \right]_1^2 = \frac{32}{25} \ln 2 - \left(\frac{32}{125} - \frac{1}{125} \right).$$

$$\text{So } \int_1^2 x^4 (\ln x)^2 dx = \frac{32}{5} (\ln 2)^2 - 2 \left(\frac{32}{25} \ln 2 - \frac{31}{125} \right) = \frac{32}{5} (\ln 2)^2 - \frac{64}{25} \ln 2 + \frac{62}{125}.$$

32. Let $u = \sin(t-s)$, $dv = e^s ds \Rightarrow du = -\cos(t-s) ds$, $v = e^s$. Then

$$I = \int_0^t e^s \sin(t-s) ds = [e^s \sin(t-s)]_0^t + \int_0^t e^s \cos(t-s) ds = e^t \sin 0 - e^0 \sin t + I_1. \text{ For}$$

$$I_1, \text{ let } U = \cos(t-s), dV = e^s ds \Rightarrow dU = \sin(t-s) ds, V = e^s. \text{ So}$$

$$I_1 = [e^s \cos(t-s)]_0^t - \int_0^t e^s \sin(t-s) ds = e^t \cos 0 - e^0 \cos t - I. \text{ Thus, } I = -\sin t + e^t - \cos t - I \Rightarrow$$

$$2I = e^t - \cos t - \sin t \Rightarrow I = \frac{1}{2}(e^t - \cos t - \sin t).$$

33. Let $w = \sqrt{x}$, so that $x = w^2$ and $dx = 2w dw$. Thus, $\int \sin \sqrt{x} dx = \int 2w \sin w dw$. Now use parts with $u = 2w$, $dv = \sin w dw$, $du = 2 dw$, $v = -\cos w$ to get

$$\begin{aligned} \int 2w \sin w dw &= -2w \cos w + \int 2 \cos w dw = -2w \cos w + 2 \sin w + C \\ &= -2\sqrt{x} \cos \sqrt{x} + 2 \sin \sqrt{x} + C = 2(\sin \sqrt{x} - \sqrt{x} \cos \sqrt{x}) + C \end{aligned}$$

34. Let $w = \sqrt{x}$, so that $x = w^2$ and $dx = 2w dw$. Thus, $\int_1^4 e^{\sqrt{x}} dx = \int_1^2 e^w 2w dw$. Now use parts with $u = 2w$, $dv = e^w dw$, $du = 2 dw$, $v = e^w$ to get $\int_1^2 e^w 2w dw = [2we^w]_1^2 - 2 \int_1^2 e^w dw = 4e^2 - 2e - 2(e^2 - e) = 2e^2$.

35. Let $x = \theta^2$, so that $dx = 2\theta d\theta$. Thus, $\int_{\sqrt{\pi/2}}^{\sqrt{\pi}} \theta^3 \cos(\theta^2) d\theta = \int_{\sqrt{\pi/2}}^{\sqrt{\pi}} \theta^2 \cos(\theta^2) \cdot \frac{1}{2}(2\theta d\theta) = \frac{1}{2} \int_{\pi/2}^{\pi} x \cos x dx$. Now use parts with $u = x$, $dv = \cos x dx$, $du = dx$, $v = \sin x$ to get

$$\begin{aligned} \frac{1}{2} \int_{\pi/2}^{\pi} x \cos x dx &= \frac{1}{2} ([x \sin x]_{\pi/2}^{\pi} - \int_{\pi/2}^{\pi} \sin x dx) = \frac{1}{2} [x \sin x + \cos x]_{\pi/2}^{\pi} \\ &= \frac{1}{2} (\pi \sin \pi + \cos \pi) - \frac{1}{2} \left(\frac{\pi}{2} \sin \frac{\pi}{2} + \cos \frac{\pi}{2} \right) = \frac{1}{2} (\pi \cdot 0 - 1) - \frac{1}{2} \left(\frac{\pi}{2} \cdot 1 + 0 \right) = -\frac{1}{2} - \frac{\pi}{4} \end{aligned}$$

36. $\int x^5 e^{x^2} dx = \int (x^2)^2 e^{x^2} x dx = \int t^2 e^t \frac{1}{2} dt$ [where $t = x^2 \Rightarrow \frac{1}{2} dt = x dx$]
 $= \frac{1}{2} (t^2 - 2t + 2) e^t + C$ [by Example 3] $= \frac{1}{2} (x^4 - 2x^2 + 2) e^{x^2} + C$

In Exercises 37–40, let $f(x)$ denote the integrand and $F(x)$ its antiderivative (with $C = 0$).

37. Let $u = x$, $dv = \cos \pi x dx \Rightarrow du = dx$, $v = (\sin \pi x) / \pi$. Then

$$\int x \cos \pi x dx = x \cdot \frac{\sin \pi x}{\pi} - \int \frac{\sin \pi x}{\pi} dx = \frac{x \sin \pi x}{\pi} + \frac{\cos \pi x}{\pi^2} + C.$$

We see from the graph that this is reasonable, since F has extreme values where f is 0.

38. Let $u = \ln x$, $dv = x^{3/2} dx \Rightarrow du = \frac{1}{x} dx$, $v = \frac{2}{5}x^{5/2}$. Then

$$\begin{aligned}\int x^{3/2} \ln x \, dx &= \frac{2}{5}x^{5/2} \ln x - \frac{2}{5} \int x^{3/2} dx = \frac{2}{5}x^{5/2} \ln x - \left(\frac{2}{5}\right)^2 x^{5/2} + C \\ &= \frac{2}{5}x^{5/2} \ln x - \frac{4}{25}x^{5/2} + C.\end{aligned}$$

We see from the graph that this is reasonable, since F has a minimum where f changes from negative to positive.

39. Let $u = 2x + 3$, $dv = e^x dx \Rightarrow du = 2 dx$, $v = e^x$. Then

$$\begin{aligned}\int (2x + 3)e^x \, dx &= (2x + 3)e^x - 2 \int e^x dx = (2x + 3)e^x - 2e^x + C = \\ &= (2x + 1)e^x + C. \text{ We see from the graph that this is reasonable, since } F \\ &\text{has a minimum where } f \text{ changes from negative to positive.}\end{aligned}$$

40. $\int x^3 e^{x^2} dx = \int x^2 \cdot x e^{x^2} dx = I$.

Let $u = x^2$, $dv = x e^{x^2} dx \Rightarrow du = 2x dx$, $v = \frac{1}{2}e^{x^2}$. Then

$$I = \frac{1}{2}x^2 e^{x^2} - \int x e^{x^2} dx = \frac{1}{2}x^2 e^{x^2} - \frac{1}{2}e^{x^2} + C = \frac{1}{2}e^{x^2}(x^2 - 1) + C.$$

We see from the graph that this is reasonable, since F has a minimum where f changes from negative to positive.

41. (a) Take $n = 2$ in Example 6 to get $\int \sin^2 x \, dx = -\frac{1}{2} \cos x \sin x + \frac{1}{2} \int 1 \, dx = \frac{x}{2} - \frac{\sin 2x}{4} + C$.

$$(b) \int \sin^4 x \, dx = -\frac{1}{4} \cos x \sin^3 x + \frac{3}{4} \int \sin^2 x \, dx = -\frac{1}{4} \cos x \sin^3 x + \frac{3}{8}x - \frac{3}{16} \sin 2x + C.$$

42. (a) Let $u = \cos^{n-1} x$, $dv = \cos x \, dx \Rightarrow du = -(n-1) \cos^{n-2} x \sin x \, dx$, $v = \sin x$ in (2):

$$\begin{aligned}\int \cos^n x \, dx &= \cos^{n-1} x \sin x + (n-1) \int \cos^{n-2} x \sin^2 x \, dx \\ &= \cos^{n-1} x \sin x + (n-1) \int \cos^{n-2} x (1 - \cos^2 x) \, dx \\ &= \cos^{n-1} x \sin x + (n-1) \int \cos^{n-2} x \, dx - (n-1) \int \cos^n x \, dx\end{aligned}$$

Rearranging terms gives $n \int \cos^n x \, dx = \cos^{n-1} x \sin x + (n-1) \int \cos^{n-2} x \, dx$ or

$$\int \cos^n x \, dx = \frac{1}{n} \cos^{n-1} x \sin x + \frac{n-1}{n} \int \cos^{n-2} x \, dx$$

- (b) Take $n = 2$ in part (a) to get $\int \cos^2 x \, dx = \frac{1}{2} \cos x \sin x + \frac{1}{2} \int 1 \, dx = \frac{x}{2} + \frac{\sin 2x}{4} + C$.

$$(c) \int \cos^4 x \, dx = \frac{1}{4} \cos^3 x \sin x + \frac{3}{4} \int \cos^2 x \, dx = \frac{1}{4} \cos^3 x \sin x + \frac{3}{8}x + \frac{3}{16} \sin 2x + C$$

43. (a) From Example 6, $\int \sin^n x \, dx = -\frac{1}{n} \cos x \sin^{n-1} x + \frac{n-1}{n} \int \sin^{n-2} x \, dx$. Using (6),

$$\begin{aligned}\int_0^{\pi/2} \sin^n x \, dx &= \left[-\frac{\cos x \sin^{n-1} x}{n} \right]_0^{\pi/2} + \frac{n-1}{n} \int_0^{\pi/2} \sin^{n-2} x \, dx \\ &= (0 - 0) + \frac{n-1}{n} \int_0^{\pi/2} \sin^{n-2} x \, dx = \frac{n-1}{n} \int_0^{\pi/2} \sin^{n-2} x \, dx\end{aligned}$$

(b) Using $n = 3$ in part (a), we have $\int_0^{\pi/2} \sin^3 x \, dx = \frac{2}{3} \int_0^{\pi/2} \sin x \, dx = \left[-\frac{2}{3} \cos x\right]_0^{\pi/2} = \frac{2}{3}$.

Using $n = 5$ in part (a), we have $\int_0^{\pi/2} \sin^5 x \, dx = \frac{4}{5} \int_0^{\pi/2} \sin^3 x \, dx = \frac{4}{5} \cdot \frac{2}{3} = \frac{8}{15}$.

(c) The formula holds for $n = 1$ (that is, $2n + 1 = 3$) by (b). Assume it holds for some $k \geq 1$. Then

$$\int_0^{\pi/2} \sin^{2k+1} x \, dx = \frac{2 \cdot 4 \cdot 6 \cdots (2k)}{3 \cdot 5 \cdot 7 \cdots (2k+1)}. \text{ By Example 6,}$$

$$\begin{aligned} \int_0^{\pi/2} \sin^{2k+3} x \, dx &= \frac{2k+2}{2k+3} \int_0^{\pi/2} \sin^{2k+1} x \, dx = \frac{2k+2}{2k+3} \cdot \frac{2 \cdot 4 \cdot 6 \cdots (2k)}{3 \cdot 5 \cdot 7 \cdots (2k+1)} \\ &= \frac{2 \cdot 4 \cdot 6 \cdots (2k)[2(k+1)]}{3 \cdot 5 \cdot 7 \cdots (2k+1)[2(k+1)+1]}, \end{aligned}$$

so the formula holds for $n = k + 1$. By induction, the formula holds for all $n \geq 1$.

44. Using Exercise 43(a), we see that the formula holds for $n = 1$, because

$$\int_0^{\pi/2} \sin^2 x \, dx = \frac{1}{2} \int_0^{\pi/2} 1 \, dx = \frac{1}{2} \left[x\right]_0^{\pi/2} = \frac{1}{2} \cdot \frac{\pi}{2}.$$

Now assume it holds for some $k \geq 1$. Then $\int_0^{\pi/2} \sin^{2k} x \, dx = \frac{1 \cdot 3 \cdot 5 \cdots (2k-1)}{2 \cdot 4 \cdot 6 \cdots (2k)} \frac{\pi}{2}$. By Exercise 43(a),

$$\begin{aligned} \int_0^{\pi/2} \sin^{2(k+1)} x \, dx &= \frac{2k+1}{2k+2} \int_0^{\pi/2} \sin^{2k} x \, dx = \frac{2k+1}{2k+2} \cdot \frac{1 \cdot 3 \cdot 5 \cdots (2k-1)}{2 \cdot 4 \cdot 6 \cdots (2k)} \frac{\pi}{2} \\ &= \frac{1 \cdot 3 \cdot 5 \cdots (2k-1)(2k+1)}{2 \cdot 4 \cdot 6 \cdots (2k)(2k+2)} \cdot \frac{\pi}{2}, \end{aligned}$$

so the formula holds for $n = k + 1$. By induction, the formula holds for all $n \geq 1$.

45. Let $u = (\ln x)^n$, $dv = dx \Rightarrow du = n(\ln x)^{n-1}(dx/x)$, $v = x$. By Equation 2,

$$\int (\ln x)^n dx = x(\ln x)^n - \int n x (\ln x)^{n-1} (dx/x) = x(\ln x)^n - n \int (\ln x)^{n-1} dx.$$

46. Let $u = x^n$, $dv = e^x dx \Rightarrow du = nx^{n-1} dx$, $v = e^x$. By Equation 2, $\int x^n e^x dx = x^n e^x - n \int x^{n-1} e^x dx$.

47. Let $u = (x^2 + a^2)^n$, $dv = dx \Rightarrow du = n(x^2 + a^2)^{n-1} 2x dx$, $v = x$. Then

$$\begin{aligned} \int (x^2 + a^2)^n dx &= x(x^2 + a^2)^n - 2n \int x^2 (x^2 + a^2)^{n-1} dx \\ &= x(x^2 + a^2)^n - 2n \left[\int (x^2 + a^2)^n dx - a^2 \int (x^2 + a^2)^{n-1} dx \right] \quad [\text{since } x^2 = (x^2 + a^2) - a^2] \\ \Rightarrow (2n+1) \int (x^2 + a^2)^n dx &= x(x^2 + a^2)^n + 2na^2 \int (x^2 + a^2)^{n-1} dx, \text{ and} \\ \int (x^2 + a^2)^n dx &= \frac{x(x^2 + a^2)^n}{2n+1} + \frac{2na^2}{2n+1} \int (x^2 + a^2)^{n-1} dx \quad [\text{provided } 2n+1 \neq 0]. \end{aligned}$$

48. Let $u = \sec^{n-2} x$, $dv = \sec^2 x dx \Rightarrow du = (n-2) \sec^{n-3} x \sec x \tan x dx$, $v = \tan x$. Then by Equation 2,

$$\begin{aligned} \int \sec^n x dx &= \tan x \sec^{n-2} x - (n-2) \int \sec^{n-2} x \tan^2 x dx \\ &= \tan x \sec^{n-2} x - (n-2) \int \sec^{n-2} x (\sec^2 x - 1) dx \\ &= \tan x \sec^{n-2} x - (n-2) \int \sec^n x dx + (n-2) \int \sec^{n-2} x dx \end{aligned}$$

so $(n-1) \int \sec^n x dx = \tan x \sec^{n-2} x + (n-2) \int \sec^{n-2} x dx$. If $n-1 \neq 0$, then

$$\int \sec^n x dx = \frac{\tan x \sec^{n-2} x}{n-1} + \frac{n-2}{n-1} \int \sec^{n-2} x dx.$$

49. Take
- $n = 3$
- in Exercise 45 to get

$$\int (\ln x)^3 dx = x(\ln x)^3 - 3 \int (\ln x)^2 dx = x(\ln x)^3 - 3x(\ln x)^2 + 6x \ln x - 6x + C \quad [\text{by Exercise 13}].$$

Or: Instead of using Exercise 13, apply Exercise 45 again with $n = 2$.

50. Take
- $n = 4$
- in Exercise 46 to get

$$\begin{aligned} \int x^4 e^x dx &= x^4 e^x - 4 \int x^3 e^x dx = x^4 e^x - 4(x^3 - 3x^2 + 6x - 6)e^x + C \quad [\text{by Exercise 14}] \\ &= e^x(x^4 - 4x^3 + 12x^2 - 24x + 24) + C \end{aligned}$$

Or: Instead of using Exercise 14, apply Exercise 46 with $n = 3$, then $n = 2$, then $n = 1$.

51. Area =
- $\int_0^5 x e^{-0.4x} dx$
- . Let
- $u = x$
- ,
- $dv = e^{-0.4x} dx \Rightarrow$

$$du = dx, v = -2.5e^{-0.4x}. \text{ Then}$$

$$\begin{aligned} \text{area} &= [-2.5x e^{-0.4x}]_0^5 + 2.5 \int_0^5 e^{-0.4x} dx \\ &= -12.5e^{-2} + 0 + 2.5[-2.5e^{-0.4x}]_0^5 \\ &= -12.5e^{-2} - 6.25(e^{-2} - 1) = 6.25 - 18.75e^{-2} \quad \text{or} \quad \frac{25}{4} - \frac{75}{4}e^{-2} \end{aligned}$$

52. The curves $y = x \ln x$ and $y = 5 \ln x$ intersect when $x \ln x = 5 \ln x \Leftrightarrow x \ln x - 5 \ln x = 0 \Leftrightarrow (x - 5) \ln x = 0$; that is, when $x = 1$ or $x = 5$. For $1 < x < 5$, we have $5 \ln x > x \ln x$ since $\ln x > 0$. Thus,
- $$\text{area} = \int_1^5 (5 \ln x - x \ln x) dx = \int_1^5 [(5 - x) \ln x] dx. \text{ Let } u = \ln x, dv = (5 - x) dx \Rightarrow du = dx/x,$$
- $$v = 5x - \frac{1}{2}x^2. \text{ Then}$$

$$\begin{aligned} \text{area} &= [(\ln x)(5x - \frac{1}{2}x^2)]_1^5 - \int_1^5 [(5x - \frac{1}{2}x^2) \frac{1}{x}] dx = (\ln 5)(\frac{25}{2}) - 0 - \int_1^5 (5 - \frac{1}{2}x) dx \\ &= \frac{25}{2} \ln 5 - [5x - \frac{1}{4}x^2]_1^5 = \frac{25}{2} \ln 5 - [(25 - \frac{25}{4}) - (5 - \frac{1}{4})] = \frac{25}{2} \ln 5 - 14 \end{aligned}$$

53. The curves $y = x \sin x$ and $y = (x - 2)^2$ intersect at $a \approx 1.04748$ and $b \approx 2.87307$, so

$$\begin{aligned} \text{area} &= \int_a^b [x \sin x - (x - 2)^2] dx \\ &= [-x \cos x + \sin x - \frac{1}{3}(x - 2)^3]_a^b \quad [\text{by Example 1}] \\ &\approx 2.81358 - 0.63075 = 2.18283 \end{aligned}$$

54. The curves $y = \arctan 3x$ and $y = x/2$ intersect at $x = \pm a \approx \pm 2.91379$, so

$$\begin{aligned} \text{area} &= \int_{-a}^a |\arctan 3x - \frac{1}{2}x| dx = 2 \int_0^a (\arctan 3x - \frac{1}{2}x) dx \\ &= 2[x \arctan 3x - \frac{1}{6} \ln(1 + 9x^2) - \frac{1}{4}x^2]_0^a \quad [\text{see Example 5}] \\ &\approx 2(1.39768) = 2.79536. \end{aligned}$$

55. $V = \int_0^1 2\pi x \cos(\pi x/2) dx$. Let $u = x$, $dv = \cos(\pi x/2) dx \Rightarrow du = dx, v = \frac{2}{\pi} \sin(\pi x/2)$.

$$\begin{aligned} V &= 2\pi \left[\frac{2}{\pi} x \sin\left(\frac{\pi x}{2}\right) \right]_0^1 - 2\pi \cdot \frac{2}{\pi} \int_0^1 \sin\left(\frac{\pi x}{2}\right) dx = 2\pi \left(\frac{2}{\pi} - 0 \right) - 4 \left[-\frac{2}{\pi} \cos\left(\frac{\pi x}{2}\right) \right]_0^1 \\ &= 4 + \frac{8}{\pi}(0 - 1) = 4 - \frac{8}{\pi}. \end{aligned}$$

$$56. \text{Volume} = \int_0^1 2\pi x(e^x - e^{-x}) dx = 2\pi \int_0^1 (xe^x - xe^{-x}) dx$$

$$= 2\pi \left[\int_0^1 xe^x dx - \int_0^1 xe^{-x} dx \right] \quad [\text{both integrals by parts}]$$

$$= 2\pi [(xe^x - e^x) - (-xe^{-x} - e^{-x})]_0^1 = 2\pi [2/e - 0] = 4\pi/e$$

$$57. \text{Volume} = \int_{-1}^0 2\pi(1-x)e^{-x} dx. \text{ Let } u = 1-x, dv = e^{-x} dx \Rightarrow du = -dx, v = -e^{-x}.$$

$$V = 2\pi [(1-x)(-e^{-x})]_{-1}^0 - 2\pi \int_{-1}^0 e^{-x} dx = 2\pi [(x-1)(e^{-x}) + e^{-x}]_{-1}^0$$

$$= 2\pi [xe^{-x}]_{-1}^0 = 2\pi(0 + e) = 2\pi e$$

$$58. \text{Volume} = \int_1^\pi 2\pi y \cdot \ln y dy = 2\pi \left[\frac{1}{2} y^2 \ln y - \frac{1}{4} y^2 \right]_1^\pi \quad [\text{by parts with } u = \ln y \text{ and } dv = y dy]$$

$$= 2\pi \left[\frac{1}{4} y^2 (2 \ln y - 1) \right]_1^\pi = 2\pi \left[\frac{\pi^2 (2 \ln \pi - 1)}{4} - \frac{(0-1)}{4} \right] = \pi^3 \ln \pi - \frac{\pi^3}{2} + \frac{\pi}{2}$$

$$59. \text{The average value of } f(x) = x^2 \ln x \text{ on the interval } [1, 3] \text{ is } f_{\text{ave}} = \frac{1}{3-1} \int_1^3 x^2 \ln x dx = \frac{1}{2} I.$$

$$\text{Let } u = \ln x, dv = x^2 dx \Rightarrow du = (1/x) dx, v = \frac{1}{3} x^3. \text{ So}$$

$$I = \left[\frac{1}{3} x^3 \ln x \right]_1^3 - \int_1^3 \frac{1}{3} x^2 dx = (9 \ln 3 - 0) - \left[\frac{1}{9} x^3 \right]_1^3 = 9 \ln 3 - (3 - \frac{1}{9}) = 9 \ln 3 - \frac{26}{9}.$$

$$\text{Thus, } f_{\text{ave}} = \frac{1}{2} I = \frac{1}{2} (9 \ln 3 - \frac{26}{9}) = \frac{9}{2} \ln 3 - \frac{13}{9}.$$

$$60. \text{The rocket will have height } H = \int_0^{60} v(t) dt \text{ after 60 seconds.}$$

$$H = \int_0^{60} \left[-gt - v_e \ln \left(\frac{m-rt}{m} \right) \right] dt = -g \left[\frac{1}{2} t^2 \right]_0^{60} - v_e \left[\int_0^{60} \ln(m-rt) dt - \int_0^{60} \ln m dt \right]$$

$$= -g(1800) + v_e(\ln m)(60) - v_e \int_0^{60} \ln(m-rt) dt$$

$$\text{Let } u = \ln(m-rt), dv = dt \Rightarrow du = \frac{1}{m-rt}(-r) dt, v = t. \text{ Then}$$

$$\int_0^{60} \ln(m-rt) dt = [t \ln(m-rt)]_0^{60} + \int_0^{60} \frac{rt}{m-rt} dt = 60 \ln(m-60r) + \int_0^{60} \left(-1 + \frac{m}{m-rt} \right) dt$$

$$= 60 \ln(m-60r) + \left[-t - \frac{m}{r} \ln(m-rt) \right]_0^{60}$$

$$= 60 \ln(m-60r) - 60 - \frac{m}{r} \ln(m-60r) + \frac{m}{r} \ln m$$

$$\text{So } H = -1800g + 60v_e \ln m - 60v_e \ln(m-60r) + 60v_e + \frac{m}{r} v_e \ln(m-60r) - \frac{m}{r} v_e \ln m. \text{ Substituting } g = 9.8, m = 30,000, r = 160, \text{ and } v_e = 3000 \text{ gives us } H \approx 14,844 \text{ m.}$$

$$61. \text{Since } v(t) > 0 \text{ for all } t, \text{ the desired distance is } s(t) = \int_0^t v(w) dw = \int_0^t w^2 e^{-w} dw.$$

$$\text{First let } u = w^2, dv = e^{-w} dw \Rightarrow du = 2w dw, v = -e^{-w}. \text{ Then } s(t) = [-w^2 e^{-w}]_0^t + 2 \int_0^t w e^{-w} dw.$$

$$\text{Next let } U = w, dV = e^{-w} dw \Rightarrow dU = dw, V = -e^{-w}. \text{ Then}$$

$$s(t) = -t^2 e^{-t} + 2 \left([-w e^{-w}]_0^t + \int_0^t e^{-w} dw \right) = -t^2 e^{-t} + 2 \left(-t e^{-t} + 0 + [-e^{-w}]_0^t \right)$$

$$= -t^2 e^{-t} + 2(-t e^{-t} - e^{-t} + 1) = -t^2 e^{-t} - 2t e^{-t} - 2e^{-t} + 2$$

$$= 2 - e^{-t}(t^2 + 2t + 2) \text{ meters}$$

62. Suppose $f(0) = g(0) = 0$ and let $u = f(x)$, $dv = g''(x) dx \Rightarrow du = f'(x) dx$, $v = g'(x)$.

Then $\int_0^a f(x)g''(x) dx = [f(x)g'(x)]_0^a - \int_0^a f'(x)g'(x) dx = f(a)g'(a) - \int_0^a f'(x)g'(x) dx$.

Now let $U = f'(x)$, $dV = g'(x) dx \Rightarrow dU = f''(x) dx$ and $V = g(x)$, so

$$\int_0^a f'(x)g'(x) dx = [f'(x)g(x)]_0^a - \int_0^a f''(x)g(x) dx = f'(a)g(a) - \int_0^a f''(x)g(x) dx.$$

Combining the two results, we get $\int_0^a f(x)g''(x) dx = f(a)g'(a) - f'(a)g(a) + \int_0^a f''(x)g(x) dx$.

63. For $I = \int_1^4 xf''(x) dx$, let $u = x$, $dv = f''(x) dx \Rightarrow du = dx$, $v = f'(x)$. Then

$$I = [xf'(x)]_1^4 - \int_1^4 f'(x) dx = 4f'(4) - 1 \cdot f'(1) - [f(4) - f(1)] = 4 \cdot 3 - 1 \cdot 5 - (7 - 2) = 12 - 5 - 5 = 2.$$

We used the fact that f'' is continuous to guarantee that I exists.

64. (a) Take $g(x) = x$ and $g'(x) = 1$ in Equation 1.

(b) By part (a), $\int_a^b f(x) dx = bf(b) - af(a) - \int_a^b xf'(x) dx$. Now let $y = f(x)$, so that $x = g(y)$ and

$dy = f'(x) dx$. Then $\int_a^b xf'(x) dx = \int_{f(a)}^{f(b)} g(y) dy$. The result follows.

(c) Part (b) says that the area of region $ABFC$ is

$$\begin{aligned} &= bf(b) - af(a) - \int_{f(a)}^{f(b)} g(y) dy \\ &= (\text{area of rectangle } OBF E) - (\text{area of rectangle } OACD) - (\text{area of region } DCFE) \end{aligned}$$

(d) We have $f(x) = \ln x$, so $f^{-1}(x) = e^x$, and since $g = f^{-1}$, we have $g(y) = e^y$. By part (b),

$$\int_1^e \ln x dx = e \ln e - 1 \ln 1 - \int_{\ln 1}^{\ln e} e^y dy = e - \int_0^1 e^y dy = e - [e^y]_0^1 = e - (e - 1) = 1.$$

65. Using the formula for volumes of rotation and the figure, we see that

Volume $= \int_0^d \pi b^2 dy - \int_0^c \pi a^2 dy - \int_c^d \pi [g(y)]^2 dy = \pi b^2 d - \pi a^2 c - \int_c^d \pi [g(y)]^2 dy$. Let $y = f(x)$, which gives $dy = f'(x) dx$ and $g(y) = x$, so that $V = \pi b^2 d - \pi a^2 c - \pi \int_a^b x^2 f'(x) dx$. Now integrate

by parts with $u = x^2$, and $dv = f'(x) dx \Rightarrow du = 2x dx$, $v = f(x)$, and

$$\begin{aligned} \int_a^b x^2 f'(x) dx &= [x^2 f(x)]_a^b - \int_a^b 2x f(x) dx = b^2 f(b) - a^2 f(a) - \int_a^b 2x f(x) dx, \text{ but } f(a) = c \text{ and } f(b) = d \\ \Rightarrow V &= \pi b^2 d - \pi a^2 c - \pi [b^2 d - a^2 c - \int_a^b 2x f(x) dx] = \pi \int_a^b 2x f(x) dx. \end{aligned}$$

66. (a) We note that for $0 \leq x \leq \frac{\pi}{2}$, $0 \leq \sin x \leq 1$, so $\sin^{2n+2} x \leq \sin^{2n+1} x \leq \sin^{2n} x$. So by the second Comparison Property of the Integral, $I_{2n+2} \leq I_{2n+1} \leq I_{2n}$.

(b) Substituting directly into the result from Exercise 44, we get

$$\frac{I_{2n+2}}{I_{2n}} = \frac{\frac{1 \cdot 3 \cdot 5 \cdots [2(n+1)-1]}{2 \cdot 4 \cdot 6 \cdots [2(n+1)]} \frac{\pi}{2}}{\frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \frac{\pi}{2}} = \frac{2(n+1)-1}{2(n+1)} = \frac{2n+1}{2n+2}$$

(c) We divide the result from part (a) by I_{2n} . The inequalities are preserved since I_{2n} is positive:

$\frac{I_{2n+2}}{I_{2n}} \leq \frac{I_{2n+1}}{I_{2n}} \leq \frac{I_{2n}}{I_{2n}}$. Now from part (b), the left term is equal to $\frac{2n+1}{2n+2}$, so the expression becomes $\frac{2n+1}{2n+2} \leq \frac{I_{2n+1}}{I_{2n}} \leq 1$. Now $\lim_{n \rightarrow \infty} \frac{2n+1}{2n+2} = \lim_{n \rightarrow \infty} 1 = 1$, so by the Squeeze Theorem, $\lim_{n \rightarrow \infty} \frac{I_{2n+1}}{I_{2n}} = 1$.

(d) We substitute the results from Exercises 43 and 44 into the result from part (c):

$$\begin{aligned} 1 &= \lim_{n \rightarrow \infty} \frac{I_{2n+1}}{I_{2n}} = \lim_{n \rightarrow \infty} \frac{\frac{2 \cdot 4 \cdot 6 \cdots (2n)}{3 \cdot 5 \cdot 7 \cdots (2n+1)}}{\frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} \frac{\pi}{2}} \\ &= \lim_{n \rightarrow \infty} \left[\frac{2 \cdot 4 \cdot 6 \cdots (2n)}{3 \cdot 5 \cdot 7 \cdots (2n+1)} \right] \left[\frac{2 \cdot 4 \cdot 6 \cdots (2n)}{1 \cdot 3 \cdot 5 \cdots (2n-1)} \left(\frac{2}{\pi} \right) \right] \\ &= \lim_{n \rightarrow \infty} \frac{2}{1} \cdot \frac{2}{3} \cdot \frac{4}{3} \cdot \frac{4}{5} \cdot \frac{6}{5} \cdot \frac{6}{7} \cdots \frac{2n}{2n-1} \cdot \frac{2n}{2n+1} \cdot \frac{2}{\pi} \quad [\text{rearrange terms}] \end{aligned}$$

Multiplying both sides by $\frac{\pi}{2}$ gives us the *Wallis product*:

$$\frac{\pi}{2} = \frac{2}{1} \cdot \frac{2}{3} \cdot \frac{4}{3} \cdot \frac{4}{5} \cdot \frac{6}{5} \cdot \frac{6}{7} \cdots$$

(e) The area of the k th rectangle is k . At the $2n$ th step, the area is increased from $2n - 1$ to $2n$ by multiplying the width by $\frac{2n}{2n - 1}$, and at the $(2n + 1)$ th step, the area is increased from $2n$ to $2n + 1$ by multiplying the height by $\frac{2n + 1}{2n}$. These two steps multiply the ratio of width to height by $\frac{2n}{2n - 1}$ and $\frac{1}{(2n + 1)/(2n)} = \frac{2n}{2n + 1}$ respectively. So, by part (d), the limiting ratio is $\frac{2}{1} \cdot \frac{2}{3} \cdot \frac{4}{3} \cdot \frac{4}{5} \cdot \frac{6}{5} \cdot \frac{6}{7} \cdots = \frac{\pi}{2}$.

8.2 Trigonometric Integrals

The symbols $\stackrel{s}{=}$ and $\stackrel{c}{=}$ indicate the use of the substitutions $\{u = \sin x, du = \cos x \, dx\}$ and $\{u = \cos x, du = -\sin x \, dx\}$, respectively.

$$\begin{aligned} 1. \int \sin^3 x \cos^2 x \, dx &= \int \sin^2 x \cos^2 x \sin x \, dx = \int (1 - \cos^2 x) \cos^2 x \sin x \, dx \stackrel{c}{=} \int (1 - u^2) u^2 (-du) \\ &= \int (u^2 - 1) u^2 \, du = \int (u^4 - u^2) \, du = \frac{1}{5} u^5 - \frac{1}{3} u^3 + C = \frac{1}{5} \cos^5 x - \frac{1}{3} \cos^3 x + C \end{aligned}$$

$$\begin{aligned} 2. \int \sin^6 x \cos^3 x \, dx &= \int \sin^6 x \cos^2 x \cos x \, dx = \int \sin^6 x (1 - \sin^2 x) \cos x \, dx \stackrel{s}{=} \int u^6 (1 - u^2) \, du \\ &= \int (u^6 - u^8) \, du = \frac{1}{7}u^7 - \frac{1}{9}u^9 + C = \frac{1}{7}\sin^7 x - \frac{1}{9}\sin^9 x + C \end{aligned}$$

$$\begin{aligned} \mathbf{3.} \quad \int_{\pi/2}^{3\pi/4} \sin^5 x \cos^3 x \, dx &= \int_{\pi/2}^{3\pi/4} \sin^5 x \cos^2 x \cos x \, dx = \int_{\pi/2}^{3\pi/4} \sin^5 x (1 - \sin^2 x) \cos x \, dx \\ &\stackrel{s}{=} \int_1^{\sqrt{2}/2} u^5 (1 - u^2) \, du = \int_1^{\sqrt{2}/2} (u^5 - u^7) \, du = \left[\frac{1}{6} u^6 - \frac{1}{8} u^8 \right]_1^{\sqrt{2}/2} \\ &= \left(\frac{1}{6} - \frac{1/16}{8} \right) - \left(\frac{1}{6} - \frac{1}{8} \right) = -\frac{11}{384} \end{aligned}$$

$$\begin{aligned} 36. \int_{\pi/4}^{\pi/2} \cot^3 x \, dx &= \int_{\pi/4}^{\pi/2} \cot x (\csc^2 x - 1) \, dx = \int_{\pi/4}^{\pi/2} \cot x \csc^2 x \, dx - \int_{\pi/4}^{\pi/2} \frac{\cos x}{\sin x} \, dx \\ &= \left[-\frac{1}{2} \cot^2 x - \ln |\sin x| \right]_{\pi/4}^{\pi/2} = (0 - \ln 1) - \left[-\frac{1}{2} - \ln \frac{1}{\sqrt{2}} \right] = \frac{1}{2} + \ln \frac{1}{\sqrt{2}} = \frac{1}{2}(1 - \ln 2) \end{aligned}$$

$$\begin{aligned} 37. \int \cot^3 \alpha \csc^3 \alpha \, d\alpha &= \int \cot^2 \alpha \csc^2 \alpha \cdot \csc \alpha \cot \alpha \, d\alpha = \int (\csc^2 \alpha - 1) \csc^2 \alpha \cdot \csc \alpha \cot \alpha \, d\alpha \\ &= \int (u^2 - 1)u^2 \cdot (-du) \quad [u = \csc \alpha, du = -\csc \alpha \cot \alpha \, d\alpha] \\ &= \int (u^2 - u^4) \, du = \frac{1}{3}u^3 - \frac{1}{5}u^5 + C = \frac{1}{3}\csc^3 \alpha - \frac{1}{5}\csc^5 \alpha + C \end{aligned}$$

$$\begin{aligned} 38. \int \csc^4 x \cot^6 x \, dx &= \int \cot^6 x (\cot^2 x + 1) \csc^2 x \, dx \\ &= \int u^6(u^2 + 1) \cdot (-du) \quad [u = \cot x, du = -\csc^2 x \, dx] \\ &= \int (-u^8 - u^6) \, du = -\frac{1}{9}u^9 - \frac{1}{7}u^7 + C = -\frac{1}{9}\cot^9 x - \frac{1}{7}\cot^7 x + C \end{aligned}$$

$$\begin{aligned} 39. I = \int \csc x \, dx &= \int \frac{\csc x (\csc x - \cot x)}{\csc x - \cot x} \, dx = \int \frac{-\csc x \cot x + \csc^2 x}{\csc x - \cot x} \, dx. \text{ Let } u = \csc x - \cot x \Rightarrow \\ du &= (-\csc x \cot x + \csc^2 x) \, dx. \text{ Then } I = \int du/u = \ln |u| = \ln |\csc x - \cot x| + C. \end{aligned}$$

$$\begin{aligned} 40. \text{ Let } u = \csc x, dv = \csc^2 x \, dx. \text{ Then } du = -\csc x \cot x \, dx, v = -\cot x \Rightarrow \\ \int \csc^3 x \, dx &= -\csc x \cot x - \int \csc x \cot^2 x \, dx = -\csc x \cot x - \int \csc x (\csc^2 x - 1) \, dx \\ &= -\csc x \cot x + \int \csc x \, dx - \int \csc^3 x \, dx \end{aligned}$$

Solving for $\int \csc^3 x \, dx$ and using Exercise 39, we get

$$\int \csc^3 x \, dx = -\frac{1}{2} \csc x \cot x + \frac{1}{2} \int \csc x \, dx = -\frac{1}{2} \csc x \cot x + \frac{1}{2} \ln |\csc x - \cot x| + C. \text{ Thus,}$$

$$\begin{aligned} \int_{\pi/6}^{\pi/3} \csc^3 x \, dx &= \left[-\frac{1}{2} \csc x \cot x + \frac{1}{2} \ln |\csc x - \cot x| \right]_{\pi/6}^{\pi/3} \\ &= -\frac{1}{2} \cdot \frac{2}{\sqrt{3}} \cdot \frac{1}{\sqrt{3}} + \frac{1}{2} \ln \left| \frac{2}{\sqrt{3}} - \frac{1}{\sqrt{3}} \right| + \frac{1}{2} \cdot 2 \cdot \sqrt{3} - \frac{1}{2} \ln |2 - \sqrt{3}| \\ &= -\frac{1}{3} + \sqrt{3} + \frac{1}{2} \ln \frac{1}{\sqrt{3}} - \frac{1}{2} \ln (2 - \sqrt{3}) \approx 1.7825 \end{aligned}$$

41. Use Equation 2(b):

$$\begin{aligned} \int \sin 5x \sin 2x \, dx &= \int \frac{1}{2} [\cos(5x - 2x) - \cos(5x + 2x)] \, dx = \frac{1}{2} \int (\cos 3x - \cos 7x) \, dx \\ &= \frac{1}{6} \sin 3x - \frac{1}{14} \sin 7x + C \end{aligned}$$

42. Use Equation 2(a):

$$\begin{aligned} \int \sin 3x \cos x \, dx &= \int \frac{1}{2} [\sin(3x + x) + \sin(3x - x)] \, dx = \frac{1}{2} \int (\sin 4x + \sin 2x) \, dx \\ &= -\frac{1}{8} \cos 4x - \frac{1}{4} \cos 2x + C \end{aligned}$$

43. Use Equation 2(c):

$$\begin{aligned} \int \cos 7\theta \cos 5\theta \, d\theta &= \int \frac{1}{2} [\cos(7\theta - 5\theta) + \cos(7\theta + 5\theta)] \, d\theta = \frac{1}{2} \int (\cos 2\theta + \cos 12\theta) \, d\theta \\ &= \frac{1}{2} \left(\frac{1}{2} \sin 2\theta + \frac{1}{12} \sin 12\theta \right) + C = \frac{1}{4} \sin 2\theta + \frac{1}{24} \sin 12\theta + C \end{aligned}$$

$$\begin{aligned}
 44. \int \frac{\cos x + \sin x}{\sin 2x} dx &= \frac{1}{2} \int \frac{\cos x + \sin x}{\sin x \cos x} dx = \frac{1}{2} \int (\csc x + \sec x) dx \\
 &= \frac{1}{2} \left(\ln |\csc x - \cot x| + \ln |\sec x + \tan x| \right) + C \quad [\text{by Exercise 39 and (1)}]
 \end{aligned}$$

$$45. \int \frac{1 - \tan^2 x}{\sec^2 x} dx = \int (\cos^2 x - \sin^2 x) dx = \int \cos 2x dx = \frac{1}{2} \sin 2x + C$$

$$\begin{aligned}
 46. \int \frac{dx}{\cos x - 1} &= \int \frac{1}{\cos x - 1} \cdot \frac{\cos x + 1}{\cos x + 1} dx = \int \frac{\cos x + 1}{\cos^2 x - 1} dx = \int \frac{\cos x + 1}{-\sin^2 x} dx \\
 &= \int (-\cot x \csc x - \csc^2 x) dx = \csc x + \cot x + C
 \end{aligned}$$

$$\begin{aligned}
 47. \text{Let } u = \tan(t^2) \Rightarrow du &= 2t \sec^2(t^2) dt. \text{ Then} \\
 \int t \sec^2(t^2) \tan^4(t^2) dt &= \int u^4 \left(\frac{1}{2} du\right) = \frac{1}{10} u^5 + C = \frac{1}{10} \tan^5(t^2) + C.
 \end{aligned}$$

$$\begin{aligned}
 48. \text{Let } u = \tan^7 x, dv &= \sec x \tan x dx \Rightarrow du = 7 \tan^6 x \sec^2 x dx, v = \sec x. \text{ Then} \\
 \int \tan^8 x \sec x dx &= \int \tan^7 x \cdot \sec x \tan x dx = \tan^7 x \sec x - \int 7 \tan^6 x \sec^2 x \sec x dx \\
 &= \tan^7 x \sec x - 7 \int \tan^6 x (\tan^2 x + 1) \sec x dx \\
 &= \tan^7 x \sec x - 7 \int \tan^8 x \sec x dx - 7 \int \tan^6 x \sec x dx.
 \end{aligned}$$

Thus, $8 \int \tan^8 x \sec x dx = \tan^7 x \sec x - 7 \int \tan^6 x \sec x dx$ and

$$\int_0^{\pi/4} \tan^8 x \sec x dx = \frac{1}{8} [\tan^7 x \sec x]_0^{\pi/4} - \frac{7}{8} \int_0^{\pi/4} \tan^6 x \sec x dx = \frac{\sqrt{2}}{8} - \frac{7}{8} I.$$

$$\begin{aligned}
 49. \text{Let } u = \cos x \Rightarrow du &= -\sin x dx. \text{ Then} \\
 \int \sin^5 x dx &= \int (1 - \cos^2 x)^2 \sin x dx = \int (1 - u^2)^2 (-du) \\
 &= \int (-1 + 2u^2 - u^4) du = -\frac{1}{5} u^5 + \frac{2}{3} u^3 - u + C \\
 &= -\frac{1}{5} \cos^5 x + \frac{2}{3} \cos^3 x - \cos x + C
 \end{aligned}$$

Notice that F is increasing when $f(x) > 0$, so the graphs serve as a check on our work.

$$\begin{aligned}
 50. \int \sin^4 x \cos^4 x dx &= \int \left(\frac{1}{2} \sin 2x\right)^4 dx = \frac{1}{16} \int \sin^4 2x dx = \frac{1}{16} \int \left[\frac{1}{2} (1 - \cos 4x)\right]^2 dx \\
 &= \frac{1}{64} \int (1 - 2 \cos 4x + \cos^2 4x) dx \\
 &= \frac{1}{64} \left(x - \frac{1}{2} \sin 4x\right) + \frac{1}{128} \int (1 + \cos 8x) dx \\
 &= \frac{1}{64} \left(x - \frac{1}{2} \sin 4x\right) + \frac{1}{128} \left(x + \frac{1}{8} \sin 8x\right) + C \\
 &= \frac{3}{128} x - \frac{1}{128} \sin 4x + \frac{1}{1024} \sin 8x + C
 \end{aligned}$$

Notice that $f(x) = 0$ whenever F has a horizontal tangent.

$$\begin{aligned}
 51. \int \sin 3x \sin 6x dx &= \int \frac{1}{2} [\cos(3x - 6x) - \cos(3x + 6x)] dx \\
 &= \frac{1}{2} \int (\cos 3x - \cos 9x) dx \\
 &= \frac{1}{6} \sin 3x - \frac{1}{18} \sin 9x + C
 \end{aligned}$$

Notice that $f(x) = 0$ whenever F has a horizontal tangent.

58.

It seems from the graph that $\int_0^2 \sin 2\pi x \cos 5\pi x \, dx = 0$, since each bulge above the x -axis seems to have a corresponding depression below the x -axis. To evaluate the integral, we use a trigonometric identity:

$$\begin{aligned} \int_0^1 \sin 2\pi x \cos 5\pi x \, dx &= \frac{1}{2} \int_0^2 [\sin(2\pi x - 5\pi x) + \sin(2\pi x + 5\pi x)] \, dx \\ &= \frac{1}{2} \int_0^2 [\sin(-3\pi x) + \sin 7\pi x] \, dx \\ &= \frac{1}{2} \left[\frac{1}{-3\pi} \cos(-3\pi x) - \frac{1}{7\pi} \cos 7\pi x \right]_0^2 \\ &= \frac{1}{2} \left[\frac{1}{-3\pi} (1 - 1) - \frac{1}{7\pi} (1 - 1) \right] = 0 \end{aligned}$$

$$59. V = \int_{\pi/2}^{\pi} \pi \sin^2 x \, dx = \pi \int_{\pi/2}^{\pi} \frac{1}{2} (1 - \cos 2x) \, dx = \pi \left[\frac{1}{2} x - \frac{1}{4} \sin 2x \right]_{\pi/2}^{\pi} = \pi \left(\frac{\pi}{2} - 0 - \frac{\pi}{4} + 0 \right) = \frac{\pi^2}{4}$$

$$\begin{aligned} 60. \text{Volume} &= \int_0^{\pi/4} \pi (\tan^2 x)^2 \, dx = \pi \int_0^{\pi/4} \tan^2 x (\sec^2 x - 1) \, dx = \pi \int_0^{\pi/4} \tan^2 x \sec^2 x \, dx - \pi \int_0^{\pi/4} \tan^2 x \, dx \\ &= \pi \int_0^{\pi/4} u^2 \, du - \pi \int_0^{\pi/4} (\sec^2 x - 1) \, dx \quad [\text{where } u = \tan x \text{ and } du = \sec^2 x \, dx] \\ &= \pi \left[\frac{1}{3} u^3 \right]_{x=0}^{\pi/4} - \pi [\tan x - x]_0^{\pi/4} = \pi \left[\frac{1}{3} \tan^3 x - \tan x + x \right]_0^{\pi/4} = \pi \left[\frac{1}{3} - 1 + \frac{\pi}{4} \right] = \pi \left(\frac{\pi}{4} - \frac{2}{3} \right) \end{aligned}$$

$$\begin{aligned} 61. \text{Volume} &= \pi \int_0^{\pi/2} [(1 + \cos x)^2 - 1^2] \, dx = \pi \int_0^{\pi/2} (2 \cos x + \cos^2 x) \, dx \\ &= \pi \left[2 \sin x + \frac{1}{2} x + \frac{1}{4} \sin 2x \right]_0^{\pi/2} = \pi \left(2 + \frac{\pi}{4} \right) = 2\pi + \frac{\pi^2}{4} \end{aligned}$$

$$\begin{aligned} 62. \text{Volume} &= \pi \int_0^{\pi/2} [1^2 - (1 - \cos x)^2] \, dx = \pi \int_0^{\pi/2} (2 \cos x - \cos^2 x) \, dx \\ &= \pi \left[2 \sin x - \frac{1}{2} x - \frac{1}{4} \sin 2x \right]_0^{\pi/2} = \pi \left(2 - \frac{\pi}{4} - 0 \right) = 2\pi - \frac{\pi^2}{4} \end{aligned}$$

$$\begin{aligned} 63. s &= f(t) = \int_0^t \sin \omega u \cos^2 \omega u \, du. \text{ Let } y = \cos \omega u \Rightarrow dy = -\omega \sin \omega u \, du. \text{ Then} \\ s &= -\frac{1}{\omega} \int_1^{\cos \omega t} y^2 \, dy = -\frac{1}{\omega} \left[\frac{1}{3} y^3 \right]_1^{\cos \omega t} = \frac{1}{3\omega} (1 - \cos^3 \omega t). \end{aligned}$$

$$\begin{aligned} 64. (a) \text{ We want to calculate the square root of the average value of } [E(t)]^2 &= [155 \sin(120\pi t)]^2 = 155^2 \sin^2(120\pi t). \\ \text{First, we calculate the average value itself, by integrating } [E(t)]^2 &\text{ over one cycle (between } t = 0 \text{ and } t = \frac{1}{60}, \\ \text{since there are 60 cycles per second) and dividing by } &\left(\frac{1}{60} - 0 \right): \end{aligned}$$

$$\begin{aligned} [E(t)]_{\text{ave}}^2 &= \frac{1}{1/60} \int_0^{1/60} [155^2 \sin^2(120\pi t)] \, dt = 60 \cdot 155^2 \int_0^{1/60} \frac{1}{2} [1 - \cos(240\pi t)] \, dt \\ &= 60 \cdot 155^2 \left(\frac{1}{2} \right) \left[t - \frac{1}{240\pi} \sin(240\pi t) \right]_0^{1/60} = 60 \cdot 155^2 \left(\frac{1}{2} \right) \left[\left(\frac{1}{60} - 0 \right) - (0 - 0) \right] = \frac{155^2}{2} \end{aligned}$$

The RMS value is just the square root of this quantity, which is $\frac{155}{\sqrt{2}} \approx 110$ V.

$$(b) 220 = \sqrt{[E(t)]_{\text{ave}}^2} \Rightarrow$$

$$\begin{aligned} 220^2 &= [E(t)]_{\text{ave}}^2 = \frac{1}{1/60} \int_0^{1/60} A^2 \sin^2(120\pi t) \, dt = 60 A^2 \int_0^{1/60} \frac{1}{2} [1 - \cos(240\pi t)] \, dt \\ &= 30 A^2 \left[t - \frac{1}{240\pi} \sin(240\pi t) \right]_0^{1/60} = 30 A^2 \left[\left(\frac{1}{60} - 0 \right) - (0 - 0) \right] = \frac{1}{2} A^2 \end{aligned}$$

$$\text{Thus, } 220^2 = \frac{1}{2} A^2 \Rightarrow A = 220 \sqrt{2} \approx 311 \text{ V.}$$

65. Just note that the integrand is odd [$f(-x) = -f(x)$].

Or: If $m \neq n$, calculate

$$\begin{aligned}\int_{-\pi}^{\pi} \sin mx \cos nx \, dx &= \int_{-\pi}^{\pi} \frac{1}{2} [\sin(m-n)x + \sin(m+n)x] \, dx \\ &= \frac{1}{2} \left[-\frac{\cos(m-n)x}{m-n} - \frac{\cos(m+n)x}{m+n} \right]_{-\pi}^{\pi} = 0\end{aligned}$$

If $m = n$, then the first term in each set of brackets is zero.

66. $\int_{-\pi}^{\pi} \sin mx \sin nx \, dx = \int_{-\pi}^{\pi} \frac{1}{2} [\cos(m-n)x - \cos(m+n)x] \, dx$. If $m \neq n$,

this is equal to $\frac{1}{2} \left[\frac{\sin(m-n)x}{m-n} - \frac{\sin(m+n)x}{m+n} \right]_{-\pi}^{\pi} = 0$. If $m = n$, we get

$$\int_{-\pi}^{\pi} \frac{1}{2} [1 - \cos(m+n)x] \, dx = \left[\frac{1}{2}x \right]_{-\pi}^{\pi} - \left[\frac{\sin(m+n)x}{2(m+n)} \right]_{-\pi}^{\pi} = \pi - 0 = \pi.$$

67. $\int_{-\pi}^{\pi} \cos mx \cos nx \, dx = \int_{-\pi}^{\pi} \frac{1}{2} [\cos(m-n)x + \cos(m+n)x] \, dx$. If $m \neq n$,

this is equal to $\frac{1}{2} \left[\frac{\sin(m-n)x}{m-n} + \frac{\sin(m+n)x}{m+n} \right]_{-\pi}^{\pi} = 0$. If $m = n$, we get

$$\int_{-\pi}^{\pi} \frac{1}{2} [1 + \cos(m+n)x] \, dx = \left[\frac{1}{2}x \right]_{-\pi}^{\pi} + \left[\frac{\sin(m+n)x}{2(m+n)} \right]_{-\pi}^{\pi} = \pi + 0 = \pi.$$

$$68. \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin mx \, dx = \frac{1}{\pi} \int_{-\pi}^{\pi} \left[\left(\sum_{n=1}^m a_n \sin nx \right) \sin mx \right] \, dx = \sum_{n=1}^m \frac{a_n}{\pi} \int_{-\pi}^{\pi} \sin mx \sin nx \, dx.$$

By Exercise 66, every term is zero except the m th one, and that term is $\frac{a_m}{\pi} \cdot \pi = a_m$.

8.3 Trigonometric Substitution

1. Let $x = 3 \sec \theta$, where $0 \leq \theta < \frac{\pi}{2}$ or $\pi \leq \theta < \frac{3\pi}{2}$. Then

$$dx = 3 \sec \theta \tan \theta \, d\theta \text{ and}$$

$$\begin{aligned}\sqrt{x^2 - 9} &= \sqrt{9 \sec^2 \theta - 9} = \sqrt{9(\sec^2 \theta - 1)} = \sqrt{9 \tan^2 \theta} \\ &= 3 |\tan \theta| = 3 \tan \theta \text{ for the relevant values of } \theta.\end{aligned}$$

$$\int \frac{1}{x^2 \sqrt{x^2 - 9}} \, dx = \int \frac{1}{9 \sec^2 \theta \cdot 3 \tan \theta} 3 \sec \theta \tan \theta \, d\theta = \frac{1}{9} \int \cos \theta \, d\theta = \frac{1}{9} \sin \theta + C = \frac{1}{9} \frac{\sqrt{x^2 - 9}}{x} + C$$

Note that $-\sec(\theta + \pi) = \sec \theta$, so the figure is sufficient for the case $\pi \leq \theta < \frac{3\pi}{2}$.

2. Let $x = 3 \sin \theta$, where $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Then $dx = 3 \cos \theta d\theta$ and

$$\begin{aligned}\sqrt{9-x^2} &= \sqrt{9-9\sin^2\theta} = \sqrt{9(1-\sin^2\theta)} = \sqrt{9\cos^2\theta} \\ &= 3|\cos\theta| = 3\cos\theta \text{ for the relevant values of } \theta.\end{aligned}$$

$$\begin{aligned}\int x^3 \sqrt{9-x^2} dx &= \int 3^3 \sin^3 \theta \cdot 3 \cos \theta \cdot 3 \cos \theta d\theta = 3^5 \int \sin^3 \theta \cos^2 \theta d\theta \\ &= 3^5 \int \sin^2 \theta \cos^2 \theta \sin \theta d\theta = 3^5 \int (1-\cos^2 \theta) \cos^2 \theta \sin \theta d\theta \\ &= 3^5 \int (1-u^2) u^2 (-du) \quad [u = \cos \theta, du = -\sin \theta d\theta] \\ &= 3^5 \int (u^4 - u^2) du = 3^5 \left(\frac{1}{5} u^5 - \frac{1}{3} u^3 \right) + C = 3^5 \left(\frac{1}{5} \cos^5 \theta - \frac{1}{3} \cos^3 \theta \right) + C \\ &= 3^5 \left[\frac{1}{5} \frac{(9-x^2)^{5/2}}{3^5} - \frac{1}{3} \frac{(9-x^2)^{3/2}}{3^3} \right] + C \\ &= \frac{1}{5} (9-x^2)^{5/2} - 3(9-x^2)^{3/2} + C \text{ or } -\frac{1}{5} (x^2+6)(9-x)^{3/2} + C\end{aligned}$$

3. Let $x = 3 \tan \theta$, where $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$. Then $dx = 3 \sec^2 \theta d\theta$ and

$$\begin{aligned}\sqrt{x^2+9} &= \sqrt{9\tan^2\theta+9} = \sqrt{9(\tan^2\theta+1)} = \sqrt{9\sec^2\theta} \\ &= 3|\sec\theta| = 3\sec\theta \text{ for the relevant values of } \theta.\end{aligned}$$

$$\begin{aligned}\int \frac{x^3}{\sqrt{x^2+9}} dx &= \int \frac{3^3 \tan^3 \theta}{3 \sec \theta} 3 \sec^2 \theta d\theta = 3^3 \int \tan^3 \theta \sec \theta d\theta = 3^3 \int \tan^2 \theta \tan \theta \sec \theta d\theta \\ &= 3^3 \int (\sec^2 \theta - 1) \tan \theta \sec \theta d\theta = 3^3 \int (u^2 - 1) du \quad [u = \sec \theta, du = \sec \theta \tan \theta d\theta] \\ &= 3^3 \left(\frac{1}{3} u^3 - u \right) + C = 3^3 \left(\frac{1}{3} \sec^3 \theta - \sec \theta \right) + C = 3^3 \left[\frac{1}{3} \frac{(x^2+9)^{3/2}}{3^3} - \frac{\sqrt{x^2+9}}{3} \right] + C \\ &= \frac{1}{3} (x^2+9)^{3/2} - 9\sqrt{x^2+9} + C \text{ or } \frac{1}{3} (x^2-18)\sqrt{x^2+9} + C\end{aligned}$$

4. Let $x = 4 \sin \theta$, where $-\pi/2 \leq \theta \leq \pi/2$. Then $dx = 4 \cos \theta d\theta$ and

$$\sqrt{16-x^2} = \sqrt{16-16\sin^2\theta} = \sqrt{16\cos^2\theta} = 4|\cos\theta| = 4\cos\theta. \text{ When } x=0, 4\sin\theta=0 \Rightarrow \theta=0, \text{ and}$$

$$\text{when } x=2\sqrt{3}, 4\sin\theta=2\sqrt{3} \Rightarrow \sin\theta=\frac{\sqrt{3}}{2} \Rightarrow \theta=\frac{\pi}{3}. \text{ Thus, substitution gives}$$

$$\begin{aligned}\int_0^{2\sqrt{3}} \frac{x^3}{\sqrt{16-x^2}} dx &= \int_0^{\pi/3} \frac{4^3 \sin^3 \theta}{4 \cos \theta} 4 \cos \theta d\theta = 4^3 \int_0^{\pi/3} \sin^3 \theta d\theta \\ &= 4^3 \int_0^{\pi/3} (1-\cos^2 \theta) \sin \theta d\theta \\ &\stackrel{c}{=} -4^3 \int_1^{1/2} (1-u^2) du = -64 \left[u - \frac{1}{3} u^3 \right]_1^{1/2} \\ &= -64 \left[\left(\frac{1}{2} - \frac{1}{24} \right) - \left(1 - \frac{1}{3} \right) \right] = -64 \left(-\frac{5}{24} \right) = \frac{40}{3}\end{aligned}$$

Or: Let $u = 16 - x^2$, $x^2 = 16 - u$, $du = -2x dx$.

5. Let $t = \sec \theta$, so $dt = \sec \theta \tan \theta d\theta$, $t = \sqrt{2} \Rightarrow \theta = \frac{\pi}{4}$, and $t = 2 \Rightarrow \theta = \frac{\pi}{3}$. Then

$$\begin{aligned} \int_{\sqrt{2}}^2 \frac{1}{t^3 \sqrt{t^2 - 1}} dt &= \int_{\pi/4}^{\pi/3} \frac{1}{\sec^3 \theta \tan \theta} \sec \theta \tan \theta d\theta = \int_{\pi/4}^{\pi/3} \frac{1}{\sec^2 \theta} d\theta = \int_{\pi/4}^{\pi/3} \cos^2 \theta d\theta \\ &= \int_{\pi/4}^{\pi/3} \frac{1}{2} (1 + \cos 2\theta) d\theta = \frac{1}{2} \left[\theta + \frac{1}{2} \sin 2\theta \right]_{\pi/4}^{\pi/3} \\ &= \frac{1}{2} \left[\left(\frac{\pi}{3} + \frac{1}{2} \frac{\sqrt{3}}{2} \right) - \left(\frac{\pi}{4} + \frac{1}{2} \cdot 1 \right) \right] = \frac{1}{2} \left(\frac{\pi}{12} + \frac{\sqrt{3}}{4} - \frac{1}{2} \right) = \frac{\pi}{24} + \frac{\sqrt{3}}{8} - \frac{1}{4} \end{aligned}$$

6. Let $x = 2 \tan \theta$, so $dx = 2 \sec^2 \theta d\theta$, $x = 0 \Rightarrow \theta = 0$, and $x = 2 \Rightarrow \theta = \frac{\pi}{4}$. Then

$$\begin{aligned} \int_0^2 x^3 \sqrt{x^2 + 4} dx &= \int_0^{\pi/4} 2^3 \tan^3 \theta \cdot 2 \sec \theta \cdot 2 \sec^2 \theta d\theta = 2^5 \int_0^{\pi/4} \tan^2 \theta \sec^2 \theta \sec \theta \tan \theta d\theta \\ &= 2^5 \int_0^{\pi/4} (\sec^2 \theta - 1) \sec^2 \theta \sec \theta \tan \theta d\theta \\ &= 2^5 \int_1^{\sqrt{2}} (u^2 - 1) u^2 du \quad [u = \sec \theta, du = \sec \theta \tan \theta d\theta] \\ &= 2^5 \int_1^{\sqrt{2}} (u^4 - u^2) du = 2^5 \left[\frac{1}{5} u^5 - \frac{1}{3} u^3 \right]_1^{\sqrt{2}} = 2^5 \left[\left(\frac{1}{5} \cdot 4\sqrt{2} - \frac{1}{3} \cdot 2\sqrt{2} \right) - \left(\frac{1}{5} - \frac{1}{3} \right) \right] \\ &= 32 \left(\frac{2}{15} \sqrt{2} + \frac{2}{15} \right) = \frac{64}{15} (\sqrt{2} + 1) \end{aligned}$$

Or: Let $u = x^2 + 4$, $x^2 = u - 4$, $du = 2x dx$.

7. Let $x = 5 \sin \theta$, so $dx = 5 \cos \theta d\theta$. Then

$$\begin{aligned} \int \frac{1}{x^2 \sqrt{25 - x^2}} dx &= \int \frac{1}{5^2 \sin^2 \theta \cdot 5 \cos \theta} 5 \cos \theta d\theta \\ &= \frac{1}{25} \int \csc^2 \theta d\theta = -\frac{1}{25} \cot \theta + C \\ &= -\frac{1}{25} \frac{\sqrt{25 - x^2}}{x} + C \end{aligned}$$

8. Let $x = a \sec \theta$, where $0 \leq \theta < \frac{\pi}{2}$ or $\pi \leq \theta < \frac{3\pi}{2}$. Then

$dx = a \sec \theta \tan \theta d\theta$ and $\sqrt{x^2 - a^2} = a \tan \theta$, so

$$\begin{aligned} \int \frac{\sqrt{x^2 - a^2}}{x^4} dx &= \int \frac{a \tan \theta}{a^4 \sec^4 \theta} a \sec \theta \tan \theta d\theta \\ &= \frac{1}{a^2} \int \sin^2 \theta \cos \theta d\theta \\ &= \frac{1}{3a^2} \sin^3 \theta + C = \frac{(x^2 - a^2)^{3/2}}{3a^2 x^3} + C \end{aligned}$$

9. Let $x = 4 \tan \theta$, where $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$. Then $dx = 4 \sec^2 \theta d\theta$ and

$$\begin{aligned}\sqrt{x^2 + 16} &= \sqrt{16 \tan^2 \theta + 16} = \sqrt{16(\tan^2 \theta + 1)} \\ &= \sqrt{16 \sec^2 \theta} = 4 |\sec \theta| \\ &= 4 \sec \theta \text{ for the relevant values of } \theta.\end{aligned}$$

$$\begin{aligned}\int \frac{dx}{\sqrt{x^2 + 16}} &= \int \frac{4 \sec^2 \theta d\theta}{4 \sec \theta} = \int \sec \theta d\theta = \ln |\sec \theta + \tan \theta| + C_1 \\ &= \ln \left| \frac{\sqrt{x^2 + 16}}{4} + \frac{x}{4} \right| + C_1 = \ln |\sqrt{x^2 + 16} + x| - \ln |4| + C_1 \\ &= \ln(\sqrt{x^2 + 16} + x) + C, \text{ where } C = C_1 - \ln 4.\end{aligned}$$

(Since $\sqrt{x^2 + 16} + x > 0$, we don't need the absolute value.)

10. Let $t = \sqrt{2} \tan \theta$, where $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$. Then $dt = \sqrt{2} \sec^2 \theta d\theta$ and

$$\begin{aligned}\sqrt{t^2 + 2} &= \sqrt{2 \tan^2 \theta + 2} = \sqrt{2(\tan^2 \theta + 1)} = \sqrt{2 \sec^2 \theta} \\ &= \sqrt{2} |\sec \theta| = \sqrt{2} \sec \theta \text{ for the relevant values of } \theta.\end{aligned}$$

$$\begin{aligned}\int \frac{t^5}{\sqrt{t^2 + 2}} dt &= \int \frac{4 \sqrt{2} \tan^5 \theta}{\sqrt{2} \sec \theta} \sqrt{2} \sec^2 \theta d\theta = 4 \sqrt{2} \int \tan^5 \theta \sec \theta d\theta = 4 \sqrt{2} \int (\sec^2 \theta - 1)^2 \sec \theta \tan \theta d\theta \\ &= 4 \sqrt{2} \int (u^2 - 1)^2 du \quad [u = \sec \theta, du = \sec \theta \tan \theta d\theta] = 4 \sqrt{2} \int (u^4 - 2u^2 + 1) du \\ &= 4 \sqrt{2} \left(\frac{1}{5} u^5 - \frac{2}{3} u^3 + u \right) + C = \frac{4 \sqrt{2}}{15} u(3u^4 - 10u^2 + 15) + C \\ &= \frac{4 \sqrt{2}}{15} \cdot \frac{\sqrt{t^2 + 2}}{\sqrt{2}} \left[3 \cdot \frac{(t^2 + 2)^2}{2^2} - 10 \frac{t^2 + 2}{2} + 15 \right] + C \\ &= \frac{4}{15} \sqrt{t^2 + 2} \cdot \frac{1}{4} [3(t^4 + 4t^2 + 4) - 20(t^2 + 2) + 60] + C \\ &= \frac{1}{15} \sqrt{t^2 + 2} (3t^4 - 8t^2 + 32) + C\end{aligned}$$

11. Let $2x = \sin \theta$, where $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Then $x = \frac{1}{2} \sin \theta$,

$$dx = \frac{1}{2} \cos \theta d\theta, \text{ and } \sqrt{1 - 4x^2} = \sqrt{1 - (\sin \theta)^2} = \cos \theta.$$

$$\begin{aligned}\int \sqrt{1 - 4x^2} dx &= \int \cos \theta \left(\frac{1}{2} \cos \theta \right) d\theta = \frac{1}{4} \int (1 + \cos 2\theta) d\theta \\ &= \frac{1}{4} \left(\theta + \frac{1}{2} \sin 2\theta \right) + C = \frac{1}{4} (\theta + \sin \theta \cos \theta) + C \\ &= \frac{1}{4} \left[\sin^{-1}(2x) + 2x \sqrt{1 - 4x^2} \right] + C\end{aligned}$$

12. $\int_0^1 x \sqrt{x^2 + 4} dx = \int_4^5 \sqrt{u} \left(\frac{1}{2} du \right) \quad [u = x^2 + 4, du = 2x dx] = \frac{1}{2} \cdot \frac{2}{3} \left[u^{3/2} \right]_4^5 = \frac{1}{3} (5\sqrt{5} - 8)$

13. Let $x = 3 \sec \theta$, where $0 \leq \theta < \frac{\pi}{2}$ or $\pi \leq \theta < \frac{3\pi}{2}$. Then

$$dx = 3 \sec \theta \tan \theta d\theta \text{ and } \sqrt{x^2 - 9} = 3 \tan \theta, \text{ so}$$

$$\int \frac{\sqrt{x^2 - 9}}{x^3} dx = \int \frac{3 \tan \theta}{27 \sec^3 \theta} 3 \sec \theta \tan \theta d\theta = \frac{1}{3} \int \frac{\tan^2 \theta}{\sec^2 \theta} d\theta$$

$$= \frac{1}{3} \int \sin^2 \theta d\theta = \frac{1}{3} \int \frac{1}{2} (1 - \cos 2\theta) d\theta = \frac{1}{6} \theta - \frac{1}{12} \sin 2\theta + C = \frac{1}{6} \theta - \frac{1}{6} \sin \theta \cos \theta + C$$

$$= \frac{1}{6} \sec^{-1} \left(\frac{x}{3} \right) - \frac{1}{6} \frac{\sqrt{x^2 - 9}}{x} \frac{3}{x} + C = \frac{1}{6} \sec^{-1} \left(\frac{x}{3} \right) - \frac{\sqrt{x^2 - 9}}{2x^2} + C$$

14. Let $u = \sqrt{5} \sin \theta$, so $du = \sqrt{5} \cos \theta d\theta$. Then

$$\int \frac{du}{u \sqrt{5 - u^2}} = \int \frac{1}{\sqrt{5} \sin \theta \cdot \sqrt{5} \cos \theta} \sqrt{5} \cos \theta d\theta = \frac{1}{\sqrt{5}} \int \csc \theta d\theta$$

$$= \frac{1}{\sqrt{5}} \ln |\csc \theta - \cot \theta| + C \quad [\text{by Exercise 8.2.39}]$$

$$= \frac{1}{\sqrt{5}} \ln \left| \frac{\sqrt{5}}{u} - \frac{\sqrt{5 - u^2}}{u} \right| + C$$

$$= \frac{1}{\sqrt{5}} \ln \left| \frac{\sqrt{5} - \sqrt{5 - u^2}}{u} \right| + C$$

15. Let $x = a \sin \theta$, where $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Then $dx = a \cos \theta d\theta$ and

$$\int \frac{x^2 dx}{(a^2 - x^2)^{3/2}} = \int \frac{a^2 \sin^2 \theta a \cos \theta d\theta}{a^3 \cos^3 \theta} = \int \tan^2 \theta d\theta$$

$$= \int (\sec^2 \theta - 1) d\theta = \tan \theta - \theta + C$$

$$= \frac{x}{\sqrt{a^2 - x^2}} - \sin^{-1} \frac{x}{a} + C$$

16. Let $4x = 3 \sec \theta$, where $0 \leq \theta < \frac{\pi}{2}$ or $\pi \leq \theta < \frac{3\pi}{2}$. Then

$$dx = \frac{3}{4} \sec \theta \tan \theta d\theta \text{ and } \sqrt{16x^2 - 9} = 3 \tan \theta, \text{ so}$$

$$\int \frac{dx}{x^2 \sqrt{16x^2 - 9}} = \int \frac{\frac{3}{4} \sec \theta \tan \theta d\theta}{\left(\frac{3}{4}\right)^2 \sec^2 \theta 3 \tan \theta}$$

$$= \frac{4}{9} \int \cos \theta d\theta = \frac{4}{9} \sin \theta + C = \frac{4}{9} \frac{\sqrt{16x^2 - 9}}{4x} + C = \frac{\sqrt{16x^2 - 9}}{9x} + C$$

17. Let $u = x^2 - 7$, so $du = 2x dx$. Then $\int \frac{x}{\sqrt{x^2 - 7}} dx = \frac{1}{2} \int \frac{1}{\sqrt{u}} du = \frac{1}{2} \cdot 2 \sqrt{u} + C = \sqrt{x^2 - 7} + C$.

18. Let
- $ax = b \sec \theta$
- , so
- $(ax)^2 = b^2 \sec^2 \theta \Rightarrow$

$$(ax)^2 - b^2 = b^2 \sec^2 \theta - b^2 = b^2 (\sec^2 \theta - 1) = b^2 \tan^2 \theta. \text{ So}$$

$$\sqrt{(ax)^2 - b^2} = b \tan \theta, dx = \frac{b}{a} \sec \theta \tan \theta d\theta, \text{ and}$$

$$\begin{aligned} \int \frac{dx}{[(ax)^2 - b^2]^{3/2}} &= \int \frac{\frac{b}{a} \sec \theta \tan \theta}{b^3 \tan^3 \theta} d\theta = \frac{1}{ab^2} \int \frac{\sec \theta}{\tan^2 \theta} d\theta = \frac{1}{ab^2} \int \frac{\cos \theta}{\sin^2 \theta} d\theta = \frac{1}{ab^2} \int \csc \theta \cot \theta d\theta \\ &= -\frac{1}{ab^2} \csc \theta + C = -\frac{1}{ab^2} \frac{ax}{\sqrt{(ax)^2 - b^2}} + C = -\frac{x}{b^2 \sqrt{(ax)^2 - b^2}} + C \end{aligned}$$

19. Let
- $x = \tan \theta$
- , where
- $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$
- . Then
- $dx = \sec^2 \theta d\theta$

$$\text{and } \sqrt{1+x^2} = \sec \theta, \text{ so}$$

$$\begin{aligned} \int \frac{\sqrt{1+x^2}}{x} dx &= \int \frac{\sec \theta}{\tan \theta} \sec^2 \theta d\theta = \int \frac{\sec \theta}{\tan \theta} (1 + \tan^2 \theta) d\theta \\ &= \int (\csc \theta + \sec \theta \tan \theta) d\theta \\ &= \ln |\csc \theta - \cot \theta| + \sec \theta + C \quad [\text{by Exercise 8.2.39}] \\ &= \ln \left| \frac{\sqrt{1+x^2}}{x} - \frac{1}{x} \right| + \frac{\sqrt{1+x^2}}{1} + C = \ln \left| \frac{\sqrt{1+x^2} - 1}{x} \right| + \sqrt{1+x^2} + C \end{aligned}$$

20. Let
- $t = 5 \sin \theta$
- , where
- $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$
- . Then
- $dt = 5 \cos \theta d\theta$

$$\text{and } \sqrt{25-t^2} = 5 \cos \theta, \text{ so}$$

$$\begin{aligned} \int \frac{t}{\sqrt{25-t^2}} dt &= \int \frac{5 \sin \theta}{5 \cos \theta} 5 \cos \theta d\theta = 5 \int \sin \theta d\theta \\ &= -5 \cos \theta + C = -5 \cdot \frac{\sqrt{25-t^2}}{5} + C = -\sqrt{25-t^2} + C \end{aligned}$$

$$\text{Or: Let } u = 25 - t^2, \text{ so } du = -2t dt.$$

21. Let
- $u = 4 - 9x^2 \Rightarrow du = -18x dx$
- . Then
- $x^2 = \frac{1}{9}(4-u)$
- and

$$\begin{aligned} \int_0^{2/3} x^3 \sqrt{4-9x^2} dx &= \int_4^0 \frac{1}{9}(4-u) u^{1/2} \left(-\frac{1}{18}\right) du = \frac{1}{162} \int_0^4 (4u^{1/2} - u^{3/2}) du \\ &= \frac{1}{162} \left[\frac{8}{3} u^{3/2} - \frac{2}{5} u^{5/2} \right]_0^4 = \frac{1}{162} \left[\frac{64}{3} - \frac{64}{5} \right] = \frac{64}{1215} \end{aligned}$$

$$\text{Or: Let } 3x = 2 \sin \theta, \text{ where } -\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}.$$

22. Let
- $x = \tan \theta$
- , where
- $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$
- . Then
- $dx = \sec^2 \theta d\theta$
- ,

$$\sqrt{x^2+1} = \sec \theta \text{ and } x=0 \Rightarrow \theta=0, x=1 \Rightarrow \theta=\frac{\pi}{4}, \text{ so}$$

$$\begin{aligned} \int_0^1 \sqrt{x^2+1} dx &= \int_0^{\pi/4} \sec \theta \sec^2 \theta d\theta = \int_0^{\pi/4} \sec^3 \theta d\theta \\ &= \frac{1}{2} \left[\sec \theta \tan \theta + \ln |\sec \theta + \tan \theta| \right]_0^{\pi/4} \quad [\text{by Example 8.2.8}] \\ &= \frac{1}{2} \left[\sqrt{2} \cdot 1 + \ln(1 + \sqrt{2}) - 0 - \ln(1+0) \right] = \frac{1}{2} \left[\sqrt{2} + \ln(1 + \sqrt{2}) \right] \end{aligned}$$

23. $5 + 4x - x^2 = -(x^2 - 4x + 4) + 9 = -(x - 2)^2 + 9$. Let

$x - 2 = 3 \sin \theta$, $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$, so $dx = 3 \cos \theta d\theta$. Then

$$\begin{aligned} \int \sqrt{5 + 4x - x^2} dx &= \int \sqrt{9 - (x - 2)^2} dx = \int \sqrt{9 - 9 \sin^2 \theta} 3 \cos \theta d\theta \\ &= \int \sqrt{9 \cos^2 \theta} 3 \cos \theta d\theta = \int 9 \cos^2 \theta d\theta \\ &= \frac{9}{2} \int (1 + \cos 2\theta) d\theta = \frac{9}{2} \left(\theta + \frac{1}{2} \sin 2\theta \right) + C \\ &= \frac{9}{2} \theta + \frac{9}{4} \sin 2\theta + C = \frac{9}{2} \theta + \frac{9}{4} (2 \sin \theta \cos \theta) + C \\ &= \frac{9}{2} \sin^{-1} \left(\frac{x-2}{3} \right) + \frac{9}{2} \cdot \frac{x-2}{3} \cdot \frac{\sqrt{5+4x-x^2}}{3} + C \\ &= \frac{9}{2} \sin^{-1} \left(\frac{x-2}{3} \right) + \frac{1}{2} (x-2) \sqrt{5+4x-x^2} + C \end{aligned}$$

24. $t^2 - 6t + 13 = (t^2 - 6t + 9) + 4 = (t - 3)^2 + 2^2$. Let $t - 3 = 2 \tan \theta$,

so $dt = 2 \sec^2 \theta d\theta$. Then

$$\begin{aligned} \int \frac{dt}{\sqrt{t^2 - 6t + 13}} &= \int \frac{1}{\sqrt{(2 \tan \theta)^2 + 2^2}} 2 \sec^2 \theta d\theta = \int \frac{2 \sec^2 \theta}{2 \sec \theta} d\theta \\ &= \int \sec \theta d\theta = \ln |\sec \theta + \tan \theta| + C_1 \quad [\text{by Formula 8.2.1}] \\ &= \ln \left| \frac{\sqrt{t^2 - 6t + 13}}{2} + \frac{t-3}{2} \right| + C_1 \\ &= \ln |\sqrt{t^2 - 6t + 13} + t - 3| + C \quad \text{where } C = C_1 - \ln 2 \end{aligned}$$

25. $9x^2 + 6x - 8 = (3x + 1)^2 - 9$, so let $u = 3x + 1$, $du = 3dx$. Then $\int \frac{dx}{\sqrt{9x^2 + 6x - 8}} = \int \frac{\frac{1}{3} du}{\sqrt{u^2 - 9}}$. Now let $u = 3 \sec \theta$, where $0 \leq \theta < \frac{\pi}{2}$ or $\pi \leq \theta < \frac{3\pi}{2}$. Then $du = 3 \sec \theta \tan \theta d\theta$ and $\sqrt{u^2 - 9} = 3 \tan \theta$, so

$$\begin{aligned} \int \frac{\frac{1}{3} du}{\sqrt{u^2 - 9}} &= \int \frac{\sec \theta \tan \theta d\theta}{3 \tan \theta} = \frac{1}{3} \int \sec \theta d\theta = \frac{1}{3} \ln |\sec \theta + \tan \theta| + C_1 = \frac{1}{3} \ln \left| \frac{u + \sqrt{u^2 - 9}}{3} \right| + C_1 \\ &= \frac{1}{3} \ln |u + \sqrt{u^2 - 9}| + C = \frac{1}{3} \ln |3x + 1 + \sqrt{9x^2 + 6x - 8}| + C \end{aligned}$$

26. $4x - x^2 = -(x^2 - 4x + 4) + 4 = 4 - (x - 2)^2$, so let $u = x - 2$. Then $x = u + 2$ and $dx = du$, so

$$\begin{aligned} \int \frac{x^2 dx}{\sqrt{4x - x^2}} &= \int \frac{(u + 2)^2 du}{\sqrt{4 - u^2}} = \int \frac{(2 \sin \theta + 2)^2}{2 \cos \theta} 2 \cos \theta d\theta \quad [\text{Put } u = 2 \sin \theta] \\ &= 4 \int (\sin^2 \theta + 2 \sin \theta + 1) d\theta \\ &= 2 \int (1 - \cos 2\theta) d\theta + 8 \int \sin \theta d\theta + 4 \int d\theta \\ &= 2\theta - \sin 2\theta - 8 \cos \theta + 4\theta + C \\ &= 6\theta - 8 \cos \theta - 2 \sin \theta \cos \theta + C \\ &= 6 \sin^{-1} \left(\frac{1}{2} u \right) - 4 \sqrt{4 - u^2} - \frac{1}{2} u \sqrt{4 - u^2} + C \\ &= 6 \sin^{-1} \left(\frac{x-2}{2} \right) - 4 \sqrt{4x - x^2} - \left(\frac{x-2}{2} \right) \sqrt{4x - x^2} + C \end{aligned}$$

27. $x^2 + 2x + 2 = (x + 1)^2 + 1$. Let $u = x + 1$, $du = dx$. Then

$$\begin{aligned}\int \frac{dx}{(x^2 + 2x + 2)^2} &= \int \frac{du}{(u^2 + 1)^2} = \int \frac{\sec^2 \theta d\theta}{\sec^4 \theta} \quad \left[\begin{array}{l} \text{where } u = \tan \theta, du = \sec^2 \theta d\theta, \\ \text{and } u^2 + 1 = \sec^2 \theta \end{array} \right] \\ &= \int \cos^2 \theta d\theta = \frac{1}{2} \int (1 + \cos 2\theta) d\theta = \frac{1}{2}(\theta + \sin \theta \cos \theta) + C \\ &= \frac{1}{2} \left[\tan^{-1} u + \frac{u}{1 + u^2} \right] + C = \frac{1}{2} \left[\tan^{-1}(x + 1) + \frac{x + 1}{x^2 + 2x + 2} \right] + C\end{aligned}$$

28. $5 - 4x - x^2 = -(x^2 + 4x + 4) + 9 = 9 - (x + 2)^2$. Let $u = x + 2 \Rightarrow du = dx$. Then

$$\begin{aligned}\int \frac{dx}{(5 - 4x - x^2)^{5/2}} &= \int \frac{du}{(9 - u^2)^{5/2}} = \int \frac{3 \cos \theta d\theta}{(3 \cos \theta)^5} \quad \left[\begin{array}{l} \text{where } u = 3 \sin \theta, du = 3 \cos \theta d\theta, \\ \text{and } \sqrt{9 - u^2} = 3 \cos \theta \end{array} \right] \\ &= \frac{1}{81} \int \sec^4 \theta d\theta = \frac{1}{81} \int (\tan^2 \theta + 1) \sec^2 \theta d\theta = \frac{1}{81} \left[\frac{1}{3} \tan^3 \theta + \tan \theta \right] + C \\ &= \frac{1}{243} \left[\frac{u^3}{(9 - u^2)^{3/2}} + \frac{3u}{\sqrt{9 - u^2}} \right] + C = \frac{1}{243} \left[\frac{(x + 2)^3}{(5 - 4x - x^2)^{3/2}} + \frac{3(x + 2)}{\sqrt{5 - 4x - x^2}} \right] + C\end{aligned}$$

29. Let $u = x^2$, $du = 2x dx$. Then

$$\begin{aligned}\int x \sqrt{1 - x^4} dx &= \int \sqrt{1 - u^2} \left(\frac{1}{2} du \right) = \frac{1}{2} \int \cos \theta \cdot \cos \theta d\theta \quad \left[\begin{array}{l} \text{where } u = \sin \theta, du = \cos \theta d\theta, \\ \text{and } \sqrt{1 - u^2} = \cos \theta \end{array} \right] \\ &= \frac{1}{2} \int \frac{1}{2} (1 + \cos 2\theta) d\theta = \frac{1}{4} \theta + \frac{1}{8} \sin 2\theta + C = \frac{1}{4} \theta + \frac{1}{4} \sin \theta \cos \theta + C \\ &= \frac{1}{4} \sin^{-1} u + \frac{1}{4} u \sqrt{1 - u^2} + C = \frac{1}{4} \sin^{-1}(x^2) + \frac{1}{4} x^2 \sqrt{1 - x^4} + C\end{aligned}$$

30. Let $u = \sin t$, $du = \cos t dt$. Then

$$\begin{aligned}\int_0^{\pi/2} \frac{\cos t}{\sqrt{1 + \sin^2 t}} dt &= \int_0^1 \frac{1}{\sqrt{1 + u^2}} du = \int_0^{\pi/4} \frac{1}{\sec \theta} \sec^2 \theta d\theta \quad \left[\begin{array}{l} \text{where } u = \tan \theta, du = \sec^2 \theta d\theta, \\ \text{and } \sqrt{1 + u^2} = \sec \theta \end{array} \right] \\ &= \int_0^{\pi/4} \sec \theta d\theta = \left[\ln |\sec \theta + \tan \theta| \right]_0^{\pi/4} \quad [\text{by (1) in Section 8.2}] \\ &= \ln(\sqrt{2} + 1) - \ln(1 + 0) = \ln(\sqrt{2} + 1)\end{aligned}$$

31. (a) Let $x = a \tan \theta$, where $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$. Then $\sqrt{x^2 + a^2} = a \sec \theta$ and

$$\begin{aligned}\int \frac{dx}{\sqrt{x^2 + a^2}} &= \int \frac{a \sec^2 \theta d\theta}{a \sec \theta} = \int \sec \theta d\theta = \ln |\sec \theta + \tan \theta| + C_1 = \ln \left| \frac{\sqrt{x^2 + a^2}}{a} + \frac{x}{a} \right| + C_1 \\ &= \ln \left(x + \sqrt{x^2 + a^2} \right) + C \quad \text{where } C = C_1 - \ln |a|\end{aligned}$$

(b) Let $x = a \sinh t$, so that $dx = a \cosh t dt$ and $\sqrt{x^2 + a^2} = a \cosh t$. Then

$$\int \frac{dx}{\sqrt{x^2 + a^2}} = \int \frac{a \cosh t dt}{a \cosh t} = t + C = \sinh^{-1} \frac{x}{a} + C.$$

32. (a) Let $x = a \tan \theta$, $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$. Then

$$\begin{aligned}I &= \int \frac{x^2}{(x^2 + a^2)^{3/2}} dx = \int \frac{a^2 \tan^2 \theta}{a^3 \sec^3 \theta} a \sec^2 \theta d\theta = \int \frac{\tan^2 \theta}{\sec \theta} d\theta = \int \frac{\sec^2 \theta - 1}{\sec \theta} d\theta \\ &= \int (\sec \theta - \cos \theta) d\theta = \ln |\sec \theta + \tan \theta| - \sin \theta + C \\ &= \ln \left| \frac{\sqrt{x^2 + a^2}}{a} + \frac{x}{a} \right| - \frac{x}{\sqrt{x^2 + a^2}} + C = \ln \left(x + \sqrt{x^2 + a^2} \right) - \frac{x}{\sqrt{x^2 + a^2}} + C_1\end{aligned}$$

(b) Let $x = a \sinh t$. Then

$$\begin{aligned} I &= \int \frac{a^2 \sinh^2 t}{a^3 \cosh^3 t} a \cosh t dt = \int \tanh^2 t dt = \int (1 - \operatorname{sech}^2 t) dt = t - \tanh t + C \\ &= \sinh^{-1} \frac{x}{a} - \frac{x}{\sqrt{a^2 + x^2}} + C \end{aligned}$$

33. The average value of $f(x) = \sqrt{x^2 - 1}/x$ on the interval $[1, 7]$ is

$$\begin{aligned} \frac{1}{7-1} \int_1^7 \frac{\sqrt{x^2 - 1}}{x} dx &= \frac{1}{6} \int_0^\alpha \frac{\tan \theta}{\sec \theta} \cdot \sec \theta \tan \theta d\theta \quad \left[\begin{array}{l} \text{where } x = \sec \theta, dx = \sec \theta \tan \theta d\theta, \\ \sqrt{x^2 - 1} = \tan \theta, \text{ and } \alpha = \sec^{-1} 7 \end{array} \right] \\ &= \frac{1}{6} \int_0^\alpha \tan^2 \theta d\theta = \frac{1}{6} \int_0^\alpha (\sec^2 \theta - 1) d\theta \\ &= \frac{1}{6} [\tan \theta - \theta]_0^\alpha = \frac{1}{6} (\tan \alpha - \alpha) \\ &= \frac{1}{6} (\sqrt{48} - \sec^{-1} 7) \end{aligned}$$

34. $9x^2 - 4y^2 = 36 \Rightarrow y = \pm \frac{3}{2} \sqrt{x^2 - 4} \Rightarrow$

$$\text{area} = 2 \int_2^3 \frac{3}{2} \sqrt{x^2 - 4} dx = 3 \int_2^3 \sqrt{x^2 - 4} dx$$

$$\begin{aligned} &= 3 \int_0^\alpha 2 \tan \theta \sec \theta \tan \theta d\theta \quad \left[\begin{array}{l} \text{where } x = 2 \sec \theta, \\ dx = 2 \sec \theta \tan \theta d\theta, \\ \alpha = \sec^{-1} \frac{3}{2} \end{array} \right] \\ &= 12 \int_0^\alpha (\sec^2 \theta - 1) \sec \theta d\theta = 12 \int_0^\alpha (\sec^3 \theta - \sec \theta) d\theta \\ &= 12 \left[\frac{1}{2} (\sec \theta \tan \theta + \ln |\sec \theta + \tan \theta|) - \ln |\sec \theta + \tan \theta| \right]_0^\alpha \\ &= 6 \left[\sec \theta \tan \theta - \ln |\sec \theta + \tan \theta| \right]_0^\alpha \\ &= 6 \left[\frac{3\sqrt{5}}{4} - \ln \left(\frac{3}{2} + \frac{\sqrt{5}}{2} \right) \right] = \frac{9\sqrt{5}}{2} - 6 \ln \left(\frac{3+\sqrt{5}}{2} \right) \end{aligned}$$

35. Area of $\triangle POQ = \frac{1}{2}(r \cos \theta)(r \sin \theta) = \frac{1}{2}r^2 \sin \theta \cos \theta$. Area of region $PQR = \int_{r \cos \theta}^r \sqrt{r^2 - x^2} dx$.

Let $x = r \cos u \Rightarrow dx = -r \sin u du$ for $\theta \leq u \leq \frac{\pi}{2}$. Then we obtain

$$\begin{aligned} \int \sqrt{r^2 - x^2} dx &= \int r \sin u (-r \sin u) du = -r^2 \int \sin^2 u du = -\frac{1}{2}r^2(u - \sin u \cos u) + C \\ &= -\frac{1}{2}r^2 \cos^{-1}(x/r) + \frac{1}{2}x \sqrt{r^2 - x^2} + C \end{aligned}$$

so

$$\begin{aligned} \text{area of region } PQR &= \frac{1}{2} \left[-r^2 \cos^{-1}(x/r) + x \sqrt{r^2 - x^2} \right]_{r \cos \theta}^r \\ &= \frac{1}{2} [0 - (-r^2 \theta + r \cos \theta r \sin \theta)] \\ &= \frac{1}{2} r^2 \theta - \frac{1}{2} r^2 \sin \theta \cos \theta \end{aligned}$$

and thus, (area of sector POR) = (area of $\triangle POQ$) + (area of region PQR) = $\frac{1}{2}r^2\theta$.

36. Let $x = \sqrt{2} \sec \theta$, where $0 \leq \theta < \frac{\pi}{2}$ or $\pi \leq \theta < \frac{3\pi}{2}$, so $dx = \sqrt{2} \sec \theta \tan \theta d\theta$. Then

$$\begin{aligned} \int \frac{dx}{x^4 \sqrt{x^2 - 2}} &= \int \frac{\sqrt{2} \sec \theta \tan \theta d\theta}{4 \sec^4 \theta \sqrt{2} \tan \theta} \\ &= \frac{1}{4} \int \cos^3 \theta d\theta = \frac{1}{4} \int (1 - \sin^2 \theta) \cos \theta d\theta \\ &= \frac{1}{4} \left[\sin \theta - \frac{1}{3} \sin^3 \theta \right] + C \quad [\text{substitute } u = \sin \theta] \\ &= \frac{1}{4} \left[\frac{\sqrt{x^2 - 2}}{x} - \frac{(x^2 - 2)^{3/2}}{3x^3} \right] + C \end{aligned}$$

From the graph, it appears that our answer is reasonable. [Notice that $f(x)$ is large when F increases rapidly and small when F levels out.]

37. From the graph, it appears that the curve $y = x^2 \sqrt{4 - x^2}$ and the line $y = 2 - x$ intersect at about $x = 0.81$ and $x = 2$, with $x^2 \sqrt{4 - x^2} > 2 - x$ on $(0.81, 2)$. So the area bounded by the curve and the line is $A \approx$

$$\int_{0.81}^2 [x^2 \sqrt{4 - x^2} - (2 - x)] dx = \int_{0.81}^2 x^2 \sqrt{4 - x^2} dx - \left[2x - \frac{1}{2}x^2 \right]_{0.81}^2.$$

To evaluate the integral, we put $x = 2 \sin \theta$, where $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Then

$$dx = 2 \cos \theta d\theta, \quad x = 2 \Rightarrow \theta = \sin^{-1} 1 = \frac{\pi}{2}, \quad \text{and } x = 0.81 \Rightarrow \theta = \sin^{-1} 0.405 \approx 0.417. \text{ So}$$

$$\begin{aligned} \int_{0.81}^2 x^2 \sqrt{4 - x^2} dx &\approx \int_{0.417}^{\pi/2} 4 \sin^2 \theta (2 \cos \theta) (2 \cos \theta d\theta) = 4 \int_{0.417}^{\pi/2} \sin^2 2\theta d\theta = 4 \int_{0.417}^{\pi/2} \frac{1}{2} (1 - \cos 4\theta) d\theta \\ &= 2 \left[\theta - \frac{1}{4} \sin 4\theta \right]_{0.417}^{\pi/2} = 2 \left[\left(\frac{\pi}{2} - 0 \right) - \left(0.417 - \frac{1}{4} (0.995) \right) \right] \approx 2.81 \end{aligned}$$

$$\text{Thus, } A \approx 2.81 - \left[\left(2 \cdot 2 - \frac{1}{2} \cdot 2^2 \right) - \left(2 \cdot 0.81 - \frac{1}{2} \cdot 0.81^2 \right) \right] \approx 2.10.$$

38. Let $x = b \tan \theta$, so that $dx = b \sec^2 \theta d\theta$ and $\sqrt{x^2 + b^2} = b \sec \theta$.

$$\begin{aligned} E(P) &= \int_{-a}^{L-a} \frac{\lambda b}{4\pi\epsilon_0 (x^2 + b^2)^{3/2}} dx = \frac{\lambda b}{4\pi\epsilon_0} \int_{\theta_1}^{\theta_2} \frac{1}{(b \sec \theta)^3} b \sec^2 \theta d\theta \\ &= \frac{\lambda}{4\pi\epsilon_0 b} \int_{\theta_1}^{\theta_2} \frac{1}{\sec \theta} d\theta = \frac{\lambda}{4\pi\epsilon_0 b} \int_{\theta_1}^{\theta_2} \cos \theta d\theta = \frac{\lambda}{4\pi\epsilon_0 b} \left[\sin \theta \right]_{\theta_1}^{\theta_2} \\ &= \frac{\lambda}{4\pi\epsilon_0 b} \left[\frac{x}{\sqrt{x^2 + b^2}} \right]_{-a}^{L-a} = \frac{\lambda}{4\pi\epsilon_0 b} \left(\frac{L-a}{\sqrt{(L-a)^2 + b^2}} + \frac{a}{\sqrt{a^2 + b^2}} \right) \end{aligned}$$

39. Let the equation of the large circle be $x^2 + y^2 = R^2$. Then the equation of the small circle is $x^2 + (y - b)^2 = r^2$, where $b = \sqrt{R^2 - r^2}$ is the distance between the centers of the circles. The desired area is

$$\begin{aligned} A &= \int_{-r}^r [(b + \sqrt{r^2 - x^2}) - \sqrt{R^2 - x^2}] dx = 2 \int_0^r (b + \sqrt{r^2 - x^2} - \sqrt{R^2 - x^2}) dx \\ &= 2 \int_0^r b dx + 2 \int_0^r \sqrt{r^2 - x^2} dx - 2 \int_0^r \sqrt{R^2 - x^2} dx \end{aligned}$$

The first integral is just $2br = 2r \sqrt{R^2 - r^2}$. To evaluate the other two integrals, note that

$$\begin{aligned} \int \sqrt{a^2 - x^2} dx &= \int a^2 \cos^2 \theta d\theta \quad [x = a \sin \theta, dx = a \cos \theta d\theta] = \frac{1}{2} a^2 \int (1 + \cos 2\theta) d\theta \\ &= \frac{1}{2} a^2 \left(\theta + \frac{1}{2} \sin 2\theta \right) + C = \frac{1}{2} a^2 (\theta + \sin \theta \cos \theta) + C \\ &= \frac{a^2}{2} \arcsin\left(\frac{x}{a}\right) + \frac{a^2}{2} \left(\frac{x}{a}\right) \frac{\sqrt{a^2 - x^2}}{a} + C = \frac{a^2}{2} \arcsin\left(\frac{x}{a}\right) + \frac{x}{2} \sqrt{a^2 - x^2} + C \end{aligned}$$

so the desired area is

$$\begin{aligned} A &= 2r \sqrt{R^2 - r^2} + \left[r^2 \arcsin(x/r) + x \sqrt{r^2 - x^2} \right]_0^r - \left[R^2 \arcsin(x/R) + x \sqrt{R^2 - x^2} \right]_0^r \\ &= 2r \sqrt{R^2 - r^2} + r^2 \left(\frac{\pi}{2} \right) - \left[R^2 \arcsin(r/R) + r \sqrt{R^2 - r^2} \right] = r \sqrt{R^2 - r^2} + \frac{\pi}{2} r^2 - R^2 \arcsin(r/R) \end{aligned}$$

40. Note that the circular cross-sections of the tank are the same everywhere, so the percentage of the total capacity that is being used is equal to the percentage of any cross-section that is under water. The underwater area is

$$\begin{aligned} A &= 2 \int_{-5}^2 \sqrt{25 - y^2} dy \\ &= \left[25 \arcsin(y/5) + y \sqrt{25 - y^2} \right]_{-5}^2 \quad [\text{substitute } y = 5 \sin \theta] \\ &= 25 \arcsin \frac{2}{5} + 2 \sqrt{21} + \frac{25}{2} \pi \approx 58.72 \text{ ft}^2 \end{aligned}$$

so the fraction of the total capacity in use is $\frac{A}{\pi(5)^2} \approx \frac{58.72}{25\pi} \approx 0.748$ or 74.8%.

41. We use cylindrical shells and assume that $R > r$. $x^2 = r^2 - (y - R)^2 \Rightarrow x = \pm \sqrt{r^2 - (y - R)^2}$, so $g(y) = 2 \sqrt{r^2 - (y - R)^2}$ and

$$\begin{aligned} V &= \int_{R-r}^{R+r} 2\pi y \cdot 2 \sqrt{r^2 - (y - R)^2} dy = \int_{-r}^r 4\pi(u + R) \sqrt{r^2 - u^2} du \quad [\text{where } u = y - R] \\ &= 4\pi \int_{-r}^r u \sqrt{r^2 - u^2} du + 4\pi R \int_{-r}^r \sqrt{r^2 - u^2} du \quad \left[\begin{array}{l} \text{where } u = r \sin \theta, du = r \cos \theta d\theta \\ \text{in the second integral} \end{array} \right] \\ &= 4\pi \left[-\frac{1}{3} (r^2 - u^2)^{3/2} \right]_{-r}^r + 4\pi R \int_{-\pi/2}^{\pi/2} r^2 \cos^2 \theta d\theta = -\frac{4\pi}{3} (0 - 0) + 4\pi R r^2 \int_{-\pi/2}^{\pi/2} \cos^2 \theta d\theta \\ &= 2\pi R r^2 \int_{-\pi/2}^{\pi/2} (1 + \cos 2\theta) d\theta = 2\pi R r^2 \left[\theta + \frac{1}{2} \sin 2\theta \right]_{-\pi/2}^{\pi/2} = 2\pi^2 R r^2 \end{aligned}$$

Another method: Use washers instead of shells, so $V = 8\pi R \int_0^r \sqrt{r^2 - y^2} dy$ as in Exercise 6.2.61(a), but evaluate the integral using $y = r \sin \theta$.

8.4 Integration of Rational Functions by Partial Fractions

1. (a) $\frac{2x}{(x+3)(3x+1)} = \frac{A}{x+3} + \frac{B}{3x+1}$
- (b) $\frac{1}{x^3 + 2x^2 + x} = \frac{1}{x(x^2 + 2x + 1)} = \frac{1}{x(x+1)^2} = \frac{A}{x} + \frac{B}{x+1} + \frac{C}{(x+1)^2}$
2. (a) $\frac{x-1}{x^3 + x^2} = \frac{x-1}{x^2(x+1)} = \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x+1}$
- (b) $\frac{x-1}{x^3 + x} = \frac{x-1}{x(x^2 + 1)} = \frac{A}{x} + \frac{Bx+C}{x^2 + 1}$
3. (a) $\frac{2}{x^2 + 3x - 4} = \frac{2}{(x+4)(x-1)} = \frac{A}{x+4} + \frac{B}{x-1}$
- (b) $x^2 + x + 1$ is irreducible, so $\frac{x^2}{(x-1)(x^2 + x + 1)} = \frac{A}{x-1} + \frac{Bx+C}{x^2 + x + 1}$.

$$4. (a) \frac{x^3}{x^2 + 4x + 3} = x - 4 + \frac{13x + 12}{x^2 + 4x + 3} = x - 4 + \frac{13x + 12}{(x+1)(x+3)} = x - 4 + \frac{A}{x+1} + \frac{B}{x+3}$$

$$(b) \frac{2x+1}{(x+1)^3(x^2+4)^2} = \frac{A}{x+1} + \frac{B}{(x+1)^2} + \frac{C}{(x+1)^3} + \frac{Dx+E}{x^2+4} + \frac{Fx+G}{(x^2+4)^2}$$

$$5. (a) \frac{x^4}{x^4-1} = \frac{(x^4-1)+1}{x^4-1} = 1 + \frac{1}{x^4-1} \quad [\text{or use long division}] = 1 + \frac{1}{(x^2-1)(x^2+1)}$$

$$= 1 + \frac{1}{(x-1)(x+1)(x^2+1)} = 1 + \frac{A}{x-1} + \frac{B}{x+1} + \frac{Cx+D}{x^2+1}$$

$$(b) \frac{t^4+t^2+1}{(t^2+1)(t^2+4)^2} = \frac{At+B}{t^2+1} + \frac{Ct+D}{t^2+4} + \frac{Et+F}{(t^2+4)^2}$$

$$6. (a) \frac{x^4}{(x^3+x)(x^2-x+3)} = \frac{x^4}{x(x^2+1)(x^2-x+3)} = \frac{x^3}{(x^2+1)(x^2-x+3)} = \frac{Ax+B}{x^2+1} + \frac{Cx+D}{x^2-x+3}$$

$$(b) \frac{1}{x^6-x^3} = \frac{1}{x^3(x^3-1)} = \frac{1}{x^3(x-1)(x^2+x+1)} = \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x^3} + \frac{D}{x-1} + \frac{Ex+F}{x^2+x+1}$$

$$7. \int \frac{x}{x-6} dx = \int \frac{(x-6)+6}{x-6} dx = \int \left(1 + \frac{6}{x-6}\right) dx = x + 6 \ln|x-6| + C$$

$$8. \int \frac{r^2}{r+4} dr = \int \left(\frac{r^2-16}{r+4} + \frac{16}{r+4}\right) dr = \int \left(r-4 + \frac{16}{r+4}\right) dr \quad [\text{or use long division}]$$

$$= \frac{1}{2}r^2 - 4r + 16 \ln|r+4| + C$$

$$9. \frac{x-9}{(x+5)(x-2)} = \frac{A}{x+5} + \frac{B}{x-2}. \text{ Multiply both sides by } (x+5)(x-2) \text{ to get } x-9 = A(x-2) + B(x+5).$$

Substituting 2 for x gives $-7 = 7B \Leftrightarrow B = -1$. Substituting -5 for x gives $-14 = -7A \Leftrightarrow A = 2$. Thus,

$$\int \frac{x-9}{(x+5)(x-2)} dx = \int \left(\frac{2}{x+5} + \frac{-1}{x-2}\right) dx = 2 \ln|x+5| - \ln|x-2| + C$$

$$10. \frac{1}{(t+4)(t-1)} = \frac{A}{t+4} + \frac{B}{t-1} \Rightarrow 1 = A(t-1) + B(t+4).$$

$$t=1 \Rightarrow 1=5B \Rightarrow B=\frac{1}{5}. \quad t=-4 \Rightarrow 1=-5A \Rightarrow A=-\frac{1}{5}. \text{ Thus,}$$

$$\int \frac{1}{(t+4)(t-1)} dt = \int \left(\frac{-1/5}{t+4} + \frac{1/5}{t-1}\right) dt = -\frac{1}{5} \ln|t+4| + \frac{1}{5} \ln|t-1| + C \quad \text{or} \quad \frac{1}{5} \ln \left| \frac{t-1}{t+4} \right| + C$$

$$11. \frac{1}{x^2-1} = \frac{1}{(x+1)(x-1)} = \frac{A}{x+1} + \frac{B}{x-1}. \text{ Multiply both sides by } (x+1)(x-1) \text{ to get}$$

$$1 = A(x-1) + B(x+1). \text{ Substituting 1 for } x \text{ gives } 1 = 2B \Leftrightarrow B = \frac{1}{2}.$$

$$\text{Substituting } -1 \text{ for } x \text{ gives } 1 = -2A \Leftrightarrow A = -\frac{1}{2}. \text{ Thus,}$$

$$\int_2^3 \frac{1}{x^2-1} dx = \int_2^3 \left(\frac{-1/2}{x+1} + \frac{1/2}{x-1}\right) dx = \left[-\frac{1}{2} \ln|x+1| + \frac{1}{2} \ln|x-1|\right]_2^3$$

$$= \left(-\frac{1}{2} \ln 4 + \frac{1}{2} \ln 2\right) - \left(-\frac{1}{2} \ln 3 + \frac{1}{2} \ln 1\right) = \frac{1}{2}(\ln 2 + \ln 3 - \ln 4) \quad [\text{or } \frac{1}{2} \ln \frac{3}{2}]$$

$$12. \frac{x-1}{x^2+3x+2} = \frac{A}{x+1} + \frac{B}{x+2}. \text{ Multiply both sides by } (x+1)(x+2) \text{ to get } x-1 = A(x+2) + B(x+1).$$

$$\text{Substituting } -2 \text{ for } x \text{ gives } -3 = -B \Leftrightarrow B = 3. \text{ Substituting } -1 \text{ for } x \text{ gives } -2 = A. \text{ Thus,}$$

$$\int_0^1 \frac{x-1}{x^2+3x+2} dx = \int_0^1 \left(\frac{-2}{x+1} + \frac{3}{x+2}\right) dx = [-2 \ln|x+1| + 3 \ln|x+2|]_0^1$$

$$= (-2 \ln 2 + 3 \ln 3) - (-2 \ln 1 + 3 \ln 2) = 3 \ln 3 - 5 \ln 2 \quad [\text{or } \ln \frac{27}{32}]$$

$$13. \int \frac{ax}{x^2 - bx} dx = \int \frac{ax}{x(x-b)} dx = \int \frac{a}{x-b} dx = a \ln|x-b| + C$$

$$14. \text{ If } a \neq b, \frac{1}{(x+a)(x+b)} = \frac{1}{b-a} \left(\frac{1}{x+a} - \frac{1}{x+b} \right), \text{ so if } a \neq b, \text{ then}$$

$$\int \frac{dx}{(x+a)(x+b)} = \frac{1}{b-a} (\ln|x+a| - \ln|x+b|) + C = \frac{1}{b-a} \ln \left| \frac{x+a}{x+b} \right| + C$$

$$\text{If } a = b, \text{ then } \int \frac{dx}{(x+a)^2} = -\frac{1}{x+a} + C.$$

$$15. \frac{2x+3}{(x+1)^2} = \frac{A}{x+1} + \frac{B}{(x+1)^2} \Rightarrow 2x+3 = A(x+1) + B. \text{ Take } x = -1 \text{ to get } B = 1, \text{ and equate}$$

coefficients of x to get $A = 2$. Now

$$\begin{aligned} \int_0^1 \frac{2x+3}{(x+1)^2} dx &= \int_0^1 \left[\frac{2}{x+1} + \frac{1}{(x+1)^2} \right] dx = \left[2 \ln(x+1) - \frac{1}{x+1} \right]_0^1 \\ &= 2 \ln 2 - \frac{1}{2} - (2 \ln 1 - 1) = 2 \ln 2 + \frac{1}{2} \end{aligned}$$

$$16. \frac{x^3 - 4x - 10}{x^2 - x - 6} = x + 1 + \frac{3x-4}{(x-3)(x+2)}. \text{ Write } \frac{3x-4}{(x-3)(x+2)} = \frac{A}{x-3} + \frac{B}{x+2}. \text{ Then}$$

$$3x-4 = A(x+2) + B(x-3). \text{ Taking } x = 3 \text{ and } x = -2, \text{ we get } 5 = 5A \Leftrightarrow A = 1 \text{ and } -10 = -5B \Leftrightarrow B = 2, \text{ so}$$

$$\begin{aligned} \int_0^1 \frac{x^3 - 4x - 10}{x^2 - x - 6} dx &= \int_0^1 \left(x + 1 + \frac{1}{x-3} + \frac{2}{x+2} \right) dx = \left[\frac{1}{2}x^2 + x + \ln|x-3| + 2 \ln|x+2| \right]_0^1 \\ &= \left(\frac{1}{2} + 1 + \ln 2 + 2 \ln 3 \right) - (0 + 0 + \ln 3 + 2 \ln 2) = \frac{3}{2} + \ln 3 - \ln 2 = \frac{3}{2} + \ln \frac{3}{2} \end{aligned}$$

$$17. \frac{4y^2 - 7y - 12}{y(y+2)(y-3)} = \frac{A}{y} + \frac{B}{y+2} + \frac{C}{y-3} \Rightarrow 4y^2 - 7y - 12 = A(y+2)(y-3) + By(y-3) + Cy(y+2).$$

Setting $y = 0$ gives $-12 = -6A$, so $A = 2$. Setting $y = -2$ gives $18 = 10B$, so $B = \frac{9}{5}$. Setting $y = 3$ gives

$$3 = 15C, \text{ so } C = \frac{1}{5}. \text{ Now}$$

$$\begin{aligned} \int_1^2 \frac{4y^2 - 7y - 12}{y(y+2)(y-3)} dy &= \int_1^2 \left(\frac{2}{y} + \frac{9/5}{y+2} + \frac{1/5}{y-3} \right) dy = \left[2 \ln|y| + \frac{9}{5} \ln|y+2| + \frac{1}{5} \ln|y-3| \right]_1^2 \\ &= 2 \ln 2 + \frac{9}{5} \ln 4 + \frac{1}{5} \ln 1 - 2 \ln 1 - \frac{9}{5} \ln 3 - \frac{1}{5} \ln 2 \\ &= 2 \ln 2 + \frac{18}{5} \ln 2 - \frac{1}{5} \ln 2 - \frac{9}{5} \ln 3 = \frac{27}{5} \ln 2 - \frac{9}{5} \ln 3 = \frac{9}{5} (3 \ln 2 - \ln 3) = \frac{9}{5} \ln \frac{8}{3} \end{aligned}$$

$$18. \frac{x^2 + 2x - 1}{x^3 - x} = \frac{x^2 + 2x - 1}{x(x+1)(x-1)} = \frac{A}{x} + \frac{B}{x+1} + \frac{C}{x-1}. \text{ Multiply both sides by } x(x+1)(x-1) \text{ to get}$$

$$x^2 + 2x - 1 = A(x+1)(x-1) + Bx(x-1) + Cx(x+1). \text{ Substituting } 0 \text{ for } x \text{ gives } -1 = -A \Leftrightarrow A = 1.$$

$$\text{Substituting } -1 \text{ for } x \text{ gives } -2 = 2B \Leftrightarrow B = -1. \text{ Substituting } 1 \text{ for } x \text{ gives } 2 = 2C \Leftrightarrow C = 1. \text{ Thus,}$$

$$\int \frac{x^2 + 2x - 1}{x^3 - x} dx = \int \left(\frac{1}{x} - \frac{1}{x+1} + \frac{1}{x-1} \right) dx = \ln|x| - \ln|x+1| + \ln|x-1| + C = \ln \left| \frac{x(x-1)}{x+1} \right| + C.$$

19. $\frac{1}{(x+5)^2(x-1)} = \frac{A}{x+5} + \frac{B}{(x+5)^2} + \frac{C}{x-1} \Rightarrow 1 = A(x+5)(x-1) + B(x-1) + C(x+5)^2$. Setting $x = -5$ gives $1 = -6B$, so $B = -\frac{1}{6}$. Setting $x = 1$ gives $1 = 36C$, so $C = \frac{1}{36}$. Setting $x = -2$ gives $1 = A(3)(-3) + B(-3) + C(3^2) = -9A - 3B + 9C = -9A + \frac{1}{2} + \frac{1}{4} = -9A + \frac{3}{4}$, so $9A = -\frac{1}{4}$ and $A = -\frac{1}{36}$. Now

$$\begin{aligned}\int \frac{1}{(x+5)^2(x-1)} dx &= \int \left[\frac{-1/36}{x+5} - \frac{1/6}{(x+5)^2} + \frac{1/36}{x-1} \right] dx \\ &= -\frac{1}{36} \ln|x+5| + \frac{1}{6(x+5)} + \frac{1}{36} \ln|x-1| + C\end{aligned}$$

20. $\frac{x^2}{(x-3)(x+2)^2} = \frac{A}{x-3} + \frac{B}{x+2} + \frac{C}{(x+2)^2} \Rightarrow x^2 = A(x+2)^2 + B(x-3)(x+2) + C(x-3)$. Setting $x = 3$ gives $A = \frac{9}{25}$. Take $x = -2$ to get $C = -\frac{4}{5}$, and equate the coefficients of x^2 to get $1 = A + B \Rightarrow B = \frac{16}{25}$. Then

$$\begin{aligned}\int \frac{x^2}{(x-3)(x+2)^2} dx &= \int \left[\frac{9/25}{x-3} + \frac{16/25}{x+2} - \frac{4/5}{(x+2)^2} \right] dx \\ &= \frac{9}{25} \ln|x-3| + \frac{16}{25} \ln|x+2| + \frac{4}{5(x+2)} + C\end{aligned}$$

21. $\frac{5x^2+3x-2}{x^3+2x^2} = \frac{5x^2+3x-2}{x^2(x+2)} = \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x+2}$. Multiply by $x^2(x+2)$ to get $5x^2+3x-2 = Ax(x+2) + B(x+2) + Cx^2$. Set $x = -2$ to get $C = 3$, and take $x = 0$ to get $B = -1$. Equating the coefficients of x^2 gives $5 = A + C \Rightarrow A = 2$. So

$$\int \frac{5x^2+3x-2}{x^3+2x^2} dx = \int \left(\frac{2}{x} - \frac{1}{x^2} + \frac{3}{x+2} \right) dx = 2 \ln|x| + \frac{1}{x} + 3 \ln|x+2| + C.$$

22. $\frac{1}{s^2(s-1)^2} = \frac{A}{s} + \frac{B}{s^2} + \frac{C}{s-1} + \frac{D}{(s-1)^2} \Rightarrow 1 = As(s-1)^2 + B(s-1)^2 + Cs^2(s-1) + Ds^2$. Set $s = 0$, giving $B = 1$. Then set $s = 1$ to get $D = 1$. Equate the coefficients of s^3 to get $0 = A + C$ or $A = -C$, and finally set $s = 2$ to get $1 = 2A + 1 - 4A + 4$ or $A = 2$. Now

$$\int \frac{ds}{s^2(s-1)^2} = \int \left[\frac{2}{s} + \frac{1}{s^2} - \frac{2}{s-1} + \frac{1}{(s-1)^2} \right] ds = 2 \ln|s| - \frac{1}{s} - 2 \ln|s-1| - \frac{1}{s-1} + C.$$

23. $\frac{x^2}{(x+1)^3} = \frac{A}{x+1} + \frac{B}{(x+1)^2} + \frac{C}{(x+1)^3}$. Multiply by $(x+1)^3$ to get $x^2 = A(x+1)^2 + B(x+1) + C$. Setting $x = -1$ gives $C = 1$. Equating the coefficients of x^2 gives $A = 1$, and setting $x = 0$ gives $B = -2$.

$$\text{Now } \int \frac{x^2 dx}{(x+1)^3} = \int \left[\frac{1}{x+1} - \frac{2}{(x+1)^2} + \frac{1}{(x+1)^3} \right] dx = \ln|x+1| + \frac{2}{x+1} - \frac{1}{2(x+1)^2} + C.$$

24. $\frac{x}{x+1} = \frac{(x+1)-1}{x+1} = 1 - \frac{1}{x+1}$, so $\frac{x^3}{(x+1)^3} = \left[1 - \frac{1}{x+1} \right]^3 = 1 - \frac{3}{x+1} + \frac{3}{(x+1)^2} - \frac{1}{(x+1)^3}$. Thus,
- $$\int \frac{x^3}{(x+1)^3} dx = \int \left[1 - \frac{3}{x+1} + \frac{3}{(x+1)^2} - \frac{1}{(x+1)^3} \right] dx = x - 3 \ln|x+1| - \frac{3}{x+1} + \frac{1}{2(x+1)^2} + C.$$

25. $\frac{10}{(x-1)(x^2+9)} = \frac{A}{x-1} + \frac{Bx+C}{x^2+9}$. Multiply both sides by $(x-1)(x^2+9)$ to get

$10 = A(x^2+9) + (Bx+C)(x-1)$ (*). Substituting 1 for x gives $10 = 10A \Leftrightarrow A = 1$. Substituting 0 for x gives $10 = 9A - C \Rightarrow C = 9(1) - 10 = -1$. The coefficients of the x^2 -terms in (*) must be equal, so $0 = A + B \Rightarrow B = -1$. Thus,

$$\int \frac{10}{(x-1)(x^2+9)} dx = \int \left(\frac{1}{x-1} + \frac{-x-1}{x^2+9} \right) dx = \int \left(\frac{1}{x-1} - \frac{x}{x^2+9} - \frac{1}{x^2+9} \right) dx$$

$$= \ln|x-1| - \frac{1}{2} \ln(x^2+9) \quad [\text{let } u = x^2+9] - \frac{1}{3} \tan^{-1} \left(\frac{x}{3} \right) \quad [\text{Formula 10}] + C$$

26. $\frac{x^2-x+6}{x^3+3x} = \frac{x^2-x+6}{x(x^2+3)} = \frac{A}{x} + \frac{Bx+C}{x^2+3}$. Multiply by $x(x^2+3)$ to get

$x^2-x+6 = A(x^2+3) + (Bx+C)x$. Substituting 0 for x gives $6 = 3A \Leftrightarrow A = 2$. The coefficients of the x^2 -terms must be equal, so $1 = A + B \Rightarrow B = 1 - 2 = -1$. The coefficients of the x -terms must be equal, so $-1 = C$. Thus,

$$\int \frac{x^2-x+6}{x^3+3x} dx = \int \left(\frac{2}{x} + \frac{-x-1}{x^2+3} \right) dx = \int \left(\frac{2}{x} - \frac{x}{x^2+3} - \frac{1}{x^2+3} \right) dx$$

$$= 2 \ln|x| - \frac{1}{2} \ln(x^2+3) - \frac{1}{\sqrt{3}} \tan^{-1} \frac{x}{\sqrt{3}} + C$$

27. $\frac{x^3+x^2+2x+1}{(x^2+1)(x^2+2)} = \frac{Ax+B}{x^2+1} + \frac{Cx+D}{x^2+2}$. Multiply both sides by $(x^2+1)(x^2+2)$ to get

$$x^3+x^2+2x+1 = (Ax+B)(x^2+2) + (Cx+D)(x^2+1) \Leftrightarrow$$

$$x^3+x^2+2x+1 = (Ax^3+Bx^2+2Ax+2B) + (Cx^3+Dx^2+Cx+D) \Leftrightarrow$$

$x^3+x^2+2x+1 = (A+C)x^3 + (B+D)x^2 + (2A+C)x + (2B+D)$. Comparing coefficients gives us the following system of equations:

$$A+C=1 \quad (1) \qquad B+D=1 \quad (2)$$

$$2A+C=2 \quad (3) \qquad 2B+D=1 \quad (4)$$

Subtracting equation (1) from equation (3) gives us $A = 1$, so $C = 0$. Subtracting equation (2) from equation (4)

gives us $B = 0$, so $D = 1$. Thus, $I = \int \frac{x^3+x^2+2x+1}{(x^2+1)(x^2+2)} dx = \int \left(\frac{x}{x^2+1} + \frac{1}{x^2+2} \right) dx$. For $\int \frac{x}{x^2+1} dx$,

let $u = x^2+1$ so $du = 2x dx$ and then $\int \frac{x}{x^2+1} dx = \frac{1}{2} \int \frac{1}{u} du = \frac{1}{2} \ln|u| + C = \frac{1}{2} \ln(x^2+1) + C$. For

$\int \frac{1}{x^2+2} dx$, use Formula 10 with $a = \sqrt{2}$. So $\int \frac{1}{x^2+2} dx = \int \frac{1}{x^2+(\sqrt{2})^2} dx = \frac{1}{\sqrt{2}} \tan^{-1} \frac{x}{\sqrt{2}} + C$.

Thus, $I = \frac{1}{2} \ln(x^2+1) + \frac{1}{\sqrt{2}} \tan^{-1} \frac{x}{\sqrt{2}} + C$.

28. $\frac{x^2-2x-1}{(x-1)^2(x^2+1)} = \frac{A}{x-1} + \frac{B}{(x-1)^2} + \frac{Cx+D}{x^2+1} \Rightarrow$

$x^2-2x-1 = A(x-1)(x^2+1) + B(x^2+1) + (Cx+D)(x-1)^2$. Setting $x = 1$ gives $B = -1$.

Equating the coefficients of x^3 gives $A = -C$. Equating the constant terms gives $-1 = -A - 1 + D$, so $D = A$.

and setting $x = 2$ gives $-1 = 5A - 5 - 2A + A$ or $A = 1$. We have

$$\begin{aligned}\int \frac{x^2 - 2x - 1}{(x-1)^2(x^2+1)} dx &= \int \left[\frac{1}{x-1} - \frac{1}{(x-1)^2} - \frac{x-1}{x^2+1} \right] dx \\ &= \ln|x-1| + \frac{1}{x-1} - \frac{1}{2} \ln(x^2+1) + \tan^{-1} x + C\end{aligned}$$

$$\begin{aligned}29. \int \frac{x+4}{x^2+2x+5} dx &= \int \frac{x+1}{x^2+2x+5} dx + \int \frac{3}{x^2+2x+5} dx = \frac{1}{2} \int \frac{(2x+2) dx}{x^2+2x+5} + \int \frac{3 dx}{(x+1)^2+4} \\ &= \frac{1}{2} \ln|x^2+2x+5| + 3 \int \frac{2 du}{4(u^2+1)} \quad \left[\begin{array}{l} \text{where } x+1=2u, \\ \text{and } dx=2 du \end{array} \right] \\ &= \frac{1}{2} \ln(x^2+2x+5) + \frac{3}{2} \tan^{-1} u + C = \frac{1}{2} \ln(x^2+2x+5) + \frac{3}{2} \tan^{-1} \left(\frac{x+1}{2} \right) + C\end{aligned}$$

$$\begin{aligned}30. \frac{x^3 - 2x^2 + x + 1}{x^4 + 5x^2 + 4} &= \frac{x^3 - 2x^2 + x + 1}{(x^2+1)(x^2+4)} = \frac{Ax+B}{x^2+1} + \frac{Cx+D}{x^2+4} \Rightarrow \\ x^3 - 2x^2 + x + 1 &= (Ax+B)(x^2+4) + (Cx+D)(x^2+1). \text{ Equating coefficients gives } A+C=1, \\ B+D &= -2, 4A+C=1, 4B+D=1 \Rightarrow A=0, C=1, B=1, D=-3. \text{ Now} \\ \int \frac{x^3 - 2x^2 + x + 1}{x^4 + 5x^2 + 4} dx &= \int \frac{dx}{x^2+1} + \int \frac{x-3}{x^2+4} dx = \tan^{-1} x + \frac{1}{2} \ln(x^2+4) - \frac{3}{2} \tan^{-1}(x/2) + C.\end{aligned}$$

$$\begin{aligned}31. \frac{1}{x^3-1} &= \frac{1}{(x-1)(x^2+x+1)} = \frac{A}{x-1} + \frac{Bx+C}{x^2+x+1} \Rightarrow 1 = A(x^2+x+1) + (Bx+C)(x-1). \\ \text{Take } x &= 1 \text{ to get } A = \frac{1}{3}. \text{ Equating coefficients of } x^2 \text{ and then comparing the constant terms, we get } 0 = \frac{1}{3} + B, \\ 1 &= \frac{1}{3} - C, \text{ so } B = -\frac{1}{3}, C = -\frac{2}{3} \Rightarrow\end{aligned}$$

$$\begin{aligned}\int \frac{1}{x^3-1} dx &= \int \frac{\frac{1}{3}}{x-1} dx + \int \frac{-\frac{1}{3}x - \frac{2}{3}}{x^2+x+1} dx = \frac{1}{3} \ln|x-1| - \frac{1}{3} \int \frac{x+2}{x^2+x+1} dx \\ &= \frac{1}{3} \ln|x-1| - \frac{1}{3} \int \frac{x+1/2}{x^2+x+1} dx - \frac{1}{3} \int \frac{(3/2) dx}{(x+1/2)^2+3/4} \\ &= \frac{1}{3} \ln|x-1| - \frac{1}{6} \ln(x^2+x+1) - \frac{1}{2} \left(\frac{2}{\sqrt{3}} \right) \tan^{-1} \left(\frac{x+\frac{1}{2}}{\sqrt{3}/2} \right) + K \\ &= \frac{1}{3} \ln|x-1| - \frac{1}{6} \ln(x^2+x+1) - \frac{1}{\sqrt{3}} \tan^{-1} \left(\frac{1}{\sqrt{3}}(2x+1) \right) + K\end{aligned}$$

$$\begin{aligned}32. \int_0^1 \frac{x}{x^2+4x+13} dx &= \int_0^1 \frac{\frac{1}{2}(2x+4)}{x^2+4x+13} dx - 2 \int_0^1 \frac{dx}{(x+2)^2+9} \\ &= \frac{1}{2} \int_{13}^{18} \frac{dy}{y} - 2 \int_{2/3}^1 \frac{3 du}{9u^2+9} \quad \left[\begin{array}{l} \text{where } y = x^2+4x+13, dy = (2x+4) dx, \\ x+2 = 3u, \text{ and } dx = 3 du \end{array} \right] \\ &= \frac{1}{2} [\ln y]_{13}^{18} - \frac{2}{3} [\tan^{-1} u]_{2/3}^1 = \frac{1}{2} \ln \frac{18}{13} - \frac{2}{3} \left(\frac{\pi}{4} - \tan^{-1} \left(\frac{2}{3} \right) \right) \\ &= \frac{1}{2} \ln \frac{18}{13} - \frac{\pi}{6} + \frac{2}{3} \tan^{-1} \left(\frac{2}{3} \right)\end{aligned}$$

33. Let $u = x^3 + 3x^2 + 4$. Then $du = 3(x^2 + 2x) dx \Rightarrow$

$$\int_2^5 \frac{x^2 + 2x}{x^3 + 3x^2 + 4} dx = \frac{1}{3} \int_{24}^{204} \frac{du}{u} = \frac{1}{3} [\ln u]_{24}^{204} = \frac{1}{3} (\ln 204 - \ln 24) = \frac{1}{3} \ln \frac{204}{24} = \frac{1}{3} \ln \frac{17}{2}.$$

34. $\frac{x^3}{x^3 + 1} = \frac{(x^3 + 1) - 1}{x^3 + 1} = 1 - \frac{1}{x^3 + 1} = 1 - \left(\frac{A}{x+1} + \frac{Bx+C}{x^2-x+1} \right) \Rightarrow$

$1 = A(x^2 - x + 1) + (Bx + C)(x + 1)$. Equate the terms of degree 2, 1 and 0 to get $0 = A + B$,

$0 = -A + B + C$, $1 = A + C$. Solve the three equations to get $A = \frac{1}{3}$, $B = -\frac{1}{3}$, and $C = \frac{2}{3}$. So

$$\begin{aligned} \int \frac{x^3}{x^3 + 1} dx &= \int \left[1 - \frac{\frac{1}{3}}{x+1} + \frac{\frac{1}{3}x - \frac{2}{3}}{x^2 - x + 1} \right] dx \\ &= x - \frac{1}{3} \ln|x+1| + \frac{1}{6} \int \frac{2x-1}{x^2-x+1} dx - \frac{1}{2} \int \frac{dx}{(x-\frac{1}{2})^2 + \frac{3}{4}} \\ &= x - \frac{1}{3} \ln|x+1| + \frac{1}{6} \ln(x^2 - x + 1) - \frac{1}{\sqrt{3}} \tan^{-1} \left(\frac{1}{\sqrt{3}} (2x-1) \right) + K \end{aligned}$$

35. $\frac{1}{x^4 - x^2} = \frac{1}{x^2(x-1)(x+1)} = \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x-1} + \frac{D}{x+1}$. Multiply by $x^2(x-1)(x+1)$ to get

$1 = Ax(x-1)(x+1) + B(x-1)(x+1) + Cx^2(x+1) + Dx^2(x-1)$. Setting $x = 1$ gives $C = \frac{1}{2}$, taking

$x = -1$ gives $D = -\frac{1}{2}$. Equating the coefficients of x^3 gives $0 = A + C + D = A$. Finally, setting $x = 0$ yields

$$B = -1. \text{ Now } \int \frac{dx}{x^4 - x^2} = \int \left[\frac{-1}{x^2} + \frac{1/2}{x-1} - \frac{1/2}{x+1} \right] dx = \frac{1}{x} + \frac{1}{2} \ln \left| \frac{x-1}{x+1} \right| + C.$$

36. Let $u = x^4 + 5x^2 + 4 \Rightarrow du = (4x^3 + 10x) dx = 2(2x^3 + 5x) dx$, so

$$\int_0^1 \frac{2x^3 + 5x}{x^4 + 5x^2 + 4} dx = \frac{1}{2} \int_4^{10} \frac{du}{u} = \frac{1}{2} [\ln|u|]_4^{10} = \frac{1}{2} (\ln 10 - \ln 4) = \frac{1}{2} \ln \frac{5}{2}.$$

37. $\int \frac{x-3}{(x^2+2x+4)^2} dx = \int \frac{x-3}{[(x+1)^2+3]^2} dx = \int \frac{u-4}{(u^2+3)^2} du$ [with $u = x+1$]

$$\begin{aligned} &= \int \frac{u du}{(u^2+3)^2} - 4 \int \frac{du}{(u^2+3)^2} = \frac{1}{2} \int \frac{dv}{v^2} - 4 \int \frac{\sqrt{3} \sec^2 \theta d\theta}{9 \sec^4 \theta} \quad \left[\begin{array}{l} v = u^2 + 3 \text{ in the first integral;} \\ u = \sqrt{3} \tan \theta \text{ in the second} \end{array} \right] \\ &= \frac{-1}{(2v)} - \frac{4\sqrt{3}}{9} \int \cos^2 \theta d\theta = \frac{-1}{2(u^2+3)} - \frac{2\sqrt{3}}{9} (\theta + \sin \theta \cos \theta) + C \\ &= \frac{-1}{2(x^2+2x+4)} - \frac{2\sqrt{3}}{9} \left[\tan^{-1} \left(\frac{x+1}{\sqrt{3}} \right) + \frac{\sqrt{3}(x+1)}{x^2+2x+4} \right] + C \\ &= \frac{-1}{2(x^2+2x+4)} - \frac{2\sqrt{3}}{9} \tan^{-1} \left(\frac{x+1}{\sqrt{3}} \right) - \frac{2(x+1)}{3(x^2+2x+4)} + C \end{aligned}$$

38. $\frac{x^4+1}{x(x^2+1)^2} = \frac{A}{x} + \frac{Bx+C}{x^2+1} + \frac{Dx+E}{(x^2+1)^2} \Rightarrow x^4+1 = A(x^2+1)^2 + (Bx+C)x(x^2+1) + (Dx+E)x$.

Setting $x = 0$ gives $A = 1$, and equating the coefficients of x^4 gives $1 = A + B$, so $B = 0$. Now

$$\frac{C}{x^2+1} + \frac{Dx+E}{(x^2+1)^2} = \frac{x^4+1}{x(x^2+1)^2} - \frac{1}{x} = \frac{1}{x} \left[\frac{x^4+1-(x^4+2x^2+1)}{(x^2+1)^2} \right] = \frac{-2x}{(x^2+1)^2}, \text{ so we can take } C=0,$$

$$D=-2, \text{ and } E=0. \text{ Hence, } \int \frac{x^4+1}{x(x^2+1)^2} dx = \int \left[\frac{1}{x} - \frac{2x}{(x^2+1)^2} \right] dx = \ln|x| + \frac{1}{x^2+1} + C.$$

39. Let $u = \sqrt{x+1}$. Then $x = u^2 - 1$, $dx = 2u du \Rightarrow$

$$\int \frac{dx}{x\sqrt{x+1}} = \int \frac{2u du}{(u^2-1)u} = 2 \int \frac{du}{u^2-1} = \ln \left| \frac{u-1}{u+1} \right| + C = \ln \left| \frac{\sqrt{x+1}-1}{\sqrt{x+1}+1} \right| + C.$$

40. Let $u = \sqrt{x+2}$. Then $x = u^2 - 2$, $dx = 2u du \Rightarrow$

$$I = \int \frac{dx}{x-\sqrt{x+2}} = \int \frac{2u du}{u^2-2-u} = 2 \int \frac{u du}{u^2-u-2} \text{ and } \frac{u}{u^2-u-2} = \frac{A}{u-2} + \frac{B}{u+1} \Rightarrow$$

$u = A(u+1) + B(u-2)$. Substituting -1 for u gives $-1 = -3B \Leftrightarrow B = \frac{1}{3}$ and substituting 2 for u gives

$$2 = 3A \Leftrightarrow A = \frac{2}{3}. \text{ Thus,}$$

$$\begin{aligned} I &= \frac{2}{3} \int \left[\frac{2}{u-2} + \frac{1}{u+1} \right] du = \frac{2}{3} (2 \ln|u-2| + \ln|u+1|) + C \\ &= \frac{2}{3} [2 \ln|\sqrt{x+2}-2| + \ln(\sqrt{x+2}+1)] + C \end{aligned}$$

41. Let $u = \sqrt{x}$, so $u^2 = x$ and $dx = 2u du$. Thus,

$$\begin{aligned} \int_9^{16} \frac{\sqrt{x}}{x-4} dx &= \int_3^4 \frac{u}{u^2-4} 2u du = 2 \int_3^4 \frac{u^2}{u^2-4} du = 2 \int_3^4 \left(1 + \frac{4}{u^2-4} \right) du \quad [\text{by long division}] \\ &= 2 + 8 \int_3^4 \frac{du}{(u+2)(u-2)}. (*) \end{aligned}$$

Multiply $\frac{1}{(u+2)(u-2)} = \frac{A}{u+2} + \frac{B}{u-2}$ by $(u+2)(u-2)$ to get $1 = A(u-2) + B(u+2)$. Equating coefficients we get $A+B=0$ and $-2A+2B=1$. Solving gives us $B = \frac{1}{4}$ and $A = -\frac{1}{4}$, so

$$\frac{1}{(u+2)(u-2)} = \frac{-1/4}{u+2} + \frac{1/4}{u-2} \text{ and } (*) \text{ is}$$

$$\begin{aligned} 2 + 8 \int_3^4 \left(\frac{-1/4}{u+2} + \frac{1/4}{u-2} \right) du &= 2 + 8 \left[-\frac{1}{4} \ln|u+2| + \frac{1}{4} \ln|u-2| \right]_3^4 \\ &= 2 + \left[2 \ln|u-2| - 2 \ln|u+2| \right]_3^4 = 2 + 2 \left[\ln \left| \frac{u-2}{u+2} \right| \right]_3^4 \\ &= 2 + 2 \left(\ln \frac{2}{6} - \ln \frac{1}{5} \right) = 2 + 2 \ln \frac{2/6}{1/5} \\ &= 2 + 2 \ln \frac{5}{3} \text{ or } 2 + \ln \left(\frac{5}{3} \right)^2 = 2 + \ln \frac{25}{9} \end{aligned}$$

42. Let $u = \sqrt[3]{x}$. Then $x = u^3$, $dx = 3u^2 du \Rightarrow$

$$\begin{aligned} \int_0^1 \frac{1}{1+\sqrt[3]{x}} dx &= \int_0^1 \frac{3u^2 du}{1+u} = \int_0^1 \left(3u - 3 + \frac{3}{1+u} \right) du = \left[\frac{3}{2}u^2 - 3u + 3 \ln(1+u) \right]_0^1 \\ &= 3 \left(\ln 2 - \frac{1}{2} \right) \end{aligned}$$

43. Let $u = \sqrt[3]{x^2 + 1}$. Then $x^2 = u^3 - 1$, $2x dx = 3u^2 du \Rightarrow$

$$\begin{aligned}\int \frac{x^3 dx}{\sqrt[3]{x^2 + 1}} &= \int \frac{(u^3 - 1) \frac{3}{2} u^2 du}{u} = \frac{3}{2} \int (u^4 - u) du = \frac{3}{10} u^5 - \frac{3}{4} u^2 + C \\ &= \frac{3}{10} (x^2 + 1)^{5/3} - \frac{3}{4} (x^2 + 1)^{2/3} + C\end{aligned}$$

44. Let $u = \sqrt{x}$. Then $x = u^2$, $dx = 2u du \Rightarrow$

$$\int_{1/3}^3 \frac{\sqrt{x}}{x^2 + x} dx = \int_{1/\sqrt{3}}^{\sqrt{3}} \frac{u \cdot 2u du}{u^4 + u^2} = 2 \int_{1/\sqrt{3}}^{\sqrt{3}} \frac{du}{u^2 + 1} = 2 [\tan^{-1} u]_{1/\sqrt{3}}^{\sqrt{3}} = 2 \left(\frac{\pi}{3} - \frac{\pi}{6} \right) = \frac{\pi}{3}$$

45. If we were to substitute $u = \sqrt{x}$, then the square root would disappear but a cube root would remain. On the other hand, the substitution $u = \sqrt[3]{x}$ would eliminate the cube root but leave a square root. We can eliminate both roots by means of the substitution $u = \sqrt[6]{x}$. (Note that 6 is the least common multiple of 2 and 3.)

Let $u = \sqrt[6]{x}$. Then $x = u^6$, so $dx = 6u^5 du$ and $\sqrt{x} = u^3$, $\sqrt[3]{x} = u^2$. Thus,

$$\begin{aligned}\int \frac{dx}{\sqrt{x} - \sqrt[3]{x}} &= \int \frac{6u^5 du}{u^3 - u^2} = 6 \int \frac{u^5}{u^2(u-1)} du = 6 \int \frac{u^3}{u-1} du \\ &= 6 \int \left(u^2 + u + 1 + \frac{1}{u-1} \right) du \quad [\text{by long division}] \\ &= 6 \left(\frac{1}{3} u^3 + \frac{1}{2} u^2 + u + \ln |u-1| \right) + C = 2\sqrt{x} + 3\sqrt[3]{x} + 6\sqrt[6]{x} + 6 \ln |\sqrt[6]{x} - 1| + C\end{aligned}$$

46. Let $u = \sqrt[12]{x}$. Then $x = u^{12}$, $dx = 12u^{11} du \Rightarrow$

$$\begin{aligned}\int \frac{dx}{\sqrt[3]{x} + \sqrt[4]{x}} &= \int \frac{12u^{11} du}{u^4 + u^3} = 12 \int \frac{u^8 du}{u+1} = 12 \int \left(u^7 - u^6 + u^5 - u^4 + u^3 - u^2 + u - 1 + \frac{1}{u+1} \right) du \\ &= \frac{3}{2} u^8 - \frac{12}{7} u^7 + 2u^6 - \frac{12}{5} u^5 + 3u^4 - 4u^3 + 6u^2 - 12u + 12 \ln |u+1| + C \\ &= \frac{3}{2} x^{2/3} - \frac{12}{7} x^{7/12} + 2\sqrt{x} - \frac{12}{5} x^{5/12} + 3\sqrt[3]{x} - 4\sqrt[4]{x} + 6\sqrt[6]{x} - 12\sqrt[12]{x} + 12 \ln (\sqrt[12]{x} + 1) + C\end{aligned}$$

47. Let $u = e^x$. Then $x = \ln u$, $dx = \frac{du}{u} \Rightarrow$

$$\begin{aligned}\int \frac{e^{2x} dx}{e^{2x} + 3e^x + 2} &= \int \frac{u^2 (du/u)}{u^2 + 3u + 2} = \int \frac{u du}{(u+1)(u+2)} = \int \left[\frac{-1}{u+1} + \frac{2}{u+2} \right] du \\ &= 2 \ln |u+2| - \ln |u+1| + C = \ln [(e^x + 2)^2 / (e^x + 1)] + C\end{aligned}$$

48. Let $u = \sin x$. Then $du = \cos x dx \Rightarrow$

$$\begin{aligned}\int \frac{\cos x dx}{\sin^2 x + \sin x} &= \int \frac{du}{u^2 + u} = \int \frac{du}{u(u+1)} = \int \left[\frac{1}{u} - \frac{1}{u+1} \right] du \\ &= \ln \left| \frac{u}{u+1} \right| + C = \ln \left| \frac{\sin x}{1 + \sin x} \right| + C\end{aligned}$$

49. Let $u = \ln(x^2 - x + 2)$, $dv = dx$. Then $du = \frac{2x-1}{x^2-x+2} dx$, $v = x$, and (by integration by parts)

$$\begin{aligned} \int \ln(x^2 - x + 2) dx &= x \ln(x^2 - x + 2) - \int \frac{2x^2 - x}{x^2 - x + 2} dx = x \ln(x^2 - x + 2) - \int \left(2 + \frac{x-4}{x^2-x+2} \right) dx \\ &= x \ln(x^2 - x + 2) - 2x - \int \frac{\frac{1}{2}(2x-1)}{x^2-x+2} dx + \frac{7}{2} \int \frac{dx}{(x-\frac{1}{2})^2 + \frac{7}{4}} \\ &= x \ln(x^2 - x + 2) - 2x - \frac{1}{2} \ln(x^2 - x + 2) + \frac{7}{2} \int \frac{\frac{\sqrt{7}}{2} du}{\frac{7}{4}(u^2 + 1)} \quad \left[\begin{array}{l} \text{where } x - \frac{1}{2} = \frac{\sqrt{7}}{2} u, \\ dx = \frac{\sqrt{7}}{2} du, \\ (x - \frac{1}{2})^2 + \frac{7}{4} = \frac{7}{4}(u^2 + 1) \end{array} \right] \\ &= (x - \frac{1}{2}) \ln(x^2 - x + 2) - 2x + \sqrt{7} \tan^{-1} u + C \\ &= (x - \frac{1}{2}) \ln(x^2 - x + 2) - 2x + \sqrt{7} \tan^{-1} \frac{2x-1}{\sqrt{7}} + C \end{aligned}$$

50. Let $u = \tan^{-1} x$, $dv = x dx \Rightarrow du = dx/(1+x^2)$, $v = \frac{1}{2}x^2$.

Then $\int x \tan^{-1} x dx = \frac{1}{2}x^2 \tan^{-1} x - \frac{1}{2} \int \frac{x^2}{1+x^2} dx$. To evaluate the last integral, use long division or observe

$$\text{that } \int \frac{x^2}{1+x^2} dx = \int \frac{(1+x^2) - 1}{1+x^2} dx = \int 1 dx - \int \frac{1}{1+x^2} dx = x - \tan^{-1} x + C_1. \text{ So}$$

$$\int x \tan^{-1} x dx = \frac{1}{2}x^2 \tan^{-1} x - \frac{1}{2}(x - \tan^{-1} x + C_1) = \frac{1}{2}(x^2 \tan^{-1} x + \tan^{-1} x - x) + C.$$

51.

From the graph, we see that the integral will be negative, and we guess that the area is about the same as that of a rectangle with width 2 and height 0.3, so we estimate the integral to be $-(2 \cdot 0.3) = -0.6$. Now

$$\begin{aligned} \frac{1}{x^2 - 2x - 3} &= \frac{1}{(x-3)(x+1)} = \frac{A}{x-3} + \frac{B}{x+1} \Leftrightarrow \\ 1 &= (A+B)x + A - 3B, \text{ so } A = -B \text{ and } A - 3B = 1 \Leftrightarrow A = \frac{1}{4} \\ \text{and } B &= -\frac{1}{4}, \text{ so the integral becomes} \end{aligned}$$

$$\begin{aligned} \int_0^2 \frac{dx}{x^2 - 2x - 3} &= \frac{1}{4} \int_0^2 \frac{dx}{x-3} - \frac{1}{4} \int_0^2 \frac{dx}{x+1} = \frac{1}{4} [\ln|x-3| - \ln|x+1|]_0^2 \\ &= \frac{1}{4} \left[\ln \left| \frac{x-3}{x+1} \right| \right]_0^2 = \frac{1}{4} (\ln \frac{1}{3} - \ln 3) = -\frac{1}{2} \ln 3 \approx -0.55 \end{aligned}$$

52. $\frac{1}{x^3 - 2x^2} = \frac{1}{x^2(x-2)} = \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x-2} \Rightarrow 1 = (A+C)x^2 + (B-2A)x - 2B$, so $A+C = B-2A = 0$

and $-2B = 1 \Rightarrow B = -\frac{1}{2}$, $A = -\frac{1}{4}$, and $C = \frac{1}{4}$. So the general antiderivative of $\frac{1}{x^3 - 2x^2}$ is

$$\begin{aligned} \int \frac{dx}{x^3 - 2x^2} &= -\frac{1}{4} \int \frac{dx}{x} - \frac{1}{2} \int \frac{dx}{x^2} + \frac{1}{4} \int \frac{dx}{x-2} \\ &= -\frac{1}{4} \ln|x| - \frac{1}{2}(-1/x) + \frac{1}{4} \ln|x-2| + C \\ &= \frac{1}{4} \ln \left| \frac{x-2}{x} \right| + \frac{1}{2x} + C \end{aligned}$$

We plot this function with $C = 0$ on the same screen as $y = \frac{1}{x^3 - 2x^2}$.

$$\begin{aligned} 53. \int \frac{dx}{x^2 - 2x} &= \int \frac{dx}{(x-1)^2 - 1} = \int \frac{du}{u^2 - 1} \quad [\text{put } u = x - 1] \\ &= \frac{1}{2} \ln \left| \frac{u-1}{u+1} \right| + C \quad [\text{by Equation 6}] = \frac{1}{2} \ln \left| \frac{x-2}{x} \right| + C \end{aligned}$$

$$\begin{aligned} 54. \int \frac{(2x+1)dx}{4x^2+12x-7} &= \frac{1}{4} \int \frac{(8x+12)dx}{4x^2+12x-7} - \int \frac{2dx}{(2x+3)^2-16} \\ &= \frac{1}{4} \ln |4x^2+12x-7| - \int \frac{du}{u^2-16} \quad [\text{put } u = 2x+3] \\ &= \frac{1}{4} \ln |4x^2+12x-7| - \frac{1}{8} \ln |(u-4)/(u+4)| + C \quad [\text{by Equation 6}] \\ &= \frac{1}{4} \ln |4x^2+12x-7| - \frac{1}{8} \ln |(2x-1)/(2x+7)| + C \end{aligned}$$

55. (a) If $t = \tan\left(\frac{x}{2}\right)$, then $\frac{x}{2} = \tan^{-1} t$. The figure gives

$$\cos\left(\frac{x}{2}\right) = \frac{1}{\sqrt{1+t^2}} \text{ and } \sin\left(\frac{x}{2}\right) = \frac{t}{\sqrt{1+t^2}}.$$

$$(b) \cos x = \cos\left(2 \cdot \frac{x}{2}\right) = 2 \cos^2\left(\frac{x}{2}\right) - 1$$

$$= 2 \left(\frac{1}{\sqrt{1+t^2}} \right)^2 - 1 = \frac{2}{1+t^2} - 1 = \frac{1-t^2}{1+t^2}$$

$$\sin x = \sin\left(2 \cdot \frac{x}{2}\right) = 2 \sin\left(\frac{x}{2}\right) \cos\left(\frac{x}{2}\right) = 2 \frac{t}{\sqrt{1+t^2}} \frac{1}{\sqrt{1+t^2}} = \frac{2t}{1+t^2}$$

$$(c) \frac{x}{2} = \arctan t \Rightarrow x = 2 \arctan t \Rightarrow dx = \frac{2}{1+t^2} dt$$

56. Let $t = \tan(x/2)$. Then, using Exercise 55, $dx = \frac{2}{1+t^2} dt$, $\sin x = \frac{2t}{1+t^2} \Rightarrow$

$$\begin{aligned} \int \frac{dx}{3-5\sin x} &= \int \frac{2 dt/(1+t^2)}{3-10t/(1+t^2)} = \int \frac{2 dt}{3(1+t^2)-10t} = 2 \int \frac{dt}{3t^2-10t+3} \\ &= \frac{1}{4} \int \left[\frac{1}{t-3} - \frac{3}{3t-1} \right] dt = \frac{1}{4} (\ln |t-3| - \ln |3t-1|) + C = \frac{1}{4} \ln \left| \frac{\tan(x/2)-3}{3\tan(x/2)-1} \right| + C \end{aligned}$$

57. Let $t = \tan(x/2)$. Then, using the expressions in Exercise 55, we have

$$\begin{aligned} \int \frac{1}{3\sin x - 4\cos x} dx &= \int \frac{1}{3\left(\frac{2t}{1+t^2}\right) - 4\left(\frac{1-t^2}{1+t^2}\right)} \frac{2 dt}{1+t^2} = 2 \int \frac{dt}{3(2t) - 4(1-t^2)} = \int \frac{dt}{2t^2 + 3t - 2} \\ &= \int \frac{dt}{(2t-1)(t+2)} = \int \left[\frac{2}{5} \frac{1}{2t-1} - \frac{1}{5} \frac{1}{t+2} \right] dt \quad [\text{using partial fractions}] \\ &= \frac{1}{5} [\ln |2t-1| - \ln |t+2|] + C = \frac{1}{5} \ln \left| \frac{2t-1}{t+2} \right| + C = \frac{1}{5} \ln \left| \frac{2\tan(x/2)-1}{\tan(x/2)+2} \right| + C \end{aligned}$$

58. Let $t = \tan(x/2)$. Then, by Exercise 55,

$$\begin{aligned} \int_{\pi/3}^{\pi/2} \frac{dx}{1+\sin x - \cos x} &= \int_{1/\sqrt{3}}^1 \frac{2dt/(1+t^2)}{1+2t/(1+t^2) - (1-t^2)/(1+t^2)} = \int_{1/\sqrt{3}}^1 \frac{2dt}{1+t^2+2t-1+t^2} \\ &= \int_{1/\sqrt{3}}^1 \left[\frac{1}{t} - \frac{1}{t+1} \right] dt = [\ln t - \ln(t+1)]_{1/\sqrt{3}}^1 = \ln \frac{1}{2} - \ln \frac{1}{\sqrt{3}+1} = \ln \frac{\sqrt{3}+1}{2} \end{aligned}$$

59. Let $t = \tan(x/2)$. Then, by Exercise 55,

$$\begin{aligned}\int \frac{dx}{2 \sin x + \sin 2x} &= \frac{1}{2} \int \frac{dx}{\sin x + \sin x \cos x} = \frac{1}{2} \int \frac{2 dt/(1+t^2)}{2t/(1+t^2) + 2t(1-t^2)/(1+t^2)^2} \\ &= \frac{1}{2} \int \frac{(1+t^2) dt}{t(1+t^2) + t(1-t^2)} = \frac{1}{4} \int \frac{(1+t^2) dt}{t} = \frac{1}{4} \int \left(\frac{1}{t} + t \right) dt \\ &= \frac{1}{4} \ln |t| + \frac{1}{8} t^2 + C = \frac{1}{4} \ln \left| \tan\left(\frac{1}{2}x\right) \right| + \frac{1}{8} \tan^2\left(\frac{1}{2}x\right) + C\end{aligned}$$

60. $x^2 - 6x + 8 = (x-3)^2 - 1$ is positive for $5 \leq x \leq 10$, so

$$\begin{aligned}\text{area} &= \int_5^{10} \frac{dx}{(x-3)^2 - 1} = \int_2^7 \frac{du}{u^2 - 1} \quad [\text{put } u = x-3] = \left[\frac{1}{2} \ln \left| \frac{u-1}{u+1} \right| \right]_2^7 \\ &= \frac{1}{2} \ln \frac{3}{4} - \frac{1}{2} \ln \frac{1}{3} = \frac{1}{2} (\ln 3 - 2 \ln 2 + \ln 3) = \ln 3 - \ln 2 = \ln \frac{3}{2}\end{aligned}$$

61. $\frac{x+1}{x-1} = 1 + \frac{2}{x-1} > 0$ for $2 \leq x \leq 3$, so

$$\text{area} = \int_2^3 \left[1 + \frac{2}{x-1} \right] dx = \left[x + 2 \ln |x-1| \right]_2^3 = (3 + 2 \ln 2) - (2 + 2 \ln 1) = 1 + 2 \ln 2.$$

62. (a) We use disks, so the volume is $V = \pi \int_0^1 \left[\frac{1}{x^2 + 3x + 2} \right]^2 dx = \pi \int_0^1 \frac{dx}{(x+1)^2(x+2)^2}$. To evaluate the

integral, we use partial fractions: $\frac{1}{(x+1)^2(x+2)^2} = \frac{A}{x+1} + \frac{B}{(x+1)^2} + \frac{C}{x+2} + \frac{D}{(x+2)^2} \Rightarrow$

$1 = A(x+1)(x+2)^2 + B(x+2)^2 + C(x+1)^2(x+2) + D(x+1)^2$. We set $x = -1$, giving $B = 1$, then set $x = -2$, giving $D = 1$. Now equating coefficients of x^3 gives $A = -C$, and then equating constants gives $1 = 4A + 4 + 2(-A) + 1 \Rightarrow A = -2 \Rightarrow C = 2$. So the expression becomes

$$\begin{aligned}V &= \pi \int_0^1 \left[\frac{-2}{x+1} + \frac{1}{(x+1)^2} + \frac{2}{x+2} + \frac{1}{(x+2)^2} \right] dx = \pi \left[2 \ln \left| \frac{x+2}{x+1} \right| - \frac{1}{x+1} - \frac{1}{x+2} \right]_0^1 \\ &= \pi \left[\left(2 \ln \frac{3}{2} - \frac{1}{2} - \frac{1}{3} \right) - \left(2 \ln 2 - 1 - \frac{1}{2} \right) \right] = \pi \left(2 \ln \frac{3/2}{2} + \frac{2}{3} \right) = \pi \left(\frac{2}{3} + \ln \frac{9}{16} \right)\end{aligned}$$

(b) In this case, we use cylindrical shells, so the volume is $V = 2\pi \int_0^1 \frac{x dx}{x^2 + 3x + 2} = 2\pi \int_0^1 \frac{x dx}{(x+1)(x+2)}$.

We use partial fractions to simplify the integrand: $\frac{x}{(x+1)(x+2)} = \frac{A}{x+1} + \frac{B}{x+2} \Rightarrow$

$x = (A+B)x + 2A+B$. So $A+B=1$ and $2A+B=0 \Rightarrow A=-1$ and $B=2$. So the volume is

$$\begin{aligned}2\pi \int_0^1 \left[\frac{-1}{x+1} + \frac{2}{x+2} \right] dx &= 2\pi \left[-\ln |x+1| + 2 \ln |x+2| \right]_0^1 \\ &= 2\pi (-\ln 2 + 2 \ln 3 + \ln 1 - 2 \ln 2) = 2\pi (2 \ln 3 - 3 \ln 2) = 2\pi \ln \frac{9}{8}\end{aligned}$$

63. $\frac{P+S}{P[(r-1)P-S]} = \frac{A}{P} + \frac{B}{(r-1)P-S} \Rightarrow P+S = A[(r-1)P-S] + BP = [(r-1)A+B]P - AS$

$\Rightarrow (r-1)A+B=1, -A=1 \Rightarrow A=-1, B=r$. Now

$$t = \int \frac{P+S}{P[(r-1)P-S]} dP = \int \left[\frac{-1}{P} + \frac{r}{(r-1)P-S} \right] dP = -\int \frac{dP}{P} + \frac{r}{r-1} \int \frac{r-1}{(r-1)P-S} dP$$

so $t = -\ln P + \frac{r}{r-1} \ln|(r-1)P - S| + C$. Here $r = 0.10$ and $S = 900$, so

$$\begin{aligned} t &= -\ln P + \frac{0.1}{-0.9} \ln|-0.9P - 900| + C = -\ln P - \frac{1}{9} \ln(|-1| |0.9P + 900|) \\ &= -\ln P - \frac{1}{9} \ln(0.9P + 900) + C \end{aligned}$$

When $t = 0$, $P = 10,000$, so $0 = -\ln 10,000 - \frac{1}{9} \ln(9900) + C$. Thus, $C = \ln 10,000 + \frac{1}{9} \ln 9900$ [≈ 10.2326], so our equation becomes

$$\begin{aligned} t &= \ln 10,000 - \ln P + \frac{1}{9} \ln 9900 - \frac{1}{9} \ln(0.9P + 900) = \ln \frac{10,000}{P} + \frac{1}{9} \ln \frac{9900}{0.9P + 900} \\ &= \ln \frac{10,000}{P} + \frac{1}{9} \ln \frac{1100}{0.1P + 100} = \ln \frac{10,000}{P} + \frac{1}{9} \ln \frac{11,000}{P + 1000} \end{aligned}$$

64. If we subtract and add $2x^2$, we get

$$\begin{aligned} x^4 + 1 &= x^4 + 2x^2 + 1 - 2x^2 = (x^2 + 1)^2 - 2x^2 = (x^2 + 1)^2 - (\sqrt{2}x)^2 \\ &= [(x^2 + 1) - \sqrt{2}x][(x^2 + 1) + \sqrt{2}x] = (x^2 - \sqrt{2}x + 1)(x^2 + \sqrt{2}x + 1) \end{aligned}$$

So we can decompose $\frac{1}{x^4 + 1} = \frac{Ax + B}{x^2 + \sqrt{2}x + 1} + \frac{Cx + D}{x^2 - \sqrt{2}x + 1} \Rightarrow$

$1 = (Ax + B)(x^2 - \sqrt{2}x + 1) + (Cx + D)(x^2 + \sqrt{2}x + 1)$. Setting the constant terms equal gives $B + D = 1$,

then from the coefficients of x^3 we get $A + C = 0$. Now from the coefficients of x we get

$A + C + (B - D)\sqrt{2} = 0 \Leftrightarrow [(1 - D) - D]\sqrt{2} = 0 \Rightarrow D = \frac{1}{2} \Rightarrow B = \frac{1}{2}$, and finally, from the coefficients of x^2 we get $\sqrt{2}(C - A) + B + D = 0 \Rightarrow C - A = -\frac{1}{\sqrt{2}} \Rightarrow C = -\frac{\sqrt{2}}{4}$ and $A = \frac{\sqrt{2}}{4}$.

So we rewrite the integrand, splitting the terms into forms which we know how to integrate:

$$\begin{aligned} \frac{1}{x^4 + 1} &= \frac{\frac{\sqrt{2}}{4}x + \frac{1}{2}}{x^2 + \sqrt{2}x + 1} + \frac{-\frac{\sqrt{2}}{4}x + \frac{1}{2}}{x^2 - \sqrt{2}x + 1} = \frac{1}{4\sqrt{2}} \left[\frac{2x + 2\sqrt{2}}{x^2 + \sqrt{2}x + 1} - \frac{2x - 2\sqrt{2}}{x^2 - \sqrt{2}x + 1} \right] \\ &= \frac{\sqrt{2}}{8} \left[\frac{2x + \sqrt{2}}{x^2 + \sqrt{2}x + 1} - \frac{2x - \sqrt{2}}{x^2 - \sqrt{2}x + 1} \right] + \frac{1}{4} \left[\frac{1}{\left(x + \frac{1}{\sqrt{2}}\right)^2 + \frac{1}{2}} + \frac{1}{\left(x - \frac{1}{\sqrt{2}}\right)^2 + \frac{1}{2}} \right] \end{aligned}$$

Now we integrate:

$$\int \frac{dx}{x^4 + 1} = \frac{\sqrt{2}}{8} \ln \left(\frac{x^2 + \sqrt{2}x + 1}{x^2 - \sqrt{2}x + 1} \right) + \frac{\sqrt{2}}{4} \left[\tan^{-1}(\sqrt{2}x + 1) + \tan^{-1}(\sqrt{2}x - 1) \right] + C.$$

65. (a) In Maple, we define $f(x)$, and then use `convert(f, parfrac, x)`; to obtain

$$f(x) = \frac{24,110/4879}{5x + 2} - \frac{668/323}{2x + 1} - \frac{9438/80,155}{3x - 7} + \frac{(22,098x + 48,935)/260,015}{x^2 + x + 5}.$$

In Mathematica, we use the command `Apart`, and in Derive, we use `Expand`.

$$\begin{aligned}
 \text{(b)} \quad \int f(x) dx &= \frac{24,110}{4879} \cdot \frac{1}{5} \ln|5x+2| - \frac{668}{323} \cdot \frac{1}{2} \ln|2x+1| - \frac{9438}{80,155} \cdot \frac{1}{3} \ln|3x-7| \\
 &\quad + \frac{1}{260,015} \int \frac{22,098(x + \frac{1}{2}) + 37,886}{(x + \frac{1}{2})^2 + \frac{19}{4}} dx + C \\
 &= \frac{24,110}{4879} \cdot \frac{1}{5} \ln|5x+2| - \frac{668}{323} \cdot \frac{1}{2} \ln|2x+1| - \frac{9438}{80,155} \cdot \frac{1}{3} \ln|3x-7| \\
 &\quad + \frac{1}{260,015} \left[22,098 \cdot \frac{1}{2} \ln(x^2 + x + 5) + 37,886 \cdot \sqrt{\frac{4}{19}} \tan^{-1} \left(\frac{1}{\sqrt{19/4}} (x + \frac{1}{2}) \right) \right] + C \\
 &= \frac{4822}{4879} \ln|5x+2| - \frac{334}{323} \ln|2x+1| - \frac{3146}{80,155} \ln|3x-7| + \frac{11,049}{260,015} \ln(x^2 + x + 5) \\
 &\quad + \frac{75,772}{260,015\sqrt{19}} \tan^{-1} \left[\frac{1}{\sqrt{19}} (2x+1) \right] + C
 \end{aligned}$$

Using a CAS, we get

$$\begin{aligned}
 &\frac{4822 \ln(5x+2)}{4879} - \frac{334 \ln(2x+1)}{323} - \frac{3146 \ln(3x-7)}{80,155} \\
 &\quad + \frac{11,049 \ln(x^2 + x + 5)}{260,015} + \frac{3988\sqrt{19}}{260,015} \tan^{-1} \left[\frac{\sqrt{19}}{19} (2x+1) \right]
 \end{aligned}$$

The main difference in this answer is that the absolute value signs and the constant of integration have been omitted. Also, the fractions have been reduced and the denominators rationalized.

66. (a) In Maple, we define $f(x)$, and then use `convert(f, parfrac, x)`; to get

$$f(x) = \frac{5828/1815}{(5x-2)^2} - \frac{59,096/19,965}{5x-2} + \frac{2(2843x+816)/3993}{2x^2+1} + \frac{(313x-251)/363}{(2x^2+1)^2}.$$

In Mathematica, we use the command `Apart`, and in Derive, we use `Expand`.

- (b) As we saw in Exercise 65, computer algebra systems omit the absolute value signs in $\int (1/y) dy = \ln|y|$. So we use the CAS to integrate the expression in part (a) and add the necessary absolute value signs and constant of integration to get

$$\begin{aligned}
 \int f(x) dx &= -\frac{5828}{9075(5x-2)} - \frac{59,096 \ln|5x-2|}{99,825} + \frac{2843 \ln(2x^2+1)}{7986} \\
 &\quad + \frac{503}{15,972} \sqrt{2} \tan^{-1}(\sqrt{2}x) - \frac{1}{2904} \frac{1004x+626}{2x^2+1} + C
 \end{aligned}$$

- (c) From the graph, we see that f goes from negative to positive at $x \approx -0.78$, then back to negative at $x \approx 0.8$, and finally back to positive at $x = 1$. Also, $\lim_{x \rightarrow 0.4} f(x) = \infty$. So we see (by the First Derivative Test) that $\int f(x) dx$ has minima at $x \approx -0.78$ and $x = 1$, and a maximum at $x \approx 0.80$, and that $\int f(x) dx$ is unbounded as $x \rightarrow 0.4$. Note also that just to the right of $x = 0.4$, f has large values, so $\int f(x) dx$ increases rapidly, but slows down as f drops toward 0. $\int f(x) dx$ decreases from about 0.8 to 1, then increases slowly since f stays small and positive.

67. There are only finitely many values of x where $Q(x) = 0$ (assuming that Q is not the zero polynomial). At all other values of x , $F(x)/Q(x) = G(x)/Q(x)$, so $F(x) = G(x)$. In other words, the values of F and G agree at all except perhaps finitely many values of x . By continuity of F and G , the polynomials F and G must agree at those values of x too.

More explicitly: if a is a value of x such that $Q(a) = 0$, then $Q(x) \neq 0$ for all x sufficiently close to a . Thus,

$$\begin{aligned} F(a) &= \lim_{x \rightarrow a} F(x) \quad [\text{by continuity of } F] = \lim_{x \rightarrow a} G(x) \quad [\text{whenever } Q(x) \neq 0] \\ &= G(a) \quad [\text{by continuity of } G] \end{aligned}$$

68. Let $f(x) = ax^2 + bx + c$. We calculate the partial fraction decomposition of $\frac{f(x)}{x^2(x+1)^3}$. Since $f(0) = 1$, we must have $c = 1$, so $\frac{f(x)}{x^2(x+1)^3} = \frac{ax^2 + bx + 1}{x^2(x+1)^3} = \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x+1} + \frac{D}{(x+1)^2} + \frac{E}{(x+1)^3}$. Now in order for the integral not to contain any logarithms (that is, in order for it to be a rational function), we must have $A = C = 0$, so $ax^2 + bx + 1 = B(x+1)^3 + Dx^2(x+1) + Ex^2$. Equating constant terms gives $B = 1$, then equating coefficients of x gives $3B = b \Rightarrow b = 3$. This is the quantity we are looking for, since $f'(0) = b$.

8.5 Strategy for Integration

- $\int \frac{\sin x + \sec x}{\tan x} dx = \int \left(\frac{\sin x}{\tan x} + \frac{\sec x}{\tan x} \right) dx = \int (\cos x + \csc x) dx = \sin x + \ln |\csc x - \cot x| + C$
- $\begin{aligned} \int \tan^3 \theta d\theta &= \int (\sec^2 \theta - 1) \tan \theta d\theta = \int \tan \theta \sec^2 \theta d\theta - \int \frac{\sin \theta}{\cos \theta} d\theta \\ &= \int u du + \int \frac{dv}{v} \quad \left[\begin{array}{l} u = \tan \theta, \quad v = \cos \theta, \\ du = \sec^2 \theta d\theta \quad dv = -\sin \theta d\theta \end{array} \right] \\ &= \frac{1}{2} u^2 + \ln |v| + C = \frac{1}{2} \tan^2 \theta + \ln |\cos \theta| + C \end{aligned}$
- $\begin{aligned} \int_0^2 \frac{2t}{(t-3)^2} dt &= \int_{-3}^{-1} \frac{2(u+3)}{u^2} du \quad [u = t-3, du = dt] = \int_{-3}^{-1} \left(\frac{2}{u} + \frac{6}{u^2} \right) du = \left[2 \ln |u| - \frac{6}{u} \right]_{-3}^{-1} \\ &= (2 \ln 1 + 6) - (2 \ln 3 + 2) = 4 - 2 \ln 3 \text{ or } 4 - \ln 9 \end{aligned}$
- Let $u = x^2$. Then $du = 2x dx \Rightarrow \int \frac{x dx}{\sqrt{3-x^4}} = \frac{1}{2} \int \frac{du}{\sqrt{3-u^2}} = \frac{1}{2} \sin^{-1} \frac{u}{\sqrt{3}} + C = \frac{1}{2} \sin^{-1} \frac{x^2}{\sqrt{3}} + C$.
- Let $u = \arctan y$. Then $du = \frac{dy}{1+y^2} \Rightarrow \int_{-1}^1 \frac{e^{\arctan y}}{1+y^2} dy = \int_{-\pi/4}^{\pi/4} e^u du = [e^u]_{-\pi/4}^{\pi/4} = e^{\pi/4} - e^{-\pi/4}$.
- $\begin{aligned} \int x \csc x \cot x dx &\quad \left[\begin{array}{l} u = x, \quad dv = \csc x \cot x dx, \\ du = dx \quad v = -\csc x \end{array} \right] = -x \csc x - \int (-\csc x) dx \\ &= -x \csc x + \ln |\csc x - \cot x| + C \end{aligned}$
- $\begin{aligned} \int_1^3 r^4 \ln r dr &\quad \left[\begin{array}{l} u = \ln r, \quad dv = r^4 dr, \\ du = \frac{dr}{r} \quad v = \frac{1}{5} r^5 \end{array} \right] = \left[\frac{1}{5} r^5 \ln r \right]_1^3 - \int_1^3 \frac{1}{5} r^4 dr = \frac{243}{5} \ln 3 - 0 - \left[\frac{1}{25} r^5 \right]_1^3 \\ &= \frac{243}{5} \ln 3 - \left(\frac{243}{25} - \frac{1}{25} \right) = \frac{243}{5} \ln 3 - \frac{242}{25} \end{aligned}$

8. $\frac{x-1}{x^2-4x-5} = \frac{x-1}{(x-5)(x+1)} = \frac{A}{x-5} + \frac{B}{x+1} \Rightarrow x-1 = A(x+1) + B(x-5)$. Setting $x = -1$ gives $-2 = -6B$, so $B = \frac{1}{3}$. Setting $x = 5$ gives $4 = 6A$, so $A = \frac{2}{3}$. Now

$$\begin{aligned}\int_0^4 \frac{x-1}{x^2-4x-5} dx &= \int_0^4 \left(\frac{2/3}{x-5} + \frac{1/3}{x+1} \right) dx = \left[\frac{2}{3} \ln|x-5| + \frac{1}{3} \ln|x+1| \right]_0^4 \\ &= \frac{2}{3} \ln 1 + \frac{1}{3} \ln 5 - \frac{2}{3} \ln 5 - \frac{1}{3} \ln 1 = -\frac{1}{3} \ln 5\end{aligned}$$

9. $\int \frac{x-1}{x^2-4x+5} dx = \int \frac{(x-2)+1}{(x-2)^2+1} dx = \int \left(\frac{u}{u^2+1} + \frac{1}{u^2+1} \right) du \quad [u = x-2, du = dx]$
 $= \frac{1}{2} \ln(u^2+1) + \tan^{-1} u + C = \frac{1}{2} \ln(x^2-4x+5) + \tan^{-1}(x-2) + C$

10. $\int \frac{x}{x^4+x^2+1} dx = \int \frac{\frac{1}{2} du}{u^2+u+1} \quad [u = x^2, du = 2x dx] = \frac{1}{2} \int \frac{du}{(u+\frac{1}{2})^2+\frac{3}{4}}$
 $= \frac{1}{2} \int \frac{\frac{\sqrt{3}}{2} dv}{\frac{3}{4}(v^2+1)} \quad [u+\frac{1}{2} = \frac{\sqrt{3}}{2}v, du = \frac{\sqrt{3}}{2} dv] = \frac{\sqrt{3}}{4} \cdot \frac{4}{3} \int \frac{dv}{v^2+1}$
 $= \frac{1}{\sqrt{3}} \tan^{-1} v + C = \frac{1}{\sqrt{3}} \tan^{-1} \left(\frac{2}{\sqrt{3}} \left(x^2 + \frac{1}{2} \right) \right) + C$

11. $\int \sin^3 \theta \cos^5 \theta d\theta = \int \cos^5 \theta \sin^2 \theta \sin \theta d\theta = -\int \cos^5 \theta (1-\cos^2 \theta)(-\sin \theta) d\theta$
 $= -\int u^5(1-u^2) du \quad \left[\begin{array}{l} u = \cos \theta, \\ du = -\sin \theta d\theta \end{array} \right]$
 $= \int (u^7 - u^5) du = \frac{1}{8} u^8 - \frac{1}{6} u^6 + C = \frac{1}{8} \cos^8 \theta - \frac{1}{6} \cos^6 \theta + C$

Another solution:

$$\begin{aligned}\int \sin^3 \theta \cos^5 \theta d\theta &= \int \sin^3 \theta (\cos^2 \theta)^2 \cos \theta d\theta = \int \sin^3 \theta (1-\sin^2 \theta)^2 \cos \theta d\theta \\ &= \int u^3(1-u^2)^2 du \quad \left[\begin{array}{l} u = \sin \theta, \\ du = \cos \theta d\theta \end{array} \right] = \int u^3(1-2u^2+u^4) du \\ &= \int (u^3 - 2u^5 + u^7) du = \frac{1}{4} u^4 - \frac{2}{6} u^6 + \frac{1}{8} u^8 + C = \frac{1}{4} \sin^4 \theta - \frac{1}{3} \sin^6 \theta + \frac{1}{8} \sin^8 \theta + C\end{aligned}$$

12. Let $u = \cos x$. Then $du = -\sin x dx \Rightarrow$

$$\int \sin x \cos(\cos x) dx = -\int \cos u du = -\sin u + C = -\sin(\cos x) + C.$$

13. Let $x = \sin \theta$, where $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Then $dx = \cos \theta d\theta$ and

$$\begin{aligned}(1-x^2)^{1/2} &= \cos \theta, \text{ so} \\ \int \frac{dx}{(1-x^2)^{3/2}} &= \int \frac{\cos \theta d\theta}{(\cos \theta)^3} = \int \sec^2 \theta d\theta \\ &= \tan \theta + C = \frac{x}{\sqrt{1-x^2}} + C\end{aligned}$$

14. Let $u = \ln x$. Then $du = dx/x \Rightarrow$

$$\begin{aligned}\int \frac{\sqrt{1+\ln x}}{x \ln x} dx &= \int \frac{\sqrt{1+u}}{u} du = \int \frac{v}{v^2-1} 2v dv \quad [\text{put } v = \sqrt{1+u}, u = v^2-1, du = 2v dv] \\ &= 2 \int \left(1 + \frac{1}{v^2-1} \right) dv = 2v + \ln \left| \frac{v-1}{v+1} \right| + C = 2\sqrt{1+\ln x} + \ln \left(\frac{\sqrt{1+\ln x}-1}{\sqrt{1+\ln x}+1} \right) + C\end{aligned}$$

15. Let $u = 1-x^2 \Rightarrow du = -2x dx$. Then

$$\int_0^{1/2} \frac{x}{\sqrt{1-x^2}} dx = -\frac{1}{2} \int_1^{3/4} \frac{1}{\sqrt{u}} du = \frac{1}{2} \int_{3/4}^1 u^{-1/2} du = \frac{1}{2} \left[2u^{1/2} \right]_{3/4}^1 = [\sqrt{u}]_{3/4}^1 = 1 - \frac{\sqrt{3}}{2}$$

$$\begin{aligned}
 16. \int_0^{\sqrt{2}/2} \frac{x^2}{\sqrt{1-x^2}} dx &= \int_0^{\pi/4} \frac{\sin^2 \theta}{\cos \theta} \cos \theta d\theta \quad [x = \sin \theta, dx = \cos \theta d\theta] \\
 &= \int_0^{\pi/4} \frac{1}{2}(1 - \cos 2\theta) d\theta = \frac{1}{2} \left[\theta - \frac{1}{2} \sin 2\theta \right]_0^{\pi/4} = \frac{1}{2} \left[\left(\frac{\pi}{4} - \frac{1}{2} \right) - (0 - 0) \right] = \frac{\pi}{8} - \frac{1}{4}
 \end{aligned}$$

$$\begin{aligned}
 17. \int x \sin^2 x dx &= \left[\begin{array}{l} u = x, \quad dv = \sin^2 x dx, \\ du = dx \quad v = \int \sin^2 x dx = \int \frac{1}{2}(1 - \cos 2x) dx = \frac{1}{2}x - \frac{1}{2} \sin x \cos x \end{array} \right] \\
 &= \frac{1}{2}x^2 - \frac{1}{2}x \sin x \cos x - \int \left(\frac{1}{2}x - \frac{1}{2} \sin x \cos x \right) dx \\
 &= \frac{1}{2}x^2 - \frac{1}{2}x \sin x \cos x - \frac{1}{4}x^2 + \frac{1}{4} \sin^2 x + C = \frac{1}{4}x^2 - \frac{1}{2}x \sin x \cos x + \frac{1}{4} \sin^2 x + C
 \end{aligned}$$

Note: $\int \sin x \cos x dx = \int s ds = \frac{1}{2}s^2 + C$ [where $s = \sin x$, $ds = \cos x dx$].

A slightly different method is to write $\int x \sin^2 x dx = \int x \cdot \frac{1}{2}(1 - \cos 2x) dx = \frac{1}{2} \int x dx - \frac{1}{2} \int x \cos 2x dx$. If we evaluate the second integral by parts, we arrive at the equivalent answer $\frac{1}{4}x^2 - \frac{1}{4}x \sin 2x - \frac{1}{8} \cos 2x + C$.

18. Let $u = e^{2t}$, $du = 2e^{2t} dt$. Then

$$\int \frac{e^{2t}}{1 + e^{4t}} dt = \int \frac{\frac{1}{2}(2e^{2t}) dt}{1 + (e^{2t})^2} = \int \frac{\frac{1}{2} du}{1 + u^2} = \frac{1}{2} \tan^{-1} u + C = \frac{1}{2} \tan^{-1}(e^{2t}) + C.$$

19. Let $u = e^x$. Then $\int e^{x+e^x} dx = \int e^{e^x} e^x dx = \int e^u du = e^u + C = e^{e^x} + C$.

20. Let $u = \sqrt[3]{x}$. Then $x = u^3 \Rightarrow \int e^{\sqrt[3]{x}} dx = \int e^u \cdot 3u^2 du$. Now use parts: let $w = u^2$, $dv = e^u du \Rightarrow$

$$dw = 2u du, v = e^u \Rightarrow 3 \int e^u u^2 du = 3(u^2 e^u - 2 \int u e^u du). \text{ Now use parts again with } W = u,$$

$$dV = e^u du \text{ to get } \int e^u 3u^2 du = e^u(3u^2 - 6u + 6) + C = 3e^{\sqrt[3]{x}}(x^{2/3} - 2\sqrt[3]{x} + 2) + C.$$

21. Integrate by parts three times, first with $u = t^3$, $dv = e^{-2t} dt$:

$$\begin{aligned}
 \int t^3 e^{-2t} dt &= -\frac{1}{2}t^3 e^{-2t} + \frac{1}{2} \int 3t^2 e^{-2t} dt = -\frac{1}{2}t^3 e^{-2t} - \frac{3}{4}t^2 e^{-2t} + \frac{1}{2} \int 3te^{-2t} dt \\
 &= -e^{-2t} \left[\frac{1}{2}t^3 + \frac{3}{4}t^2 \right] - \frac{3}{4}te^{-2t} + \frac{3}{4} \int e^{-2t} dt = -e^{-2t} \left[\frac{1}{2}t^3 + \frac{3}{4}t^2 + \frac{3}{4}t + \frac{3}{8} \right] + C \\
 &= -\frac{1}{8}e^{-2t}(4t^3 + 6t^2 + 6t + 3) + C
 \end{aligned}$$

22. Integrate by parts: $u = \sin^{-1} x$, $dv = x dx \Rightarrow du = (1/\sqrt{1-x^2}) dx$, $v = \frac{1}{2}x^2$, so

$$\begin{aligned}
 \int x \sin^{-1} x dx &= \frac{1}{2}x^2 \sin^{-1} x - \frac{1}{2} \int \frac{x^2 dx}{\sqrt{1-x^2}} = \frac{1}{2}x^2 \sin^{-1} x - \frac{1}{2} \int \frac{\sin^2 \theta \cos \theta d\theta}{\cos \theta} \quad \left[\begin{array}{l} \text{where } x = \sin \theta \\ \text{for } -\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2} \end{array} \right] \\
 &= \frac{1}{2}x^2 \sin^{-1} x - \frac{1}{4} \int (1 - \cos 2\theta) d\theta = \frac{1}{2}x^2 \sin^{-1} x - \frac{1}{4}(\theta - \sin \theta \cos \theta) + C \\
 &= \frac{1}{2}x^2 \sin^{-1} x - \frac{1}{4} \left[\sin^{-1} x - x\sqrt{1-x^2} \right] + C = \frac{1}{4} \left[(2x^2 - 1) \sin^{-1} x + x\sqrt{1-x^2} \right] + C
 \end{aligned}$$

23. Let $u = 1 + \sqrt{x}$. Then $x = (u-1)^2$, $dx = 2(u-1) du \Rightarrow$

$$\begin{aligned}
 \int_0^1 (1 + \sqrt{x})^8 dx &= \int_1^2 u^8 \cdot 2(u-1) du = 2 \int_1^2 (u^9 - u^8) du = \left[\frac{1}{5}u^{10} - 2 \cdot \frac{1}{9}u^9 \right]_1^2 \\
 &= \frac{1024}{5} - \frac{1024}{9} - \frac{1}{5} + \frac{2}{9} = \frac{4097}{45}
 \end{aligned}$$

24. Let $u = \ln(x^2 - 1)$, $dv = dx \Leftrightarrow du = \frac{2x}{x^2 - 1}$, $v = x$. Then

$$\begin{aligned}\int \ln(x^2 - 1) dx &= x \ln(x^2 - 1) - \int \frac{2x^2}{x^2 - 1} dx = x \ln(x^2 - 1) - \int \left[2 + \frac{2}{(x-1)(x+1)} \right] dx \\ &= x \ln(x^2 - 1) - \int \left[2 + \frac{1}{x-1} - \frac{1}{x+1} \right] dx \\ &= x \ln(x^2 - 1) - 2x - \ln|x-1| + \ln|x+1| + C\end{aligned}$$

25. $\frac{3x^2 - 2}{x^2 - 2x - 8} = 3 + \frac{6x + 22}{(x-4)(x+2)} = 3 + \frac{A}{x-4} + \frac{B}{x+2} \Rightarrow 6x + 22 = A(x+2) + B(x-4)$. Setting $x = 4$ gives $46 = 6A$, so $A = \frac{23}{3}$. Setting $x = -2$ gives $10 = -6B$, so $B = -\frac{5}{3}$. Now

$$\int \frac{3x^2 - 2}{x^2 - 2x - 8} dx = \int \left(3 + \frac{23/3}{x-4} - \frac{5/3}{x+2} \right) dx = 3x + \frac{23}{3} \ln|x-4| - \frac{5}{3} \ln|x+2| + C.$$

26. $\int \frac{3x^2 - 2}{x^3 - 2x - 8} dx = \int \frac{du}{u} \left[\begin{array}{l} u = x^3 - 2x - 8, \\ du = (3x^2 - 2) dx \end{array} \right] = \ln|u| + C = \ln|x^3 - 2x - 8| + C$

27. Let $u = \ln(\sin x)$. Then $du = \cot x dx \Rightarrow \int \cot x \ln(\sin x) dx = \int u du = \frac{1}{2}u^2 + C = \frac{1}{2}[\ln(\sin x)]^2 + C$.

28. $\int \sin \sqrt{at} dt = \int \sin u \cdot \frac{2}{a} u du \quad [u = \sqrt{at}, u^2 = at, 2u du = a dt] = \frac{2}{a} \int u \sin u du$
 $= \frac{2}{a} [-u \cos u + \sin u] + C \quad [\text{integration by parts}] = -\frac{2}{a} \sqrt{at} \cos \sqrt{at} + \frac{2}{a} \sin \sqrt{at} + C$
 $= -2\sqrt{\frac{t}{a}} \cos \sqrt{at} + \frac{2}{a} \sin \sqrt{at} + C$

29. $\int_0^5 \frac{3w-1}{w+2} dw = \int_0^5 \left(3 - \frac{7}{w+2} \right) dw = [3w - 7 \ln|w+2|]_0^5$
 $= 15 - 7 \ln 7 + 7 \ln 2 = 15 + 7(\ln 2 - \ln 7) = 15 + 7 \ln \frac{2}{7}$

30. $x^2 - 4x < 0$ on $[0, 4]$, so

$$\begin{aligned}\int_{-2}^2 |x^2 - 4x| dx &= \int_{-2}^0 (x^2 - 4x) dx + \int_0^2 (4x - x^2) dx = \left[\frac{1}{3}x^3 - 2x^2 \right]_{-2}^0 + \left[2x^2 - \frac{1}{3}x^3 \right]_0^2 \\ &= 0 - \left(-\frac{8}{3} - 8 \right) + \left(8 - \frac{8}{3} \right) - 0 = 16\end{aligned}$$

31. As in Example 5,

$$\begin{aligned}\int \sqrt{\frac{1+x}{1-x}} dx &= \int \frac{\sqrt{1+x}}{\sqrt{1-x}} \cdot \frac{\sqrt{1+x}}{\sqrt{1+x}} dx = \int \frac{1+x}{\sqrt{1-x^2}} dx = \int \frac{dx}{\sqrt{1-x^2}} + \int \frac{x dx}{\sqrt{1-x^2}} \\ &= \sin^{-1} x - \sqrt{1-x^2} + C\end{aligned}$$

Another method: Substitute $u = \sqrt{(1+x)/(1-x)}$.

32. $\int \frac{\sqrt{2x-1}}{2x+3} dx = \int \frac{u \cdot u du}{u^2 + 4} \left[\begin{array}{l} u = \sqrt{2x-1}, 2x+3 = u^2 + 4, \\ u^2 = 2x-1, u du = dx \end{array} \right] = \int \left(1 - \frac{4}{u^2 + 4} \right) du$
 $= u - 4 \cdot \frac{1}{2} \tan^{-1} \left(\frac{1}{2}u \right) + C = \sqrt{2x-1} - 2 \tan^{-1} \left(\frac{1}{2}\sqrt{2x-1} \right) + C$

33. $3 - 2x - x^2 = -(x^2 + 2x + 1) + 4 = 4 - (x + 1)^2$. Let

$x + 1 = 2 \sin \theta$, where $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. Then $dx = 2 \cos \theta d\theta$ and

$$\int \sqrt{3 - 2x - x^2} dx = \int \sqrt{4 - (x + 1)^2} dx = \int \sqrt{4 - 4 \sin^2 \theta} 2 \cos \theta d\theta$$

$$= 4 \int \cos^2 \theta d\theta = 2 \int (1 + \cos 2\theta) d\theta$$

$$= 2\theta + \sin 2\theta + C = 2\theta + 2 \sin \theta \cos \theta + C$$

$$= 2 \sin^{-1} \left(\frac{x+1}{2} \right) + 2 \cdot \frac{x+1}{2} \cdot \frac{\sqrt{3-2x-x^2}}{2} + C$$

$$= 2 \sin^{-1} \left(\frac{x+1}{2} \right) + \frac{x+1}{2} \sqrt{3-2x-x^2} + C$$

34.
$$\int_{\pi/4}^{\pi/2} \frac{1 + 4 \cot x}{4 - \cot x} dx = \int_{\pi/4}^{\pi/2} \left[\frac{(1 + 4 \cos x / \sin x)}{(4 - \cos x / \sin x)} \cdot \frac{\sin x}{\sin x} \right] dx = \int_{\pi/4}^{\pi/2} \frac{\sin x + 4 \cos x}{4 \sin x - \cos x} dx$$

$$= \int_{3/\sqrt{2}}^4 \frac{1}{u} du \quad \left[\begin{array}{l} u = 4 \sin x - \cos x, \\ du = (4 \cos x + \sin x) dx \end{array} \right] = \left[\ln |u| \right]_{3/\sqrt{2}}^4$$

$$= \ln 4 - \ln \frac{3}{\sqrt{2}} = \ln \frac{4}{3/\sqrt{2}} = \ln \left(\frac{4}{3} \sqrt{2} \right)$$

35. Because $f(x) = x^8 \sin x$ is the product of an even function and an odd function, it is odd. Therefore,

$$\int_{-1}^1 x^8 \sin x dx = 0 \quad [\text{by (5.5.6)(b)}].$$

36. $\sin 4x \cos 3x = \frac{1}{2}(\sin x + \sin 7x)$ by Formula 8.2.2(a), so

$$\int \sin 4x \cos 3x dx = \frac{1}{2} \int (\sin x + \sin 7x) dx = \frac{1}{2} \left[-\cos x - \frac{1}{7} \cos 7x \right] + C = -\frac{1}{2} \cos x - \frac{1}{14} \cos 7x + C.$$

37.
$$\int_0^{\pi/4} \cos^2 \theta \tan^2 \theta d\theta = \int_0^{\pi/4} \sin^2 \theta d\theta = \int_0^{\pi/4} \frac{1}{2} (1 - \cos 2\theta) d\theta = \left[\frac{1}{2} \theta - \frac{1}{4} \sin 2\theta \right]_0^{\pi/4}$$

$$= \left(\frac{\pi}{8} - \frac{1}{4} \right) - (0 - 0) = \frac{\pi}{8} - \frac{1}{4}$$

38.
$$\int_0^{\pi/4} \tan^5 \theta \sec^3 \theta d\theta = \int_0^{\pi/4} (\tan^2 \theta)^2 \sec^2 \theta \cdot \sec \theta \tan \theta d\theta = \int_1^{\sqrt{2}} (u^2 - 1)^2 u^2 du \quad \left[\begin{array}{l} u = \sec \theta \\ du = \sec \theta \tan \theta d\theta \end{array} \right]$$

$$= \int_1^{\sqrt{2}} (u^6 - 2u^4 + u^2) du = \left[\frac{1}{7} u^7 - \frac{2}{5} u^5 + \frac{1}{3} u^3 \right]_1^{\sqrt{2}}$$

$$= \left(\frac{8}{7} \sqrt{2} - \frac{8}{5} \sqrt{2} + \frac{2}{3} \sqrt{2} \right) - \left(\frac{1}{7} - \frac{2}{5} + \frac{1}{3} \right) = \frac{22}{105} \sqrt{2} - \frac{8}{105} = \frac{2}{105} (11 \sqrt{2} - 4)$$

39. Let $u = 1 - x^2$. Then $du = -2x dx \Rightarrow$

$$\int \frac{x dx}{1 - x^2 + \sqrt{1 - x^2}} = -\frac{1}{2} \int \frac{du}{u + \sqrt{u}} = -\int \frac{v dv}{v^2 + v} \quad [v = \sqrt{u}, u = v^2, du = 2v dv]$$

$$= -\int \frac{dv}{v+1} = -\ln |v+1| + C = -\ln (\sqrt{1-x^2} + 1) + C$$

40. $4y^2 - 4y - 3 = (2y - 1)^2 - 2^2$, so let $u = 2y - 1 \Rightarrow du = 2 dy$. Thus,

$$\int \frac{dy}{\sqrt{4y^2 - 4y - 3}} = \int \frac{dy}{\sqrt{(2y - 1)^2 - 2^2}} = \frac{1}{2} \int \frac{du}{\sqrt{u^2 - 2^2}}$$

$$= \frac{1}{2} \ln \left| u + \sqrt{u^2 - 2^2} \right| \quad [\text{by Formula 20 in the table in this section}]$$

$$= \frac{1}{2} \ln \left| 2y - 1 + \sqrt{4y^2 - 4y - 3} \right| + C$$

41. Let $u = \theta$, $dv = \tan^2 \theta d\theta = (\sec^2 \theta - 1) d\theta \Rightarrow du = d\theta$ and $v = \tan \theta - \theta$. So

$$\begin{aligned}\int \theta \tan^2 \theta d\theta &= \theta(\tan \theta - \theta) - \int (\tan \theta - \theta) d\theta = \theta \tan \theta - \theta^2 - \ln |\sec \theta| + \frac{1}{2} \theta^2 + C \\ &= \theta \tan \theta - \frac{1}{2} \theta^2 - \ln |\sec \theta| + C\end{aligned}$$

42. Integrate by parts with $u = \tan^{-1} x$, $dv = x^2 dx \Rightarrow du = dx/(1+x^2)$, $v = \frac{1}{3}x^3$:

$$\begin{aligned}\int x^2 \tan^{-1} x dx &= \frac{1}{3}x^3 \tan^{-1} x - \int \frac{x^3}{3} \frac{dx}{1+x^2} = \frac{1}{3}x^3 \tan^{-1} x - \frac{1}{3} \int \left[x - \frac{x}{x^2+1} \right] dx \\ &= \frac{1}{3}x^3 \tan^{-1} x - \frac{1}{6}x^2 + \frac{1}{6} \ln(x^2+1) + C\end{aligned}$$

43. Let $u = 1 + e^x$, so that $du = e^x dx$. Then

$$\int e^x \sqrt{1+e^x} dx = \int u^{1/2} du = \frac{2}{3} u^{3/2} + C = \frac{2}{3} (1+e^x)^{3/2} + C.$$

Or: Let $u = \sqrt{1+e^x}$, so that $u^2 = 1+e^x$ and $2u du = e^x dx$. Then

$$\int e^x \sqrt{1+e^x} dx = \int u \cdot 2u du = \int 2u^2 du = \frac{2}{3} u^3 + C = \frac{2}{3} (1+e^x)^{3/2} + C.$$

44. Let $u = \sqrt{1+e^x}$. Then $u^2 = 1+e^x$, $2u du = e^x dx = (u^2-1) dx$, and $dx = \frac{2u}{u^2-1} du$, so

$$\begin{aligned}\int \sqrt{1+e^x} dx &= \int u \cdot \frac{2u}{u^2-1} du = \int \frac{2u^2}{u^2-1} du = \int \left(2 + \frac{2}{u^2-1} \right) du = \int \left(2 + \frac{1}{u-1} - \frac{1}{u+1} \right) du \\ &= 2u + \ln|u-1| - \ln|u+1| + C = 2\sqrt{1+e^x} + \ln(\sqrt{1+e^x}-1) - \ln(\sqrt{1+e^x}+1) + C\end{aligned}$$

45. Let $t = x^3$. Then $dt = 3x^2 dx \Rightarrow I = \int x^5 e^{-x^3} dx = \frac{1}{3} \int t e^{-t} dt$. Now integrate by parts with $u = t$,

$$dv = e^{-t} dt: I = -\frac{1}{3} t e^{-t} + \frac{1}{3} \int e^{-t} dt = -\frac{1}{3} t e^{-t} - \frac{1}{3} e^{-t} + C = -\frac{1}{3} e^{-x^3} (x^3 + 1) + C.$$

46. Let $u = e^x$. Then $x = \ln u$, $dx = du/u \Rightarrow$

$$\begin{aligned}\int \frac{1+e^x}{1-e^x} dx &= \int \frac{(1+u) du}{(1-u)u} = - \int \frac{(u+1) du}{(u-1)u} = - \int \left(\frac{2}{u-1} - \frac{1}{u} \right) du \\ &= \ln|u| - 2 \ln|u-1| + C = \ln e^x - 2 \ln|e^x-1| + C = x - 2 \ln|e^x-1| + C\end{aligned}$$

47. $\int \frac{x+a}{x^2+a^2} dx = \frac{1}{2} \int \frac{2x dx}{x^2+a^2} + a \int \frac{dx}{x^2+a^2} = \frac{1}{2} \ln(x^2+a^2) + a \cdot \frac{1}{a} \tan^{-1} \left(\frac{x}{a} \right) + C$
 $= \ln \sqrt{x^2+a^2} + \tan^{-1}(x/a) + C$

48. Let $u = x^2$. Then $du = 2x dx \Rightarrow$

$$\int \frac{x dx}{x^4 - a^4} = \int \frac{\frac{1}{2} du}{u^2 - (a^2)^2} = \frac{1}{4a^2} \ln \left| \frac{u-a^2}{u+a^2} \right| + C = \frac{1}{4a^2} \ln \left| \frac{x^2-a^2}{x^2+a^2} \right| + C.$$

49. Let $u = \sqrt{4x+1} \Rightarrow u^2 = 4x+1 \Rightarrow 2u du = 4 dx \Rightarrow dx = \frac{1}{2} u du$. So

$$\begin{aligned}\int \frac{1}{x \sqrt{4x+1}} dx &= \int \frac{\frac{1}{2} u du}{\frac{1}{4}(u^2-1)u} = 2 \int \frac{du}{u^2-1} = 2 \left(\frac{1}{2} \right) \ln \left| \frac{u-1}{u+1} \right| + C \quad [\text{by Formula 19}] \\ &= \ln \left| \frac{\sqrt{4x+1}-1}{\sqrt{4x+1}+1} \right| + C\end{aligned}$$

50. As in Exercise 49, let $u = \sqrt{4x+1}$. Then $\int \frac{dx}{x^2\sqrt{4x+1}} = \int \frac{\frac{1}{2}u \, du}{\left[\frac{1}{4}(u^2-1)\right]^2 u} = 8 \int \frac{du}{(u^2-1)^2}$. Now

$$\frac{1}{(u^2-1)^2} = \frac{1}{(u+1)^2(u-1)^2} = \frac{A}{u+1} + \frac{B}{(u+1)^2} + \frac{C}{u-1} + \frac{D}{(u-1)^2} \Rightarrow$$

$$1 = A(u+1)(u-1)^2 + B(u-1)^2 + C(u-1)(u+1)^2 + D(u+1)^2. \quad u=1 \Rightarrow D = \frac{1}{4}, u=-1 \Rightarrow B = \frac{1}{4}. \text{ Equating coefficients of } u^3 \text{ gives } A+C=0, \text{ and equating coefficients of } 1 \text{ gives } 1 = A+B-C+D \Rightarrow 1 = A + \frac{1}{4} - C + \frac{1}{4} \Rightarrow \frac{1}{2} = A - C. \text{ So } A = \frac{1}{4} \text{ and } C = -\frac{1}{4}. \text{ Therefore,}$$

$$\begin{aligned}\int \frac{dx}{x^2\sqrt{4x+1}} &= 8 \int \left[\frac{1/4}{u+1} + \frac{1/4}{(u+1)^2} + \frac{-1/4}{u-1} + \frac{1/4}{(u-1)^2} \right] du \\ &= \int \left[\frac{2}{u+1} + 2(u+1)^{-2} - \frac{2}{u-1} + 2(u-1)^{-2} \right] du \\ &= 2 \ln|u+1| - \frac{2}{u+1} - 2 \ln|u-1| - \frac{2}{u-1} + C \\ &= 2 \ln(\sqrt{4x+1}+1) - \frac{2}{\sqrt{4x+1}+1} - 2 \ln|\sqrt{4x+1}-1| - \frac{2}{\sqrt{4x+1}-1} + C\end{aligned}$$

51. Let $2x = \tan \theta \Rightarrow x = \frac{1}{2} \tan \theta, dx = \frac{1}{2} \sec^2 \theta d\theta, \sqrt{4x^2 + 1} = \sec \theta$, so

$$\begin{aligned}\int \frac{dx}{x\sqrt{4x^2+1}} &= \int \frac{\frac{1}{2}\sec^2\theta d\theta}{\frac{1}{2}\tan\theta\sec\theta} = \int \frac{\sec\theta}{\tan\theta} d\theta = \int \csc\theta d\theta \\ &= -\ln|\csc\theta + \cot\theta| + C \quad [\text{or } \ln|\csc\theta - \cot\theta| + C] \\ &= -\ln\left|\frac{\sqrt{4x^2+1}}{2x} + \frac{1}{2x}\right| + C \quad \left[\text{or } \ln\left|\frac{\sqrt{4x^2+1}}{2x} - \frac{1}{2x}\right| + C\right]\end{aligned}$$

52. Let $u = x^2$. Then $du = 2x \, dx \Rightarrow$

$$\begin{aligned}\int \frac{dx}{x(x^4+1)} &= \int \frac{x \, dx}{x^2(x^4+1)} = \frac{1}{2} \int \frac{du}{u(u^2+1)} = \frac{1}{2} \int \left[\frac{1}{u} - \frac{u}{u^2+1} \right] du = \frac{1}{2} \ln|u| - \frac{1}{4} \ln(u^2+1) + C \\ &= \frac{1}{2} \ln(x^2) - \frac{1}{4} \ln(x^4+1) + C = \frac{1}{4} [\ln(x^4) - \ln(x^4+1)] + C = \frac{1}{4} \ln\left(\frac{x^4}{x^4+1}\right) + C\end{aligned}$$

Or: Write $I = \int \frac{x^3 dx}{x^4(x^4 + 1)}$ and let $u = x^4$.

53. $\int x^2 \sinh(mx) dx = \frac{1}{m} x^2 \cosh(mx) - \frac{2}{m} \int x \cosh(mx) dx$ $\left[\begin{array}{ll} u = x^2, & dv = \sinh(mx) dx, \\ du = 2x dx & v = \frac{1}{m} \cosh(mx) \end{array} \right]$

$= \frac{1}{m} x^2 \cosh(mx) - \frac{2}{m} \left(\frac{1}{m} x \sinh(mx) - \frac{1}{m} \int \sinh(mx) dx \right)$ $\left[\begin{array}{ll} U = x, & dV = \cosh(mx) dx, \\ dU = dx & V = \frac{1}{m} \sinh(mx) \end{array} \right]$

$= \frac{1}{m} x^2 \cosh(mx) - \frac{2}{m^2} x \sinh(mx) + \frac{2}{m^3} \cosh(mx) + C$

54. $\int (x + \sin x)^2 dx = \int (x^2 + 2x \sin x + \sin^2 x) dx = \frac{1}{3}x^3 + 2(\sin x - x \cos x) + \frac{1}{2}(x - \sin x \cos x) + C$
 $= \frac{1}{3}x^3 + \frac{1}{2}x + 2 \sin x - \frac{1}{2} \sin x \cos x - 2x \cos x + C$

55. Let $u = \sqrt{x+1}$. Then $x = u^2 - 1 \Rightarrow$

$$\begin{aligned}\int \frac{dx}{x+4+4\sqrt{x+1}} &= \int \frac{2u du}{u^2+3+4u} = \int \left[\frac{-1}{u+1} + \frac{3}{u+3} \right] du \\ &= 3 \ln|u+3| - \ln|u+1| + C = 3 \ln(\sqrt{x+1}+3) - \ln(\sqrt{x+1}+1) + C\end{aligned}$$

56. Let $t = \sqrt{x^2-1}$. Then $dt = (x/\sqrt{x^2-1}) dx$, $x^2-1 = t^2$, $x = \sqrt{t^2+1}$, so

$$I = \int \frac{x \ln x}{\sqrt{x^2-1}} dx = \int \ln \sqrt{t^2+1} dt = \frac{1}{2} \int \ln(t^2+1) dt. \text{ Now use parts with } u = \ln(t^2+1), dv = dt:$$

$$\begin{aligned}I &= \frac{1}{2} t \ln(t^2+1) - \int \frac{t^2}{t^2+1} dt = \frac{1}{2} t \ln(t^2+1) - \int \left[1 - \frac{1}{t^2+1} \right] dt \\ &= \frac{1}{2} t \ln(t^2+1) - t + \tan^{-1} t + C = \sqrt{x^2-1} \ln x - \sqrt{x^2-1} + \tan^{-1} \sqrt{x^2-1} + C\end{aligned}$$

Another method: First integrate by parts with $u = \ln x$, $dv = (x/\sqrt{x^2-1}) dx$ and then use substitution ($x = \sec \theta$ or $u = \sqrt{x^2-1}$).

57. Let $u = \sqrt[3]{x+c}$. Then $x = u^3 - c \Rightarrow$

$$\begin{aligned}\int x \sqrt[3]{x+c} dx &= \int (u^3 - c)u \cdot 3u^2 du = 3 \int (u^6 - cu^3) du = \frac{3}{7} u^7 - \frac{3}{4} cu^4 + C \\ &= \frac{3}{7} (x+c)^{7/3} - \frac{3}{4} c(x+c)^{4/3} + C\end{aligned}$$

58. Integrate by parts with $u = \ln(1+x)$, $dv = x^2 dx \Rightarrow du = dx/(1+x)$, $v = \frac{1}{3}x^3$:

$$\begin{aligned}\int x^2 \ln(1+x) dx &= \frac{1}{3} x^3 \ln(1+x) - \int \frac{x^3 dx}{3(1+x)} = \frac{1}{3} x^3 \ln(1+x) - \frac{1}{3} \int \left(x^2 - x + 1 - \frac{1}{x+1} \right) dx \\ &= \frac{1}{3} x^3 \ln(1+x) - \frac{1}{9} x^3 + \frac{1}{6} x^2 - \frac{1}{3} x + \frac{1}{3} \ln(1+x) + C\end{aligned}$$

59. Let $u = e^x$. Then $x = \ln u$, $dx = du/u \Rightarrow$

$$\begin{aligned}\int \frac{dx}{e^{3x} - e^x} &= \int \frac{du/u}{u^3 - u} = \int \frac{du}{(u-1)u^2(u+1)} = \int \left[\frac{1/2}{u-1} - \frac{1}{u^2} - \frac{1/2}{u+1} \right] du \\ &= \frac{1}{u} + \frac{1}{2} \ln \left| \frac{u-1}{u+1} \right| + C = e^{-x} + \frac{1}{2} \ln \left| \frac{e^x-1}{e^x+1} \right| + C\end{aligned}$$

60. Let $u = \sqrt[3]{x}$. Then $x = u^3$, $dx = 3u^2 du \Rightarrow$

$$\int \frac{dx}{x + \sqrt[3]{x}} = \int \frac{3u^2 du}{u^3 + u} = \frac{3}{2} \int \frac{2u du}{u^2 + 1} = \frac{3}{2} \ln(u^2 + 1) + C = \frac{3}{2} \ln(x^{2/3} + 1) + C.$$

61. Let $u = x^5$. Then $du = 5x^4 dx \Rightarrow$

$$\int \frac{x^4 dx}{x^{10} + 16} = \int \frac{\frac{1}{5} du}{u^2 + 16} = \frac{1}{5} \cdot \frac{1}{4} \tan^{-1} \left(\frac{1}{4} u \right) + C = \frac{1}{20} \tan^{-1} \left(\frac{1}{4} x^5 \right) + C.$$

62. Let $u = x+1$. Then $du = dx \Rightarrow$

$$\begin{aligned}\int \frac{x^3}{(x+1)^{10}} dx &= \int \frac{(u-1)^3}{u^{10}} du = \int (u^{-7} - 3u^{-8} + 3u^{-9} - u^{-10}) du \\ &= -\frac{1}{6} u^{-6} + \frac{3}{7} u^{-7} - \frac{3}{8} u^{-8} + \frac{1}{9} u^{-9} + C \\ &= (x+1)^{-9} \left[-\frac{1}{6} (x+1)^3 + \frac{3}{7} (x+1)^2 - \frac{3}{8} (x+1) + \frac{1}{9} \right] + C\end{aligned}$$

63. Let $y = \sqrt{x}$ so that $dy = \frac{1}{2\sqrt{x}} dx \Rightarrow dx = 2\sqrt{x} dy = 2y dy$. Then

$$\begin{aligned}\int \sqrt{x} e^{\sqrt{x}} dx &= \int y e^y (2y dy) = \int 2y^2 e^y dy \quad \left[\begin{array}{l} u = 2y^2, \quad dv = e^y dy, \\ du = 4y dy \quad v = e^y \end{array} \right] \\ &= 2y^2 e^y - \int 4y e^y dy \quad \left[\begin{array}{l} U = 4y, \quad dV = e^y dy, \\ dU = 4 dy \quad V = e^y \end{array} \right] \\ &= 2y^2 e^y - (4y e^y - \int 4e^y dy) = 2y^2 e^y - 4y e^y + 4e^y + C \\ &= 2(y^2 - 2y + 2)e^y + C = 2(x - 2\sqrt{x} + 2)e^{\sqrt{x}} + C\end{aligned}$$

64. Let $u = \tan x$. Then

$$\begin{aligned}\int_{\pi/4}^{\pi/3} \frac{\ln(\tan x) dx}{\sin x \cos x} &= \int_{\pi/4}^{\pi/3} \frac{\ln(\tan x)}{\tan x} \sec^2 x dx = \int_1^{\sqrt{3}} \frac{\ln u}{u} du \\ &= \left[\frac{1}{2} (\ln u)^2 \right]_1^{\sqrt{3}} = \frac{1}{2} (\ln \sqrt{3})^2 = \frac{1}{8} (\ln 3)^2\end{aligned}$$

65.
$$\int \frac{dx}{\sqrt{x+1} + \sqrt{x}} = \int \left(\frac{1}{\sqrt{x+1} + \sqrt{x}} \cdot \frac{\sqrt{x+1} - \sqrt{x}}{\sqrt{x+1} - \sqrt{x}} \right) dx = \int (\sqrt{x+1} - \sqrt{x}) dx$$

$$= \frac{2}{3} \left[(x+1)^{3/2} - x^{3/2} \right] + C$$

66.
$$\int \frac{u^3 + 1}{u^3 - u^2} du = \int \left[1 + \frac{u^2 + 1}{(u-1)u^2} \right] du = u + \int \left[\frac{2}{u-1} - \frac{1}{u} - \frac{1}{u^2} \right] du = u + 2 \ln |u-1| - \ln |u| + \frac{1}{u} + C.$$

Thus,

$$\begin{aligned}\int_2^3 \frac{u^3 + 1}{u^3 - u^2} du &= \left[u + 2 \ln(u-1) - \ln u + \frac{1}{u} \right]_2^3 = \left(3 + 2 \ln 2 - \ln 3 + \frac{1}{3} \right) - \left(2 + 2 \ln 1 - \ln 2 + \frac{1}{2} \right) \\ &= 1 + 3 \ln 2 - \ln 3 - \frac{1}{6} = \frac{5}{6} + \ln \frac{8}{3}\end{aligned}$$

67. Let $u = \sqrt{t}$. Then $du = dt/(2\sqrt{t}) \Rightarrow$

$$\begin{aligned}\int_1^3 \frac{\arctan \sqrt{t}}{\sqrt{t}} dt &= \int_1^{\sqrt{3}} \tan^{-1} u (2 du) = 2 \left[u \tan^{-1} u - \frac{1}{2} \ln(1+u^2) \right]_1^{\sqrt{3}} \quad [\text{Example 5 in Section 8.1}] \\ &= 2 \left[\left(\sqrt{3} \tan^{-1} \sqrt{3} - \frac{1}{2} \ln 4 \right) - \left(\tan^{-1} 1 - \frac{1}{2} \ln 2 \right) \right] \\ &= 2 \left[\left(\sqrt{3} \cdot \frac{\pi}{3} - \ln 2 \right) - \left(\frac{\pi}{4} - \frac{1}{2} \ln 2 \right) \right] = \frac{2}{3} \sqrt{3} \pi - \frac{1}{2} \pi - \ln 2\end{aligned}$$

68. Let $u = e^x$. Then $x = \ln u$, $dx = du/u \Rightarrow$

$$\begin{aligned}\int \frac{dx}{1+2e^x - e^{-x}} &= \int \frac{du/u}{1+2u-1/u} = \int \frac{du}{2u^2+u-1} = \int \left[\frac{2/3}{2u-1} - \frac{1/3}{u+1} \right] du \\ &= \frac{1}{3} \ln |2u-1| - \frac{1}{3} \ln |u+1| + C = \frac{1}{3} \ln |(2e^x-1)/(e^x+1)| + C\end{aligned}$$

69. Let $u = e^x$. Then $x = \ln u$, $dx = du/u \Rightarrow$

$$\begin{aligned}\int \frac{e^{2x}}{1+e^x} dx &= \int \frac{u^2}{1+u} \frac{du}{u} = \int \frac{u}{1+u} du = \int \left(1 - \frac{1}{1+u} \right) du \\ &= u - \ln |1+u| + C = e^x - \ln(1+e^x) + C\end{aligned}$$

70. Use parts with $u = \ln(x+1)$, $dv = dx/x^2$:

$$\begin{aligned}\int \frac{\ln(x+1)}{x^2} dx &= -\frac{1}{x} \ln(x+1) + \int \frac{dx}{x(x+1)} = -\frac{1}{x} \ln(x+1) + \int \left[\frac{1}{x} - \frac{1}{x+1} \right] dx \\ &= -\frac{1}{x} \ln(x+1) + \ln |x| - \ln(x+1) + C = -\left(1 + \frac{1}{x}\right) \ln(x+1) + \ln |x| + C\end{aligned}$$

$$71. \frac{x}{x^4 + 4x^2 + 3} = \frac{x}{(x^2 + 3)(x^2 + 1)} = \frac{Ax + B}{x^2 + 3} + \frac{Cx + D}{x^2 + 1} \Rightarrow$$

$$\begin{aligned} x &= (Ax + B)(x^2 + 1) + (Cx + D)(x^2 + 3) = (Ax^3 + Bx^2 + Ax + B) + (Cx^3 + Dx^2 + 3Cx + 3D) \\ &= (A + C)x^3 + (B + D)x^2 + (A + 3C)x + (B + 3D) \Rightarrow \end{aligned}$$

$$A + C = 0, B + D = 0, A + 3C = 1, B + 3D = 0 \Rightarrow A = -\frac{1}{2}, C = \frac{1}{2}, B = 0, D = 0. \text{ Thus,}$$

$$\begin{aligned} \int \frac{x}{x^4 + 4x^2 + 3} dx &= \int \left(\frac{-\frac{1}{2}x}{x^2 + 3} + \frac{\frac{1}{2}x}{x^2 + 1} \right) dx \\ &= -\frac{1}{4} \ln(x^2 + 3) + \frac{1}{4} \ln(x^2 + 1) + C \quad \text{or} \quad \frac{1}{4} \ln \left(\frac{x^2 + 1}{x^2 + 3} \right) + C \end{aligned}$$

$$72. \text{ Let } u = \sqrt[6]{t}. \text{ Then } t = u^6, dt = 6u^5 du \Rightarrow$$

$$\begin{aligned} \int \frac{\sqrt{t} dt}{1 + \sqrt[3]{t}} &= \int \frac{u^3 \cdot 6u^5 du}{1 + u^2} = 6 \int \frac{u^8}{u^2 + 1} du = 6 \int \left(u^6 - u^4 + u^2 - 1 + \frac{1}{u^2 + 1} \right) du \\ &= 6 \left(\frac{1}{7} u^7 - \frac{1}{5} u^5 + \frac{1}{3} u^3 - u + \tan^{-1} u \right) + C \\ &= 6 \left(\frac{1}{7} t^{7/6} - \frac{1}{5} t^{5/6} + \frac{1}{3} t^{1/2} - t^{1/6} + \tan^{-1} t^{1/6} \right) + C \end{aligned}$$

$$73. \frac{1}{(x-2)(x^2+4)} = \frac{A}{x-2} + \frac{Bx+C}{x^2+4} \Rightarrow$$

$$1 = A(x^2 + 4) + (Bx + C)(x - 2) = (A + B)x^2 + (C - 2B)x + (4A - 2C). \text{ So } 0 = A + B = C - 2B,$$

$$1 = 4A - 2C. \text{ Setting } x = 2 \text{ gives } A = \frac{1}{8} \Rightarrow B = -\frac{1}{8} \text{ and } C = -\frac{1}{4}. \text{ So}$$

$$\begin{aligned} \int \frac{1}{(x-2)(x^2+4)} dx &= \int \left(\frac{\frac{1}{8}}{x-2} + \frac{-\frac{1}{8}x - \frac{1}{4}}{x^2+4} \right) dx = \frac{1}{8} \int \frac{dx}{x-2} - \frac{1}{16} \int \frac{2x dx}{x^2+4} - \frac{1}{4} \int \frac{dx}{x^2+4} \\ &= \frac{1}{8} \ln|x-2| - \frac{1}{16} \ln(x^2+4) - \frac{1}{8} \tan^{-1}(x/2) + C \end{aligned}$$

$$74. \text{ Let } u = e^x. \text{ Then } x = \ln u, dx = du/u \Rightarrow$$

$$\int \frac{dx}{e^x - e^{-x}} = \int \frac{e^x dx}{e^{2x} - 1} = \int \frac{u}{u^2 - 1} \frac{du}{u} = \int \frac{du}{u^2 - 1} = \frac{1}{2} \ln \left| \frac{u-1}{u+1} \right| + C = \frac{1}{2} \ln \left(\frac{|e^x - 1|}{e^x + 1} \right) + C.$$

$$\begin{aligned} 75. \int \sin x \sin 2x \sin 3x dx &= \int \sin x \cdot \frac{1}{2} [\cos(2x - 3x) - \cos(2x + 3x)] dx = \frac{1}{2} \int (\sin x \cos x - \sin x \cos 5x) dx \\ &= \frac{1}{4} \int \sin 2x dx - \frac{1}{2} \int \frac{1}{2} [\sin(x + 5x) + \sin(x - 5x)] dx \\ &= -\frac{1}{8} \cos 2x - \frac{1}{4} \int (\sin 6x - \sin 4x) dx = -\frac{1}{8} \cos 2x + \frac{1}{24} \cos 6x - \frac{1}{16} \cos 4x + C \end{aligned}$$

$$\begin{aligned} 76. \int (x^2 - bx) \sin 2x dx &= -\frac{1}{2} (x^2 - bx) \cos 2x + \frac{1}{2} \int (2x - b) \cos 2x dx \\ &\quad [u = x^2 - bx, dv = \sin 2x dx, du = (2x - b) dx, v = -\frac{1}{2} \cos 2x] \\ &= -\frac{1}{2} (x^2 - bx) \cos 2x + \frac{1}{2} \left[\frac{1}{2} (2x - b) \sin 2x - \int \sin 2x dx \right] \\ &\quad [U = 2x - b, dV = \cos 2x dx, dU = 2 dx, V = \frac{1}{2} \sin 2x] \\ &= -\frac{1}{2} (x^2 - bx) \cos 2x + \frac{1}{4} (2x - b) \sin 2x + \frac{1}{4} \cos 2x + C \end{aligned}$$

77. Let $u = x^{3/2}$ so that $u^2 = x^3$ and $du = \frac{3}{2}x^{1/2} dx \Rightarrow \sqrt{x} dx = \frac{2}{3} du$. Then

$$\int \frac{\sqrt{x}}{1+x^3} dx = \int \frac{\frac{2}{3}}{1+u^2} du = \frac{2}{3} \tan^{-1} u + C = \frac{2}{3} \tan^{-1}(x^{3/2}) + C.$$

$$\begin{aligned} 78. \int \frac{\sec x \cos 2x}{\sin x + \sec x} dx &= \int \frac{\sec x \cos 2x}{\sin x + \sec x} \cdot \frac{2 \cos x}{2 \cos x} dx = \int \frac{2 \cos 2x}{2 \sin x \cos x + 2} dx \\ &= \int \frac{2 \cos 2x}{\sin 2x + 2} dx = \int \frac{1}{u} du \quad \left[\begin{array}{l} u = \sin 2x + 2, \\ du = 2 \cos 2x dx \end{array} \right] \\ &= \ln |u| + C = \ln |\sin 2x + 2| + C = \ln(\sin 2x + 2) + C \end{aligned}$$

79. Let $u = x$, $dv = \sin^2 x \cos x dx \Rightarrow du = dx$, $v = \frac{1}{3} \sin^3 x$. Then

$$\begin{aligned} \int x \sin^2 x \cos x dx &= \frac{1}{3} x \sin^3 x - \int \frac{1}{3} \sin^3 x dx = \frac{1}{3} x \sin^3 x - \frac{1}{3} \int (1 - \cos^2 x) \sin x dx \\ &= \frac{1}{3} x \sin^3 x + \frac{1}{3} \int (1 - y^2) dy \quad \left[\begin{array}{l} y = \cos x, \\ dy = -\sin x dx \end{array} \right] \\ &= \frac{1}{3} x \sin^3 x + \frac{1}{3} y - \frac{1}{9} y^3 + C = \frac{1}{3} x \sin^3 x + \frac{1}{3} \cos x - \frac{1}{9} \cos^3 x + C \end{aligned}$$

$$\begin{aligned} 80. \int \frac{\sin x \cos x}{\sin^4 x + \cos^4 x} dx &= \int \frac{\sin x \cos x}{(\sin^2 x)^2 + (\cos^2 x)^2} dx = \int \frac{\sin x \cos x}{(\sin^2 x)^2 + (1 - \sin^2 x)^2} dx \\ &= \int \frac{1}{u^2 + (1-u)^2} \left(\frac{1}{2} du \right) \quad \left[\begin{array}{l} u = \sin^2 x, \\ du = 2 \sin x \cos x dx \end{array} \right] \\ &= \int \frac{1}{4u^2 - 4u + 2} du = \int \frac{1}{(4u^2 - 4u + 1) + 1} du \\ &= \int \frac{1}{(2u-1)^2 + 1} du = \frac{1}{2} \int \frac{1}{y^2 + 1} dy \quad \left[\begin{array}{l} y = 2u - 1, \\ dy = 2 du \end{array} \right] \\ &= \frac{1}{2} \tan^{-1} y + C = \frac{1}{2} \tan^{-1}(2u - 1) + C = \frac{1}{2} \tan^{-1}(2 \sin^2 x - 1) + C \end{aligned}$$

Another solution:

$$\begin{aligned} \int \frac{\sin x \cos x}{\sin^4 x + \cos^4 x} dx &= \int \frac{(\sin x \cos x)/\cos^4 x}{(\sin^4 x + \cos^4 x)/\cos^4 x} dx = \int \frac{\tan x \sec^2 x}{\tan^4 x + 1} dx \\ &= \int \frac{1}{u^2 + 1} \left(\frac{1}{2} du \right) \quad \left[\begin{array}{l} u = \tan^2 x, \\ du = 2 \tan x \sec^2 x dx \end{array} \right] \\ &= \frac{1}{2} \tan^{-1} u + C = \frac{1}{2} \tan^{-1}(\tan^2 x) + C \end{aligned}$$

81. The function $y = 2xe^{x^2}$ does have an elementary antiderivative, so we'll use this fact to help evaluate the integral.

$$\begin{aligned} \int (2x^2 + 1)e^{x^2} dx &= \int 2x^2 e^{x^2} dx + \int e^{x^2} dx = \int x(2xe^{x^2}) dx + \int e^{x^2} dx \\ &= xe^{x^2} - \int e^{x^2} dx + \int e^{x^2} dx \quad \left[\begin{array}{l} u = x, \quad dv = 2xe^{x^2} dx, \\ du = dx \quad v = e^{x^2} \end{array} \right] = xe^{x^2} + C \end{aligned}$$

8.6 Integration Using Tables and Computer Algebra Systems

Keep in mind that there are several ways to approach many of these exercises, and different methods can lead to different forms of the answer.

1. We could make the substitution $u = \sqrt{2}x$ to obtain the radical $\sqrt{7-u^2}$ and then use Formula 33 with $a = \sqrt{7}$.
Alternatively, we will factor $\sqrt{2}$ out of the radical and use $a = \sqrt{\frac{7}{2}}$.

$$\begin{aligned}\int \frac{\sqrt{7-2x^2}}{x^2} dx &= \sqrt{2} \int \frac{\sqrt{\frac{7}{2}-x^2}}{x^2} dx \stackrel{33}{=} \sqrt{2} \left[-\frac{1}{x} \sqrt{\frac{7}{2}-x^2} - \sin^{-1} \frac{x}{\sqrt{\frac{7}{2}}} \right] + C \\ &= -\frac{1}{x} \sqrt{7-2x^2} - \sqrt{2} \sin^{-1} \left(\sqrt{\frac{2}{7}} x \right) + C\end{aligned}$$

$$\begin{aligned}2. \int \frac{3x}{\sqrt{3-2x}} dx &= 3 \int \frac{x}{\sqrt{3+(-2)x}} dx \stackrel{55}{=} 3 \left[\frac{2}{3(-2)^2} (-2x-2 \cdot 3) \sqrt{3+(-2)x} \right] + C \\ &= \frac{1}{2} (-2x-6) \sqrt{3-2x} + C = -(x+3) \sqrt{3-2x} + C\end{aligned}$$

3. Let $u = \pi x \Rightarrow du = \pi dx$, so

$$\begin{aligned}\int \sec^3(\pi x) dx &= \frac{1}{\pi} \int \sec^3 u du \stackrel{71}{=} \frac{1}{\pi} \left(\frac{1}{2} \sec u \tan u + \frac{1}{2} \ln |\sec u + \tan u| \right) + C \\ &= \frac{1}{2\pi} \sec \pi x \tan \pi x + \frac{1}{2\pi} \ln |\sec \pi x + \tan \pi x| + C\end{aligned}$$

$$4. \int e^{2\theta} \sin 3\theta d\theta \stackrel{98}{=} \frac{e^{2\theta}}{2^2 + 3^2} (2 \sin 3\theta - 3 \cos 3\theta) + C = \frac{2}{13} e^{2\theta} \sin 3\theta - \frac{3}{13} e^{2\theta} \cos 3\theta + C$$

$$5. \int_0^1 2x \cos^{-1} x dx \stackrel{91}{=} 2 \left[\frac{2x^2-1}{4} \cos^{-1} x - \frac{x \sqrt{1-x^2}}{4} \right]_0^1 = 2 \left[\left(\frac{1}{4} \cdot 0 - 0 \right) - \left(-\frac{1}{4} \cdot \frac{\pi}{2} - 0 \right) \right] = 2 \left(\frac{\pi}{8} \right) = \frac{\pi}{4}$$

$$\begin{aligned}6. \int_2^3 \frac{1}{x^2 \sqrt{4x^2-7}} dx &= \int_4^6 \frac{1}{\left(\frac{1}{2}u\right)^2 \sqrt{u^2-7}} \left(\frac{1}{2} du\right) \quad [u = 2x, du = 2 dx] \\ &= 2 \int_4^6 \frac{du}{u^2 \sqrt{u^2-7}} \stackrel{45}{=} 2 \left[\frac{\sqrt{u^2-7}}{7u} \right]_4^6 \\ &= 2 \left(\frac{\sqrt{29}}{42} - \frac{3}{28} \right) = \frac{\sqrt{29}}{21} - \frac{3}{14}\end{aligned}$$

7. By Formula 99 with $a = -3$ and $b = 4$,

$$\int e^{-3x} \cos 4x dx = \frac{e^{-3x}}{(-3)^2 + 4^2} (-3 \cos 4x + 4 \sin 4x) + C = \frac{e^{-3x}}{25} (-3 \cos 4x + 4 \sin 4x) + C.$$

8. Let $u = x/2$, so $dx = 2 du$, and we use Formula 72:

$$\begin{aligned}\int \csc^3(x/2) dx &= 2 \int \csc^3 u du = -\csc u \cot u + \ln |\csc u - \cot u| + C \\ &= -\csc(x/2) \cot(x/2) + \ln |\csc(x/2) - \cot(x/2)| + C\end{aligned}$$

9. Let $u = 2x$ and $a = 3$. Then $du = 2 dx$ and

$$\begin{aligned}\int \frac{dx}{x^2 \sqrt{4x^2+9}} &= \int \frac{\frac{1}{2} du}{\frac{u^2}{4} \sqrt{u^2+a^2}} = 2 \int \frac{du}{u^2 \sqrt{a^2+u^2}} \stackrel{28}{=} -2 \frac{\sqrt{a^2+u^2}}{a^2 u} + C \\ &= -2 \frac{\sqrt{4x^2+9}}{9 \cdot 2x} + C = -\frac{\sqrt{4x^2+9}}{9x} + C\end{aligned}$$

10. Let $u = \sqrt{2}y$ and $a = \sqrt{3}$. Then $du = \sqrt{2}dy$ and

$$\begin{aligned}\int \frac{\sqrt{2y^2-3}}{y^2} dy &= \int \frac{\sqrt{u^2-a^2}}{\frac{1}{2}u^2} \frac{du}{\sqrt{2}} = \sqrt{2} \int \frac{\sqrt{u^2-a^2}}{u^2} du \\ &\stackrel{42}{=} \sqrt{2} \left(-\frac{\sqrt{u^2-a^2}}{u} + \ln|u + \sqrt{u^2-a^2}| \right) + C \\ &= \sqrt{2} \left(-\frac{\sqrt{2y^2-3}}{\sqrt{2}y} + \ln|\sqrt{2}y + \sqrt{2y^2-3}| \right) + C \\ &= -\frac{\sqrt{2y^2-3}}{y} + \sqrt{2} \ln|\sqrt{2}y + \sqrt{2y^2-3}| + C\end{aligned}$$

11. $\int_{-1}^0 t^2 e^{-t} dt \stackrel{97}{=} \left[\frac{1}{-1} t^2 e^{-t} \right]_{-1}^0 - \frac{2}{-1} \int_{-1}^0 t e^{-t} dt = e + 2 \int_{-1}^0 t e^{-t} dt \stackrel{96}{=} e + 2 \left[\frac{1}{(-1)^2} (-t-1) e^{-t} \right]_{-1}^0$
 $= e + 2[-e^0 + 0] = e - 2$

12. Let $u = 3x$. Then $du = 3dx$, so

$$\begin{aligned}\int x^2 \cos 3x dx &= \frac{1}{27} \int u^2 \cos u du \stackrel{85}{=} \frac{1}{27} (u^2 \sin u - 2 \int u \sin u du) \\ &\stackrel{82}{=} \frac{1}{3} x^2 \sin 3x - \frac{2}{27} (\sin 3x - 3x \cos 3x) + C \\ &= \frac{1}{27} [(9x^2 - 2) \sin 3x + 6x \cos 3x] + C\end{aligned}$$

$$\text{Thus, } \int_0^\pi x^2 \cos 3x dx = \frac{1}{27} [(9x^2 - 2) \sin 3x + 6x \cos 3x]_0^\pi = \frac{1}{27} [(0 + 6\pi(-1)) - (0 + 0)] = -\frac{6\pi}{27} = -\frac{2\pi}{9}.$$

13. $\int \frac{\tan^3(1/z)}{z^2} dz \quad \left[\begin{array}{l} u = 1/z, \\ du = -dz/z^2 \end{array} \right] = -\int \tan^3 u du \stackrel{69}{=} -\frac{1}{2} \tan^2 u - \ln|\cos u| + C$
 $= -\frac{1}{2} \tan^2\left(\frac{1}{z}\right) - \ln\left|\cos\left(\frac{1}{z}\right)\right| + C$

14. Let $u = \sqrt{x}$. Then $u^2 = x$ and $2u du = dx$, so

$$\begin{aligned}\int \sin^{-1} \sqrt{x} dx &= 2 \int u \sin^{-1} u du \stackrel{90}{=} \frac{2u^2-1}{2} \sin^{-1} u + \frac{u\sqrt{1-u^2}}{2} + C \\ &= \frac{2x-1}{2} \sin^{-1} \sqrt{x} + \frac{\sqrt{x(1-x)}}{2} + C\end{aligned}$$

15. Let $u = e^x$. Then $du = e^x dx$, so $\int e^x \operatorname{sech}(e^x) dx = \int \operatorname{sech} u du \stackrel{107}{=} \tan^{-1}|\sinh u| + C = \tan^{-1}[\sinh(e^x)] + C$

16. Let $u = x^2$, so that $du = 2x dx$. Then

$$\begin{aligned}\int x \sin(x^2) \cos(3x^2) dx &= \frac{1}{2} \int \sin u \cos 3u du \stackrel{81}{=} -\frac{1}{2} \frac{\cos(1-3)u}{2(1-3)} - \frac{1}{2} \frac{\cos(1+3)u}{2(1+3)} + C \\ &= \frac{1}{8} \cos 2u - \frac{1}{16} \cos 4u + C = \frac{1}{8} \cos(2x^2) - \frac{1}{16} \cos(4x^2) + C\end{aligned}$$

17. Let $z = 6 + 4y - 4y^2 = 6 - (4y^2 - 4y + 1) + 1 = 7 - (2y - 1)^2$, $u = 2y - 1$, and $a = \sqrt{7}$. Then $z = a^2 - u^2$, $du = 2 dy$, and

$$\begin{aligned} \int y \sqrt{6 + 4y - 4y^2} dy &= \int y \sqrt{z} dy = \int \frac{1}{2}(u + 1) \sqrt{a^2 - u^2} \frac{1}{2} du \\ &= \frac{1}{4} \int u \sqrt{a^2 - u^2} du + \frac{1}{4} \int \sqrt{a^2 - u^2} du \\ &= \frac{1}{4} \int \sqrt{a^2 - u^2} du - \frac{1}{8} \int (-2u) \sqrt{a^2 - u^2} du \\ &\stackrel{30}{=} \frac{u}{8} \sqrt{a^2 - u^2} + \frac{a^2}{8} \sin^{-1} \left(\frac{u}{a} \right) - \frac{1}{8} \int \sqrt{w} dw \quad \left[\begin{array}{l} w = a^2 - u^2, \\ dw = -2u du \end{array} \right] \\ &= \frac{2y - 1}{8} \sqrt{6 + 4y - 4y^2} + \frac{7}{8} \sin^{-1} \frac{2y - 1}{\sqrt{7}} - \frac{1}{8} \cdot \frac{2}{3} w^{3/2} + C \\ &= \frac{2y - 1}{8} \sqrt{6 + 4y - 4y^2} + \frac{7}{8} \sin^{-1} \frac{2y - 1}{\sqrt{7}} - \frac{1}{12} (6 + 4y - 4y^2)^{3/2} + C. \end{aligned}$$

This can be rewritten as

$$\begin{aligned} \sqrt{6 + 4y - 4y^2} \left[\frac{1}{8}(2y - 1) - \frac{1}{12}(6 + 4y - 4y^2) \right] + \frac{7}{8} \sin^{-1} \frac{2y - 1}{\sqrt{7}} + C \\ = \left(\frac{1}{3}y^2 - \frac{1}{12}y - \frac{5}{8} \right) \sqrt{6 + 4y - 4y^2} + \frac{7}{8} \sin^{-1} \left(\frac{2y - 1}{\sqrt{7}} \right) + C \\ = \frac{1}{24} (8y^2 - 2y - 15) \sqrt{6 + 4y - 4y^2} + \frac{7}{8} \sin^{-1} \left(\frac{2y - 1}{\sqrt{7}} \right) + C \end{aligned}$$

18. Let $u = x^2$. Then $du = 2x dx$, so by Formula 48,

$$\begin{aligned} \int \frac{x^5 dx}{x^2 + \sqrt{2}} &= \frac{1}{2} \int \frac{u^2}{u + \sqrt{2}} du = \frac{1}{2} \cdot \frac{1}{2} \left[(u + \sqrt{2})^2 - 4\sqrt{2}(u + \sqrt{2}) + 4 \ln|u + \sqrt{2}| \right] + C \\ &= \frac{1}{4} \left[(x^2 + \sqrt{2})^2 - 4\sqrt{2}(x^2 + \sqrt{2}) + 4 \ln(x^2 + \sqrt{2}) \right] + C \\ &= \frac{1}{4} x^4 - \frac{1}{\sqrt{2}} x^2 + \ln(x^2 + \sqrt{2}) + K \end{aligned}$$

Or: Let $u = x^2 + \sqrt{2}$.

19. Let $u = \sin x$. Then $du = \cos x dx$, so

$$\begin{aligned} \int \sin^2 x \cos x \ln(\sin x) dx &= \int u^2 \ln u du \stackrel{101}{=} \frac{u^{2+1}}{(2+1)^2} [(2+1) \ln u - 1] + C = \frac{1}{9} u^3 (3 \ln u - 1) + C \\ &= \frac{1}{9} \sin^3 x [3 \ln(\sin x) - 1] + C \end{aligned}$$

20. Let $u = e^x$. Then $x = \ln u$, $dx = du/u$, so

$$\begin{aligned} \int \frac{dx}{e^x(1 + 2e^x)} &= \int \frac{du/u}{u(1 + 2u)} = \int \frac{du}{u^2(1 + 2u)} \stackrel{50}{=} -\frac{1}{u} + 2 \ln \left| \frac{1 + 2u}{u} \right| + C \\ &= -e^{-x} + 2 \ln(e^{-x} + 2) + C \end{aligned}$$

21. Let $u = e^x$ and $a = \sqrt{3}$. Then $du = e^x dx$ and

$$\int \frac{e^x}{3 - e^{2x}} dx = \int \frac{du}{a^2 - u^2} \stackrel{19}{=} \frac{1}{2a} \ln \left| \frac{u + a}{u - a} \right| + C = \frac{1}{2\sqrt{3}} \ln \left| \frac{e^x + \sqrt{3}}{e^x - \sqrt{3}} \right| + C.$$

22. Let $u = x^2$ and $a = 2$. Then $du = 2x dx$ and

$$\begin{aligned}\int_0^2 x^3 \sqrt{4x^2 - x^4} dx &= \frac{1}{2} \int_0^2 x^2 \sqrt{2 \cdot 2 \cdot x^2 - (x^2)^2} \cdot 2x dx = \frac{1}{2} \int_0^4 u \sqrt{2au - u^2} du \\ &\stackrel{114}{=} \left[\frac{2u^2 - au - 3a^2}{12} \sqrt{2au - u^2} + \frac{a^3}{4} \cos^{-1} \left(\frac{a-u}{a} \right) \right]_0^4 \\ &= \left[\frac{2u^2 - 2u - 12}{12} \sqrt{4u - u^2} + \frac{8}{4} \cos^{-1} \left(\frac{2-u}{2} \right) \right]_0^4 \\ &= \left[\frac{u^2 - u - 6}{6} \sqrt{4u - u^2} + 2 \cos^{-1} \left(\frac{2-u}{2} \right) \right]_0^4 \\ &= [0 + 2 \cos^{-1}(-1)] - (0 + 2 \cos^{-1} 1) = 2 \cdot \pi - 2 \cdot 0 = 2\pi\end{aligned}$$

23. $\int \sec^5 x dx \stackrel{77}{=} \frac{1}{4} \tan x \sec^3 x + \frac{3}{4} \int \sec^3 x dx \stackrel{77}{=} \frac{1}{4} \tan x \sec^3 x + \frac{3}{4} \left(\frac{1}{2} \tan x \sec x + \frac{1}{2} \int \sec x dx \right)$
 $\stackrel{14}{=} \frac{1}{4} \tan x \sec^3 x + \frac{3}{8} \tan x \sec x + \frac{3}{8} \ln |\sec x + \tan x| + C$

24. Let $u = 2x$. Then $du = 2 dx$, so

$$\begin{aligned}\int \sin^6 2x dx &= \frac{1}{2} \int \sin^6 u du \stackrel{73}{=} \frac{1}{2} \left(-\frac{1}{6} \sin^5 u \cos u + \frac{5}{6} \int \sin^4 u du \right) \\ &\stackrel{73}{=} -\frac{1}{12} \sin^5 u \cos u + \frac{5}{12} \left(-\frac{1}{4} \sin^3 u \cos u + \frac{3}{4} \int \sin^2 u du \right) \\ &\stackrel{63}{=} -\frac{1}{12} \sin^5 u \cos u - \frac{5}{48} \sin^3 u \cos u + \frac{5}{16} \left(\frac{1}{2} u - \frac{1}{4} \sin 2u \right) + C \\ &= -\frac{1}{12} \sin^5 2x \cos 2x - \frac{5}{48} \sin^3 2x \cos 2x - \frac{5}{64} \sin 4x + \frac{5}{16} x + C\end{aligned}$$

25. Let $u = \ln x$ and $a = 2$. Then $du = \frac{dx}{x}$ and

$$\begin{aligned}\int \frac{\sqrt{4 + (\ln x)^2}}{x} dx &= \int \sqrt{a^2 + u^2} du \stackrel{21}{=} \frac{u}{2} \sqrt{a^2 + u^2} + \frac{a^2}{2} \ln(u + \sqrt{a^2 + u^2}) + C \\ &= \frac{1}{2} (\ln x) \sqrt{4 + (\ln x)^2} + 2 \ln [\ln x + \sqrt{4 + (\ln x)^2}] + C\end{aligned}$$

26. $\int x^4 e^{-x} dx \stackrel{97}{=} -x^4 e^{-x} + 4 \int x^3 e^{-x} dx \stackrel{97}{=} -x^4 e^{-x} + 4(-x^3 e^{-x} + 3 \int x^2 e^{-x} dx)$
 $\stackrel{97}{=} -(x^4 + 4x^3) e^{-x} + 12(-x^2 e^{-x} + 2 \int x e^{-x} dx)$
 $\stackrel{96}{=} -(x^4 + 4x^3 + 12x^2) e^{-x} + 24[(-x - 1) e^{-x}] + C$
 $= -(x^4 + 4x^3 + 12x^2 + 24x + 24) e^{-x} + C$

$$\begin{aligned}\text{So } \int_0^1 x^4 e^{-x} dx &= [-(x^4 + 4x^3 + 12x^2 + 24x + 24) e^{-x}]_0^1 \\ &= -(1 + 4 + 12 + 24 + 24) e^{-1} + 24 e^0 = 24 - 65 e^{-1}.\end{aligned}$$

27. Let $u = e^x$. Then $x = \ln u$, $dx = du/u$, so

$$\int \sqrt{e^{2x} - 1} dx = \int \frac{\sqrt{u^2 - 1}}{u} du \stackrel{41}{=} \sqrt{u^2 - 1} - \cos^{-1}(1/u) + C = \sqrt{e^{2x} - 1} - \cos^{-1}(e^{-x}) + C.$$

28. Let $u = \alpha t - 3$ and assume that $\alpha \neq 0$. Then $du = \alpha dt$ and

$$\begin{aligned}\int e^t \sin(\alpha t - 3) dt &= \frac{1}{\alpha} \int e^{(u+3)/\alpha} \sin u du = \frac{1}{\alpha} e^{3/\alpha} \int e^{(1/\alpha)u} \sin u du \\ &\stackrel{98}{=} \frac{1}{\alpha} e^{3/\alpha} \frac{e^{(1/\alpha)u}}{(1/\alpha)^2 + 1^2} \left(\frac{1}{\alpha} \sin u - \cos u \right) + C \\ &= \frac{1}{\alpha} e^{3/\alpha} e^{(1/\alpha)u} \frac{\alpha^2}{1 + \alpha^2} \left(\frac{1}{\alpha} \sin u - \cos u \right) + C \\ &= \frac{1}{1 + \alpha^2} e^{(u+3)/\alpha} (\sin u - \alpha \cos u) + C \\ &= \frac{1}{1 + \alpha^2} e^t [\sin(\alpha t - 3) - \alpha \cos(\alpha t - 3)] + C\end{aligned}$$

29. $\int \frac{x^4 dx}{\sqrt{x^{10} - 2}} = \int \frac{x^4 dx}{\sqrt{(x^5)^2 - 2}} = \frac{1}{5} \int \frac{du}{\sqrt{u^2 - 2}} \quad [u = x^5, du = 5x^4 dx]$

$$\stackrel{43}{=} \frac{1}{5} \ln|u + \sqrt{u^2 - 2}| + C = \frac{1}{5} \ln|x^5 + \sqrt{x^{10} - 2}| + C$$

30. Let $u = \tan \theta$ and $a = 3$. Then $du = \sec^2 \theta d\theta$ and

$$\begin{aligned}\int \frac{\sec^2 \theta \tan^2 \theta}{\sqrt{9 - \tan^2 \theta}} d\theta &= \int \frac{u^2}{\sqrt{a^2 - u^2}} du \stackrel{34}{=} -\frac{u}{2} \sqrt{a^2 - u^2} + \frac{a^2}{2} \sin^{-1} \left(\frac{u}{a} \right) + C \\ &= -\frac{1}{2} \tan \theta \sqrt{9 - \tan^2 \theta} + \frac{9}{2} \sin^{-1} \left(\frac{\tan \theta}{3} \right) + C\end{aligned}$$

31. Using cylindrical shells, we get

$$\begin{aligned}V &= 2\pi \int_0^2 x \cdot x \sqrt{4 - x^2} dx = 2\pi \int_0^2 x^2 \sqrt{4 - x^2} dx \stackrel{31}{=} 2\pi \left[\frac{x}{8} (2x^2 - 4) \sqrt{4 - x^2} + \frac{16}{8} \sin^{-1} \frac{x}{2} \right]_0^2 \\ &= 2\pi [(0 + 2 \sin^{-1} 1) - (0 + 2 \sin^{-1} 0)] = 2\pi \left(2 \cdot \frac{\pi}{2} \right) = 2\pi^2\end{aligned}$$

32. Using disks, we get

$$\begin{aligned}\text{Volume} &= \int_0^{\pi/4} \pi \tan^4 x dx \stackrel{75}{=} \pi \left(\left[\frac{1}{3} \tan^3 x \right]_0^{\pi/4} - \int_0^{\pi/4} \tan^2 x dx \right) \stackrel{65}{=} \pi \left[\frac{1}{3} \tan^3 x - \tan x + x \right]_0^{\pi/4} \\ &= \pi \left(\frac{1}{3} - 1 + \frac{\pi}{4} \right) = \pi \left(\frac{\pi}{4} - \frac{2}{3} \right)\end{aligned}$$

33. (a) $\frac{d}{du} \left[\frac{1}{b^3} \left(a + bu - \frac{a^2}{a + bu} - 2a \ln |a + bu| \right) + C \right] = \frac{1}{b^3} \left[b + \frac{ba^2}{(a + bu)^2} - \frac{2ab}{(a + bu)} \right]$

$$= \frac{1}{b^3} \left[\frac{b(a + bu)^2 + ba^2 - (a + bu)2ab}{(a + bu)^2} \right] = \frac{1}{b^3} \left[\frac{b^3 u^2}{(a + bu)^2} \right] = \frac{u^2}{(a + bu)^2}$$

(b) Let $t = a + bu \Rightarrow dt = b du$. Note that $u = \frac{t - a}{b}$ and $du = \frac{1}{b} dt$.

$$\begin{aligned}\int \frac{u^2 du}{(a + bu)^2} &= \frac{1}{b^3} \int \frac{(t - a)^2}{t^2} dt = \frac{1}{b^3} \int \frac{t^2 - 2at + a^2}{t^2} dt \\ &= \frac{1}{b^3} \int \left(1 - \frac{2a}{t} + \frac{a^2}{t^2} \right) dt = \frac{1}{b^3} \left(t - 2a \ln |t| - \frac{a^2}{t} \right) + C \\ &= \frac{1}{b^3} \left(a + bu - \frac{a^2}{a + bu} - 2a \ln |a + bu| \right) + C\end{aligned}$$

$$\begin{aligned}
 34. \text{ (a) } \frac{d}{du} \left[\frac{u}{8} (2u^2 - a^2) \sqrt{a^2 - u^2} + \frac{a^4}{8} \sin^{-1} \frac{u}{a} + C \right] \\
 &= \frac{u}{8} (2u^2 - a^2) \frac{-u}{\sqrt{a^2 - u^2}} + \sqrt{a^2 - u^2} \left[\frac{u}{8} (4u) + (2u^2 - a^2) \frac{1}{8} \right] + \frac{a^4}{8} \frac{1/a}{\sqrt{1 - u^2/a^2}} \\
 &= -\frac{u^2(2u^2 - a^2)}{8\sqrt{a^2 - u^2}} + \sqrt{a^2 - u^2} \left[\frac{u^2}{2} + \frac{2u^2 - a^2}{8} \right] + \frac{a^4}{8\sqrt{a^2 - u^2}} \\
 &= \frac{1}{2} (a^2 - u^2)^{-1/2} \left[-\frac{u^2}{4} (2u^2 - a^2) + u^2 (a^2 - u^2) + \frac{1}{4} (a^2 - u^2) (2u^2 - a^2) + \frac{a^4}{4} \right] \\
 &= \frac{1}{2} (a^2 - u^2)^{-1/2} [2u^2 a^2 - 2u^4] = \frac{u^2(a^2 - u^2)}{\sqrt{a^2 - u^2}} = u^2 \sqrt{a^2 - u^2}
 \end{aligned}$$

(b) Let $u = a \sin \theta \Rightarrow du = a \cos \theta d\theta$. Then

$$\begin{aligned}
 \int u^2 \sqrt{a^2 - u^2} du &= \int a^2 \sin^2 \theta a \sqrt{1 - \sin^2 \theta} a \cos \theta d\theta = a^4 \int \sin^2 \theta \cos^2 \theta d\theta \\
 &= a^4 \int \frac{1}{2} (1 + \cos 2\theta) \frac{1}{2} (1 - \cos 2\theta) d\theta = \frac{1}{4} a^4 \int (1 - \cos^2 2\theta) d\theta \\
 &= \frac{1}{4} a^4 \int [1 - \frac{1}{2} (1 + \cos 4\theta)] d\theta = \frac{1}{4} a^4 (\frac{1}{2} \theta - \frac{1}{8} \sin 4\theta) + C \\
 &= \frac{1}{4} a^4 (\frac{1}{2} \theta - \frac{1}{8} 2 \sin 2\theta \cos 2\theta) + C = \frac{1}{4} a^4 [\frac{1}{2} \theta - \frac{1}{2} \sin \theta \cos \theta (1 - 2 \sin^2 \theta)] + C \\
 &= \frac{a^4}{8} \left[\sin^{-1} \frac{u}{a} - \frac{u}{a} \frac{\sqrt{a^2 - u^2}}{a} \left(1 - \frac{2u^2}{a^2} \right) \right] + C \\
 &= \frac{a^4}{8} \left[\sin^{-1} \frac{u}{a} - \frac{u}{a} \frac{\sqrt{a^2 - u^2}}{a} \frac{a^2 - 2u^2}{a^2} \right] + C \\
 &= \frac{u}{8} (2u^2 - a^2) \sqrt{a^2 - u^2} + \frac{a^4}{8} \sin^{-1} \frac{u}{a} + C
 \end{aligned}$$

35. Maple, Mathematica and Derive all give $\int x^2 \sqrt{5 - x^2} dx = -\frac{1}{4} x (5 - x^2)^{3/2} + \frac{5}{8} x \sqrt{5 - x^2} + \frac{25}{8} \sin^{-1} \left(\frac{1}{\sqrt{5}} x \right)$.

Using Formula 31, we get $\int x^2 \sqrt{5 - x^2} dx = \frac{1}{8} x (2x^2 - 5) \sqrt{5 - x^2} + \frac{1}{8} (5^2) \sin^{-1} \left(\frac{1}{\sqrt{5}} x \right) + C$. But

$-\frac{1}{4} x (5 - x^2)^{3/2} + \frac{5}{8} x \sqrt{5 - x^2} = \frac{1}{8} x \sqrt{5 - x^2} [5 - 2(5 - x^2)] = \frac{1}{8} x (2x^2 - 5) \sqrt{5 - x^2}$, and the $\sin^{-1}$ terms are the same in each expression, so the answers are equivalent.

36. Maple and Mathematica both give $\int x^2 (1 + x^3)^4 dx = \frac{1}{15} x^{15} + \frac{1}{3} x^{12} + \frac{2}{3} x^9 + \frac{2}{3} x^6 + \frac{1}{3} x^3$, while Derive gives

$\int x^2 (1 + x^3)^4 dx = \frac{1}{15} (x^3 + 1)^5$. Using the substitution $u = 1 + x^3 \Rightarrow du = 3x^2 dx$, we get

$\int x^2 (1 + x^3)^4 dx = \int u^4 (\frac{1}{3} du) = \frac{1}{15} u^5 + C = \frac{1}{15} (1 + x^3)^5 + C$. We can use the Binomial Theorem or a CAS to expand this expression, and we get $\frac{1}{15} (1 + x^3)^5 + C = \frac{1}{15} + \frac{1}{3} x^3 + \frac{2}{3} x^6 + \frac{2}{3} x^9 + \frac{1}{3} x^{12} + \frac{1}{15} x^{15} + C$.

37. Maple and Derive both give $\int \sin^3 x \cos^2 x dx = -\frac{1}{5} \sin^2 x \cos^3 x - \frac{2}{15} \cos^3 x$ (although Derive factors the expression), and Mathematica gives $\int \sin^3 x \cos^2 x dx = -\frac{1}{8} \cos x - \frac{1}{48} \cos 3x + \frac{1}{80} \cos 5x$. We can use a CAS to show that both of these expressions are equal to $-\frac{1}{3} \cos^3 x + \frac{1}{5} \cos^5 x$. Using Formula 86, we write

$$\begin{aligned}
 \int \sin^3 x \cos^2 x dx &= -\frac{1}{5} \sin^2 x \cos^3 x + \frac{2}{5} \int \sin x \cos^2 x dx = -\frac{1}{5} \sin^2 x \cos^3 x + \frac{2}{5} \left(-\frac{1}{3} \cos^3 x \right) + C \\
 &= -\frac{1}{5} \sin^2 x \cos^3 x - \frac{2}{15} \cos^3 x + C
 \end{aligned}$$

38. Maple gives $\int \tan^2 x \sec^4 x \, dx = \frac{1}{5} \frac{\sin^3 x}{\cos^5 x} + \frac{2}{15} \frac{\sin^3 x}{\cos^3 x}$,

Mathematica gives $\int \tan^2 x \sec^4 x \, dx = -\frac{1}{120} \sec^5 x (-20 \sin x + 5 \sin 3x + \sin 5x)$, and

Derive gives $\int \tan^2 x \sec^4 x \, dx = -\frac{2}{15} \tan x - \frac{\sin x}{15 \cos^3 x} + \frac{\sin x}{5 \cos^5 x}$. All of these expressions can be “simplified”

to $-\frac{1}{15} \frac{\sin x (\cos^2 x - 2 \cos^4 x - 3)}{\cos^5 x}$ using Maple. Using the identity $1 + \tan^2 x = \sec^2 x$, we write

$$\int \tan^2 x \sec^4 x \, dx = \int \tan^2 x (1 + \tan^2 x) \sec^2 x \, dx = \int (\tan^2 x + \tan^4 x) \sec^2 x \, dx.$$

Now we substitute $u = \tan x \Rightarrow du = \sec^2 x \, dx$, and the integral becomes

$$\int (u^2 + u^4) \, du = \frac{1}{3} u^3 + \frac{1}{5} u^5 + C = \frac{1}{3} \tan^3 x + \frac{1}{5} \tan^5 x + C. \text{ If we write}$$

$\sin^5 x = \sin^3 x (1 - \cos^2 x)$ and substitute into the numerator of the $\tan^5 x$ term, this becomes

$$\frac{1}{3} \frac{\sin^3 x}{\cos^3 x} + \frac{1}{5} \frac{\sin^3 x (1 - \cos^2 x)}{\cos^5 x} + C = \frac{1}{5} \frac{\sin^3 x}{\cos^5 x} + \left(\frac{1}{3} - \frac{1}{5} \right) \frac{\sin^3 x}{\cos^3 x} + C = \frac{1}{5} \frac{\sin^3 x}{\cos^5 x} + \frac{2}{15} \frac{\sin^3 x}{\cos^3 x} + C,$$

which is the same as Maple’s expression.

39. Maple gives $\int x \sqrt{1+2x} \, dx = \frac{1}{10} (1+2x)^{5/2} - \frac{1}{6} (1+2x)^{3/2}$, Mathematica gives $\sqrt{1+2x} (\frac{2}{5} x^2 + \frac{1}{15} x - \frac{1}{15})$, and Derive gives $\frac{1}{15} (1+2x)^{3/2} (3x-1)$. The first two expressions can be simplified to Derive’s result. If we use Formula 54, we get

$$\begin{aligned} \int x \sqrt{1+2x} \, dx &= \frac{2}{15(2)^2} (3 \cdot 2x - 2 \cdot 1) (1+2x)^{3/2} + C = \frac{1}{30} (6x-2) (1+2x)^{3/2} + C \\ &= \frac{1}{15} (3x-1) (1+2x)^{3/2} \end{aligned}$$

40. Maple and Derive both give $\int \sin^4 x \, dx = -\frac{1}{4} \sin^3 x \cos x - \frac{3}{8} \cos x \sin x + \frac{3}{8} x$, while Mathematica gives $\frac{1}{32} (12x - 8 \sin 2x + \sin 4x)$, which can be expanded and simplified to give the other expression. Now

$$\begin{aligned} \int \sin^4 x \, dx &\stackrel{73}{=} -\frac{1}{4} \sin^3 x \cos x + \frac{3}{4} \int \sin^2 x \, dx \stackrel{63}{=} -\frac{1}{4} \sin^3 x \cos x + \frac{3}{4} \left(\frac{1}{2} x - \frac{1}{4} \sin 2x \right) + C \\ &= -\frac{1}{4} \sin^3 x \cos x - \frac{3}{8} \sin x \cos x + \frac{3}{8} x + C \text{ since } \sin 2x = 2 \sin x \cos x \end{aligned}$$

41. Maple gives $\int \tan^5 x \, dx = \frac{1}{4} \tan^4 x - \frac{1}{2} \tan^2 x + \frac{1}{2} \ln(1 + \tan^2 x)$, Mathematica gives $\int \tan^5 x \, dx = \frac{1}{4} [-1 - 2 \cos(2x)] \sec^4 x - \ln(\cos x)$, and Derive gives $\int \tan^5 x \, dx = \frac{1}{4} \tan^4 x - \frac{1}{2} \tan^2 x - \ln(\cos x)$. These expressions are equivalent, and none includes absolute value bars or a constant of integration. Note that Mathematica’s and Derive’s expressions suggest that the integral is undefined where $\cos x < 0$, which is not the case. Using Formula 75, $\int \tan^5 x \, dx = \frac{1}{5-1} \tan^{5-1} x - \int \tan^{5-2} x \, dx = \frac{1}{4} \tan^4 x - \int \tan^3 x \, dx$. Using Formula 69, $\int \tan^3 x \, dx = \frac{1}{2} \tan^2 x + \ln |\cos x| + C$, so $\int \tan^5 x \, dx = \frac{1}{4} \tan^4 x - \frac{1}{2} \tan^2 x - \ln |\cos x| + C$.
42. Maple gives $\int x^5 \sqrt{x^2+1} \, dx = \frac{1}{35} x^4 \sqrt{1+x^2} - \frac{4}{105} x^2 \sqrt{1+x^2} + \frac{8}{105} \sqrt{1+x^2} + \frac{1}{7} x^6 \sqrt{1+x^2}$. When we use the factor command on this expression, it becomes $\frac{1}{105} (1+x^2)^{3/2} (15x^4 - 12x^2 + 8)$. Mathematica gives $\sqrt{1+x^2} (\frac{8}{105} - \frac{4}{105} x^2 + \frac{1}{35} x^4 + \frac{1}{7} x^6)$, which again factors to give the above expression, and Derive gives the factored form immediately. If we substitute $u = \sqrt{x^2+1} \Rightarrow x^4 = (u^2-1)^2, x \, dx = u \, du$, then the integral

becomes

$$\begin{aligned} \int (u^2 - 1)^2 u(u \, du) &= \int (u^4 - 2u^2 + 1)u^2 \, du = \frac{1}{7}u^7 - \frac{2}{5}u^5 + \frac{1}{3}u^3 + C \\ &= (x^2 + 1)^{3/2} \left[\frac{1}{7}(x^2 + 1)^2 - \frac{2}{5}(x^2 + 1) + \frac{1}{3} \right] + C \\ &= \frac{1}{105}(x^2 + 1)^{3/2} \left[15(x^2 + 1)^2 - 42(x^2 + 1) + 35 \right] + C \\ &= \frac{1}{105}(x^2 + 1)^{3/2} (15x^4 - 12x^2 + 8) + C \end{aligned}$$

- 43.** Derive gives $I = \int 2^x \sqrt{4^x - 1} dx = \frac{2^{x-1} \sqrt{2^{2x} - 1}}{\ln 2} - \frac{\ln(\sqrt{2^{2x} - 1} + 2^x)}{2 \ln 2}$ immediately. Neither Maple nor Mathematica is able to evaluate I in its given form. However, if we instead write I as $\int 2^x \sqrt{(2^x)^2 - 1} dx$, both systems give the same answer as Derive (after minor simplification). Our trick works because the CAS now recognizes 2^x as a promising substitution.
- 44.** None of Maple, Mathematica and Derive is able to evaluate $\int (1 + \ln x) \sqrt{1 + (x \ln x)^2} dx$. However, if we let $u = x \ln x$, then $du = (1 + \ln x) dx$ and the integral is simply $\int \sqrt{1 + u^2} du$, which any CAS can evaluate. The antiderivative is $\frac{1}{2} \ln \left(x \ln x + \sqrt{1 + (x \ln x)^2} \right) + \frac{1}{2} x \ln x \sqrt{1 + (x \ln x)^2} + C$.

- 45.** Maple gives the antiderivative

$$F(x) = \int \frac{x^2 - 1}{x^4 + x^2 + 1} dx = -\frac{1}{2} \ln(x^2 + x + 1) + \frac{1}{2} \ln(x^2 - x + 1).$$

We can see that at 0, this antiderivative is 0. From the graphs, it appears that F has a maximum at $x = -1$ and a minimum at $x = 1$ [since $F'(x) = f(x)$ changes sign at these x -values], and that F has inflection points at $x \approx -1.7$, $x = 0$, and $x \approx 1.7$ [since $f(x)$ has extrema at these x -values].

- 46.** Maple gives the antiderivative which, after we use the `simplify` command, becomes

$\int x e^{-x} \sin x \, dx = -\frac{1}{2} e^{-x} (\cos x + x \cos x + x \sin x)$. At $x = 0$, this antiderivative has the value $-\frac{1}{2}$, so we use $F(x) = -\frac{1}{2} e^{-x} (\cos x + x \cos x + x \sin x) + \frac{1}{2}$ to make $F(0) = 0$.

From the graphs, it appears that F has a minimum at $x \approx -3.1$ and a maximum at $x \approx 3.1$ [note that $f(x) = 0$ at $x = \pm\pi$], and that F has inflection points where f' changes sign, at $x \approx -2.5$, $x = 0$, $x \approx 1.3$ and $x \approx 4.1$.

47. Since $f(x) = \sin^4 x \cos^6 x$ is everywhere positive, we know that its antiderivative F is increasing. Maple gives

$$\int f(x) dx = -\frac{1}{10} \sin^3 x \cos^7 x - \frac{3}{80} \sin x \cos^7 x + \frac{1}{160} \cos^5 x \sin x + \frac{1}{128} \cos^3 x \sin x + \frac{3}{256} \cos x \sin x + \frac{3}{256} x$$

and this expression is 0 at $x = 0$.

F has a minimum at $x = 0$ and a maximum at $x = \pi$. F has inflection points where f' changes sign, that is, at $x \approx 0.7$, $x = \pi/2$, and $x \approx 2.5$.

48. From the graph of $f(x) = \frac{x^3 - x}{x^6 + 1}$, we can see that F has a maximum at $x = 0$, and minima at $x \approx \pm 1$. The

antiderivative given by Maple is $F(x) = -\frac{1}{3} \ln(x^2 + 1) + \frac{1}{6} \ln(x^4 - x^2 + 1)$, and $F(0) = 0$. Note that f is odd, and its antiderivative F is even.

F has inflection points where f' changes sign, that is, at $x \approx \pm 0.5$ and $x \approx \pm 1.4$.

DISCOVERY PROJECT Patterns in Integrals

1. (a) The CAS results are listed. Note that the absolute value symbols are missing, as is the familiar “+ C”.

$$(i) \int \frac{1}{(x+2)(x+3)} dx = \ln(x+2) - \ln(x+3)$$

$$(ii) \int \frac{1}{(x+1)(x+5)} dx = \frac{\ln(x+1)}{4} - \frac{\ln(x+5)}{4}$$

$$(iii) \int \frac{1}{(x+2)(x-5)} dx = \frac{\ln(x-5)}{7} - \frac{\ln(x+2)}{7}$$

$$(iv) \int \frac{1}{(x+2)^2} dx = -\frac{1}{x+2}$$

(b) If $a \neq b$, it appears that $\ln(x+a)$ is divided by $b-a$ and $\ln(x+b)$ is divided by $a-b$, so we guess that

$$\int \frac{1}{(x+a)(x+b)} dx = \frac{\ln(x+a)}{b-a} + \frac{\ln(x+b)}{a-b} + C$$

If $a = b$, as in part (a)(iv), it appears that

$$\int \frac{1}{(x+a)^2} dx = -\frac{1}{x+a} + C$$

(c) The CAS verifies our guesses. Now

$$\frac{1}{(x+a)(x+b)} = \frac{A}{x+a} + \frac{B}{x+b} \Rightarrow 1 = A(x+b) + B(x+a)$$

Setting $x = -b$ gives $B = 1/(a-b)$ and setting $x = -a$ gives $A = 1/(b-a)$. So

$$\int \frac{1}{(x+a)(x+b)} dx = \int \left[\frac{1/(b-a)}{x+a} + \frac{1/(a-b)}{x+b} \right] dx = \frac{\ln|x+a|}{b-a} + \frac{\ln|x+b|}{a-b} + C$$

and our guess for $a \neq b$ is correct.

If $a = b$, then $\frac{1}{(x+a)(x+b)} = \frac{1}{(x+a)^2} = (x+a)^{-2}$. Letting $u = x+a \Rightarrow du = dx$, we have

$$\int (x+a)^{-2} dx = \int u^{-2} du = -\frac{1}{u} + C = -\frac{1}{x+a} + C, \text{ and our guess for } a = b \text{ is also correct.}$$

2. (a) (i) $\int \sin x \cos 2x dx = \frac{\cos x}{2} - \frac{\cos 3x}{6}$
 (ii) $\int \sin 3x \cos 7x dx = \frac{\cos 4x}{8} - \frac{\cos 10x}{20}$
 (iii) $\int \sin 8x \cos 3x dx = -\frac{\cos 11x}{22} - \frac{\cos 5x}{10}$

(b) Looking at the sums and differences of a and b in part (a), we guess that

$$\int \sin ax \cos bx dx = \frac{\cos((a-b)x)}{2(b-a)} - \frac{\cos((a+b)x)}{2(a+b)} + C$$

Note that $\cos((a-b)x) = \cos((b-a)x)$.

(c) The CAS verifies our guess. To integrate directly, we can use Formula 2(a) from Section 8.2.

$$\begin{aligned} \int \sin ax \cos bx dx &= \int \left\{ \frac{1}{2} [\sin(ax-bx) + \sin(ax+bx)] \right\} dx = \frac{1}{2} \int [\sin((a-b)x) + \sin((a+b)x)] dx \\ &= \frac{1}{2} \left[-\frac{\cos((a-b)x)}{b-a} - \frac{\cos((a+b)x)}{a+b} \right] + C = \frac{\cos((a-b)x)}{2(b-a)} - \frac{\cos((a+b)x)}{2(a+b)} + C \end{aligned}$$

Our formula is valid for $a \neq b$.

3. (a) (i) $\int \ln x dx = x \ln x - x$
 (ii) $\int x \ln x dx = \frac{1}{2} x^2 \ln x - \frac{1}{4} x^2$
 (iii) $\int x^2 \ln x dx = \frac{1}{3} x^3 \ln x - \frac{1}{9} x^3$
 (iv) $\int x^3 \ln x dx = \frac{1}{4} x^4 \ln x - \frac{1}{16} x^4$
 (v) $\int x^7 \ln x dx = \frac{1}{8} x^8 \ln x - \frac{1}{64} x^8$

(b) We guess that $\int x^n \ln x dx = \frac{1}{n+1} x^{n+1} \ln x - \frac{1}{(n+1)^2} x^{n+1}$.

(c) Let $u = \ln x$, $dv = x^n dx \Rightarrow du = \frac{dx}{x}$, $v = \frac{1}{n+1} x^{n+1}$.

$$\begin{aligned} \text{Then } \int x^n \ln x dx &= \frac{1}{n+1} x^{n+1} \ln x - \frac{1}{n+1} \int x^n dx \\ &= \frac{1}{n+1} x^{n+1} \ln x - \frac{1}{n+1} \cdot \frac{1}{n+1} x^{n+1}, \end{aligned}$$

which verifies our guess. We must have $n+1 \neq 0 \Leftrightarrow n \neq -1$.

4. (a) (i) $\int x e^x dx = e^x(x - 1)$
 (ii) $\int x^2 e^x dx = e^x(x^2 - 2x + 2)$
 (iii) $\int x^3 e^x dx = e^x(x^3 - 3x^2 + 6x - 6)$
 (iv) $\int x^4 e^x dx = e^x(x^4 - 4x^3 + 12x^2 - 24x + 24)$
 (v) $\int x^5 e^x dx = e^x(x^5 - 5x^4 + 20x^3 - 60x^2 + 120x - 120)$

(b) Notice from part (a) that we can write

$$\int x^4 e^x dx = e^x(x^4 - 4x^3 + 4 \cdot 3x^2 - 4 \cdot 3 \cdot 2x + 4 \cdot 3 \cdot 2 \cdot 1)$$

and

$$\int x^5 e^x dx = e^x(x^5 - 5x^4 + 5 \cdot 4x^3 - 5 \cdot 4 \cdot 3x^2 + 5 \cdot 4 \cdot 3 \cdot 2x - 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1)$$

So we guess that

$$\begin{aligned} \int x^6 e^x dx &= e^x(x^6 - 6x^5 + 6 \cdot 5x^4 - 6 \cdot 5 \cdot 4x^3 + 6 \cdot 5 \cdot 4 \cdot 3x^2 - 6 \cdot 5 \cdot 4 \cdot 3 \cdot 2x + 6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1) \\ &= e^x(x^6 - 6x^5 + 30x^4 - 120x^3 + 360x^2 - 720x + 720) \end{aligned}$$

The CAS verifies our guess.

(c) From the results in part (a), as well as our prediction in part (b), we speculate that

$$\begin{aligned} \int x^n e^x dx &= e^x[x^n - nx^{n-1} + n(n-1)x^{n-2} - n(n-1)(n-2)x^{n-3} + \cdots \pm n!x \mp n!] \\ &= e^x \sum_{i=0}^n (-1)^{n-i} \frac{n!}{i!} x^i \end{aligned}$$

(We have reversed the order of the polynomial's terms.)

(d) Let S_n be the statement that $\int x^n e^x dx = e^x \sum_{i=0}^n (-1)^{n-i} \frac{n!}{i!} x^i$.

S_1 is true by part (a)(i). Suppose S_k is true for some k , and consider S_{k+1} . Integrating by parts with $u = x^{k+1}$, $dv = e^x dx \Rightarrow du = (k+1)x^k dx$, $v = e^x$, we get

$$\begin{aligned} \int x^{k+1} e^x dx &= x^{k+1} e^x - (k+1) \int x^k e^x dx \\ &= x^{k+1} e^x - (k+1) \left[e^x \sum_{i=0}^k (-1)^{k-i} \frac{k!}{i!} x^i \right] \\ &= e^x \left[x^{k+1} - (k+1) \sum_{i=0}^k (-1)^{k-i} \frac{k!}{i!} x^i \right] \\ &= e^x \left[x^{k+1} + \sum_{i=0}^k (-1)^{k-i+1} \frac{(k+1)k!}{i!} x^i \right] \\ &= e^x \sum_{i=0}^{k+1} (-1)^{(k+1)-i} \frac{(k+1)!}{i!} x^i \end{aligned}$$

This verifies S_n for $n = k + 1$. Thus, by mathematical induction, S_n is true for all n , where n is a positive integer.

8.7 Approximate Integration

1. (a) $\Delta x = (b - a)/n = (4 - 0)/2 = 2$

$$L_2 = \sum_{i=1}^2 f(x_{i-1}) \Delta x = f(x_0) \cdot 2 + f(x_1) \cdot 2 = 2[f(0) + f(2)] = 2(0.5 + 2.5) = 6$$

$$R_2 = \sum_{i=1}^2 f(x_i) \Delta x = f(x_1) \cdot 2 + f(x_2) \cdot 2 = 2[f(2) + f(4)] = 2(2.5 + 3.5) = 12$$

$$M_2 = \sum_{i=1}^2 f(\bar{x}_i) \Delta x = f(\bar{x}_1) \cdot 2 + f(\bar{x}_2) \cdot 2 = 2[f(1) + f(3)] \approx 2(1.6 + 3.2) = 9.6$$

L_2 is an underestimate, since the area under the small rectangles is less than the area under the curve, and R_2 is an overestimate, since the area under the large rectangles is greater than the area under the curve. It appears that M_2 is an overestimate, though it is fairly close to I . See the solution to Exercise 45 for a proof of the fact that if f is concave down on $[a, b]$, then the Midpoint Rule is an overestimate of $\int_a^b f(x) dx$.

(c) $T_2 = (\frac{1}{2} \Delta x)[f(x_0) + 2f(x_1) + f(x_2)] = \frac{2}{2}[f(0) + 2f(2) + f(4)] = 0.5 + 2(2.5) + 3.5 = 9$.

This approximation is an underestimate, since the graph is concave down. Thus, $T_2 = 9 < I$. See the solution to Exercise 45 for a general proof of this conclusion.

(d) For any n , we will have $L_n < T_n < I < M_n < R_n$.

2.

The diagram shows that $L_4 > T_4 > \int_0^2 f(x) dx > R_4$, and it appears that M_4 is a bit less than $\int_0^2 f(x) dx$. In fact, for any function that is concave upward, it can be shown that

$$L_n > T_n > \int_0^2 f(x) dx > M_n > R_n.$$

(a) Since $0.9540 > 0.8675 > 0.8632 > 0.7811$, it follows that

$$L_n = 0.9540, T_n = 0.8675, M_n = 0.8632, \text{ and } R_n = 0.7811.$$

(b) Since $M_n < \int_0^2 f(x) dx < T_n$, we have

$$0.8632 < \int_0^2 f(x) dx < 0.8675.$$

3. $f(x) = \cos(x^2)$, $\Delta x = \frac{1-0}{4} = \frac{1}{4}$

(a) $T_4 = \frac{1}{4} \cdot \frac{1}{2} [f(0) + 2f(\frac{1}{4}) + 2f(\frac{3}{4}) + f(1)] \approx 0.895759$

(b) $M_4 = \frac{1}{4} [f(\frac{1}{8}) + f(\frac{3}{8}) + f(\frac{5}{8}) + f(\frac{7}{8})] \approx 0.908907$

The graph shows that f is concave down on $[0, 1]$. So T_4 is an underestimate and M_4 is an overestimate. We can conclude that

$$0.895759 < \int_0^1 \cos(x^2) dx < 0.908907.$$

4.

(a) Since f is increasing on $[0, 1]$, L_2 will underestimate I (since the area of the darkest rectangle is less than the area under the curve), and R_2 will overestimate I . Since f is concave upward on $[0, 1]$, M_2 will underestimate I and T_2 will overestimate I (the area under the straight line segments is greater than the area under the curve).

(b) For any n , we will have $L_n < M_n < I < T_n < R_n$.

$$(c) L_5 = \sum_{i=1}^5 f(x_{i-1}) \Delta x = \frac{1}{5} [f(0.0) + f(0.2) + f(0.4) + f(0.6) + f(0.8)] \approx 0.1187$$

$$R_5 = \sum_{i=1}^5 f(x_i) \Delta x = \frac{1}{5} [f(0.2) + f(0.4) + f(0.6) + f(0.8) + f(1)] \approx 0.2146$$

$$M_5 = \sum_{i=1}^5 f(\bar{x}_i) \Delta x = \frac{1}{5} [f(0.1) + f(0.3) + f(0.5) + f(0.7) + f(0.9)] \approx 0.1622$$

$$T_5 = \left(\frac{1}{2} \Delta x\right) [f(0) + 2f(0.2) + 2f(0.4) + 2f(0.6) + 2f(0.8) + f(1)] \approx 0.1666$$

From the graph, it appears that the Midpoint Rule gives the best approximation. (This is in fact the case, since $I \approx 0.16371405$.)

$$5. f(x) = x^2 \sin x, \Delta x = \frac{b-a}{n} = \frac{\pi-0}{8} = \frac{\pi}{8}$$

$$(a) M_8 = \frac{\pi}{8} \left[f\left(\frac{\pi}{16}\right) + f\left(\frac{3\pi}{16}\right) + f\left(\frac{5\pi}{16}\right) + \cdots + f\left(\frac{15\pi}{16}\right) \right] \approx 5.932957$$

$$(b) S_8 = \frac{\pi}{8 \cdot 3} \left[f(0) + 4f\left(\frac{\pi}{8}\right) + 2f\left(\frac{2\pi}{8}\right) + 4f\left(\frac{3\pi}{8}\right) + 2f\left(\frac{4\pi}{8}\right) + 4f\left(\frac{5\pi}{8}\right) + 2f\left(\frac{6\pi}{8}\right) + 4f\left(\frac{7\pi}{8}\right) + f(\pi) \right] \\ \approx 5.869247$$

$$\text{Actual: } \int_0^\pi x^2 \sin x \, dx \stackrel{84}{=} [-x^2 \cos x]_0^\pi + 2 \int_0^\pi x \cos x \, dx \stackrel{83}{=} [-\pi^2(-1) - 0] + 2[\cos x + x \sin x]_0^\pi \\ = \pi^2 + 2[(-1 + 0) - (1 + 0)] = \pi^2 - 4 \approx 5.869604$$

$$\text{Errors: } E_M = \text{actual} - M_8 = \int_0^\pi x^2 \sin x \, dx - M_8 \approx -0.063353$$

$$E_S = \text{actual} - S_8 = \int_0^\pi x^2 \sin x \, dx - S_8 \approx 0.000357$$

$$6. f(x) = e^{-\sqrt{x}}, \Delta x = \frac{b-a}{n} = \frac{1-0}{6} = \frac{1}{6}$$

$$(a) M_6 = \frac{1}{6} \left[f\left(\frac{1}{12}\right) + f\left(\frac{3}{12}\right) + f\left(\frac{5}{12}\right) + f\left(\frac{7}{12}\right) + f\left(\frac{9}{12}\right) + f\left(\frac{11}{12}\right) \right] \approx 0.525100$$

$$(b) S_6 = \frac{1}{6 \cdot 3} \left[f(0) + 4f\left(\frac{1}{6}\right) + 2f\left(\frac{2}{6}\right) + 4f\left(\frac{3}{6}\right) + 2f\left(\frac{4}{6}\right) + 4f\left(\frac{5}{6}\right) + f(1) \right] \approx 0.533979$$

$$\text{Actual: } \int_0^1 e^{-\sqrt{x}} \, dx = \int_0^1 e^u 2u \, du \quad [u = -\sqrt{x}, u^2 = x, 2u \, du = dx] \\ \stackrel{96}{=} 2[(u-1)e^u]_0^{-1} = 2[-2e^{-1} - (-1e^0)] = 2 - 4e^{-1} \approx 0.528482$$

$$\text{Errors: } E_M = \text{actual} - M_6 = \int_0^1 e^{-\sqrt{x}} \, dx - M_6 \approx 0.003382$$

$$E_S = \text{actual} - S_6 = \int_0^1 e^{-\sqrt{x}} \, dx - S_6 \approx -0.005497$$

$$7. f(x) = \sqrt[4]{1+x^2}, \Delta x = \frac{2-0}{8} = \frac{1}{4}$$

$$(a) T_8 = \frac{1}{4 \cdot 2} \left[f(0) + 2f\left(\frac{1}{4}\right) + 2f\left(\frac{1}{2}\right) + \cdots + 2f\left(\frac{3}{2}\right) + 2f\left(\frac{7}{4}\right) + f(2) \right] \approx 2.413790$$

$$(b) M_8 = \frac{1}{4} \left[f\left(\frac{1}{8}\right) + f\left(\frac{3}{8}\right) + \cdots + f\left(\frac{13}{8}\right) + f\left(\frac{15}{8}\right) \right] \approx 2.411453$$

$$(c) S_8 = \frac{1}{4 \cdot 3} \left[f(0) + 4f\left(\frac{1}{4}\right) + 2f\left(\frac{1}{2}\right) + 4f\left(\frac{3}{4}\right) + 2f(1) + 4f\left(\frac{5}{4}\right) + 2f\left(\frac{3}{2}\right) + 4f\left(\frac{7}{4}\right) + f(2) \right] \approx 2.412232$$

$$8. f(x) = \sin(x^2), \Delta x = \frac{\frac{1}{2} - 0}{4} = \frac{1}{8}$$

$$(a) T_4 = \frac{1}{8 \cdot 2} [f(0) + 2f(\frac{1}{8}) + 2f(\frac{2}{8}) + 2f(\frac{3}{8}) + f(\frac{1}{2})] \approx 0.042743$$

$$(b) M_4 = \frac{1}{8} [f(\frac{1}{16}) + f(\frac{3}{16}) + f(\frac{5}{16}) + f(\frac{7}{16})] \approx 0.040850$$

$$(c) S_4 = \frac{1}{8 \cdot 3} [f(0) + 4f(\frac{1}{8}) + 2f(\frac{2}{8}) + 4f(\frac{3}{8}) + f(\frac{1}{2})] \approx 0.041478$$

$$9. f(x) = \frac{\ln x}{1+x}, \Delta x = \frac{2-1}{10} = \frac{1}{10}$$

$$(a) T_{10} = \frac{1}{10 \cdot 2} [f(1) + 2f(1.1) + 2f(1.2) + \cdots + 2f(1.8) + 2f(1.9) + f(2)] \approx 0.146879$$

$$(b) M_{10} = \frac{1}{10} [f(1.05) + f(1.15) + \cdots + f(1.85) + f(1.95)] \approx 0.147391$$

$$(c) S_{10} = \frac{1}{10 \cdot 3} [f(1) + 4f(1.1) + 2f(1.2) + 4f(1.3) + 2f(1.4) + 4f(1.5) + 2f(1.6) + 4f(1.7) + 2f(1.8) + 4f(1.9) + f(2)] \approx 0.147219$$

$$10. f(t) = \frac{1}{1+t^2+t^4}, \Delta t = \frac{3-0}{6} = \frac{1}{2}$$

$$(a) T_6 = \frac{1}{2 \cdot 2} [f(0) + 2f(\frac{1}{2}) + 2f(1) + 2f(\frac{3}{2}) + 2f(2) + 2f(\frac{5}{2}) + f(3)] \approx 0.895122$$

$$(b) M_6 = \frac{1}{2} [f(\frac{1}{4}) + f(\frac{3}{4}) + f(\frac{5}{4}) + f(\frac{7}{4}) + f(\frac{9}{4}) + f(\frac{11}{4})] \approx 0.895478$$

$$(c) S_6 = \frac{1}{2 \cdot 3} [f(0) + 4f(\frac{1}{2}) + 2f(1) + 4f(\frac{3}{2}) + 2f(2) + 4f(\frac{5}{2}) + f(3)] \approx 0.898014$$

$$11. f(t) = \sin(e^{t/2}), \Delta t = \frac{\frac{1}{2} - 0}{8} = \frac{1}{16}$$

$$(a) T_8 = \frac{1}{16 \cdot 2} [f(0) + 2f(\frac{1}{16}) + 2f(\frac{2}{16}) + \cdots + 2f(\frac{7}{16}) + f(\frac{1}{2})] \approx 0.451948$$

$$(b) M_8 = \frac{1}{16} [f(\frac{1}{32}) + f(\frac{3}{32}) + f(\frac{5}{32}) + \cdots + f(\frac{13}{32}) + f(\frac{15}{32})] \approx 0.451991$$

$$(c) S_8 = \frac{1}{16 \cdot 3} [f(0) + 4f(\frac{1}{16}) + 2f(\frac{2}{16}) + \cdots + 4f(\frac{7}{16}) + f(\frac{1}{2})] \approx 0.451976$$

$$12. f(x) = \sqrt{1+\sqrt{x}}, \Delta x = \frac{4-0}{8} = \frac{1}{2}$$

$$(a) T_8 = \frac{1}{2 \cdot 2} [f(0) + 2f(\frac{1}{2}) + 2f(1) + \cdots + 2f(3) + 2f(\frac{7}{2}) + f(4)] \approx 6.042985$$

$$(b) M_8 = \frac{1}{2} [f(\frac{1}{4}) + f(\frac{3}{4}) + \cdots + f(\frac{13}{4}) + f(\frac{15}{4})] \approx 6.084778$$

$$(c) S_8 = \frac{1}{2 \cdot 3} [f(0) + 4f(\frac{1}{2}) + 2f(1) + 4f(\frac{3}{2}) + 2f(2) + 4f(\frac{5}{2}) + 2f(3) + 4f(\frac{7}{2}) + f(4)] \approx 6.061678$$

$$13. f(x) = e^{1/x}, \Delta x = \frac{2-1}{4} = \frac{1}{4}$$

$$(a) T_4 = \frac{1}{4 \cdot 2} [f(1) + 2f(1.25) + 2f(1.5) + 2f(1.75) + f(2)] \approx 2.031893$$

$$(b) M_4 = \frac{1}{4} [f(1.125) + f(1.375) + f(1.625) + f(1.875)] \approx 2.014207$$

$$(c) S_4 = \frac{1}{4 \cdot 3} [f(1) + 4f(1.25) + 2f(1.5) + 4f(1.75) + f(2)] \approx 2.020651$$

$$14. f(x) = \sqrt{x} \sin x, \Delta x = \frac{4-0}{8} = \frac{1}{2}$$

$$(a) T_8 = \frac{1}{2 \cdot 2} \{f(0) + 2[f(\frac{1}{2}) + f(1) + f(\frac{3}{2}) + f(2) + f(\frac{5}{2}) + f(3) + f(\frac{7}{2})] + f(4)\} \approx 1.732865$$

$$(b) M_8 = \frac{1}{2} [f(\frac{1}{4}) + f(\frac{3}{4}) + f(\frac{5}{4}) + f(\frac{7}{4}) + \cdots + f(\frac{13}{4}) + f(\frac{15}{4})] \approx 1.787427$$

$$(c) S_8 = \frac{1}{2 \cdot 3} [f(0) + 4f(\frac{1}{2}) + 2f(1) + 4f(\frac{3}{2}) + 2f(2) + 4f(\frac{5}{2}) + 2f(3) + 4f(\frac{7}{2}) + f(4)] \approx 1.772142$$

$$15. f(x) = \frac{\cos x}{x}, \Delta x = \frac{5-1}{8} = \frac{1}{2}$$

$$(a) T_8 = \frac{1}{2} \cdot \frac{1}{2} [f(1) + 2f(\frac{3}{2}) + 2f(2) + \cdots + 2f(4) + 2f(\frac{9}{2}) + f(5)] \approx -0.495333$$

$$(b) M_8 = \frac{1}{2} [f(\frac{5}{4}) + f(\frac{7}{4}) + f(\frac{9}{4}) + f(\frac{11}{4}) + f(\frac{13}{4}) + f(\frac{15}{4}) + f(\frac{17}{4}) + f(\frac{19}{4})] \approx -0.543321$$

$$(c) S_8 = \frac{1}{2} \cdot \frac{1}{2} [f(1) + 4f(\frac{3}{2}) + 2f(2) + 4f(\frac{5}{2}) + 2f(3) + 4f(\frac{7}{2}) + 2f(4) + 4f(\frac{9}{2}) + f(5)] \\ \approx -0.526123$$

$$16. f(x) = \ln(x^3 + 2), \Delta x = \frac{6-4}{10} = \frac{1}{5}$$

$$(a) T_{10} = \frac{1}{5} \cdot \frac{1}{2} [f(4) + 2f(4.2) + 2f(4.4) + \cdots + 2f(5.6) + 2f(5.8) + f(6)] \approx 9.649753$$

$$(b) M_{10} = \frac{1}{5} [f(4.1) + f(4.3) + \cdots + f(5.7) + f(5.9)] \approx 9.650912$$

$$(c) S_{10} = \frac{1}{5} \cdot \frac{1}{3} [f(4) + 4f(4.2) + 2f(4.4) + 4f(4.6) + 2f(4.8) + 4f(5) \\ + 2f(5.2) + 4f(5.4) + 2f(5.6) + 4f(5.8) + f(6)] \\ \approx 9.650526$$

$$17. f(y) = \frac{1}{1+y^5}, \Delta y = \frac{3-0}{6} = \frac{1}{2}$$

$$(a) T_6 = \frac{1}{2} \cdot \frac{1}{2} [f(0) + 2f(\frac{1}{2}) + 2f(\frac{2}{2}) + 2f(\frac{3}{2}) + 2f(\frac{4}{2}) + 2f(\frac{5}{2}) + f(3)] \approx 1.064275$$

$$(b) M_6 = \frac{1}{2} [f(\frac{1}{4}) + f(\frac{3}{4}) + f(\frac{5}{4}) + f(\frac{7}{4}) + f(\frac{9}{4}) + f(\frac{11}{4})] \approx 1.067416$$

$$(c) S_6 = \frac{1}{2} \cdot \frac{1}{3} [f(0) + 4f(\frac{1}{2}) + 2f(\frac{2}{2}) + 4f(\frac{3}{2}) + 2f(\frac{4}{2}) + 4f(\frac{5}{2}) + f(3)] \approx 1.074915$$

$$18. f(x) = \frac{e^x}{x}, \Delta x = \frac{4-2}{10} = \frac{1}{5}$$

$$(a) T_{10} = \frac{1}{5} \cdot \frac{1}{2} \{f(2) + 2[f(2.2) + f(2.4) + f(2.6) + \cdots + f(3.8)] + f(4)\} \approx 14.704592$$

$$(b) M_{10} = \frac{1}{5} [f(2.1) + f(2.3) + f(2.5) + f(2.7) + \cdots + f(3.7) + f(3.9)] \approx 14.662669$$

$$(c) S_{10} = \frac{1}{5} \cdot \frac{1}{3} [f(2) + 4f(2.2) + 2f(2.4) + 4f(2.6) + \cdots + 2f(3.6) + 4f(3.8) + f(4)] \approx 14.676696$$

$$19. f(x) = e^{-x^2}, \Delta x = \frac{2-0}{10} = \frac{1}{5}$$

$$(a) T_{10} = \frac{1}{5} \cdot \frac{1}{2} \{f(0) + 2[f(0.2) + f(0.4) + \cdots + f(1.8)] + f(2)\} \approx 0.881839$$

$$M_{10} = \frac{1}{5} [f(0.1) + f(0.3) + f(0.5) + \cdots + f(1.7) + f(1.9)] \approx 0.882202$$

$$(b) f(x) = e^{-x^2}, f'(x) = -2xe^{-x^2}, f''(x) = (4x^2 - 2)e^{-x^2}, f'''(x) = 4x(3 - 2x^2)e^{-x^2}.$$

$$f'''(x) = 0 \Leftrightarrow x = 0 \text{ or } x = \pm\sqrt{\frac{3}{2}}. \text{ So to find the maximum value of } |f''(x)| \text{ on } [0, 2], \text{ we need only}$$

$$\text{consider its values at } x = 0, x = 2, \text{ and } x = \sqrt{\frac{3}{2}}. |f''(0)| = 2, |f''(2)| \approx 0.2564 \text{ and } \left|f''\left(\sqrt{\frac{3}{2}}\right)\right| \approx 0.8925.$$

$$\text{Thus, taking } K = 2, a = 0, b = 2, \text{ and } n = 10 \text{ in Theorem 3, we get } |E_T| \leq 2 \cdot 2^3 / (12 \cdot 10^2) = \frac{1}{75} = 0.01\bar{3}, \\ \text{and } |E_M| \leq |E_T|/2 \leq 0.00\bar{6}.$$

$$(c) \text{ Take } K = 2 \text{ [as in part (b)] in Theorem 3. } |E_T| \leq \frac{K(b-a)^3}{12n^2} \leq 10^{-5} \Leftrightarrow \frac{2(2-0)^3}{12n^2} \leq 10^{-5} \Leftrightarrow$$

$$\frac{3}{4}n^2 \geq 10^5 \Leftrightarrow n \geq 365.1 \dots \Leftrightarrow n \geq 366. \text{ Take } n = 366 \text{ for } T_n. \text{ For } E_M, \text{ again take } K = 2 \text{ in}$$

$$\text{Theorem 3 to get } |E_M| \leq 10^{-5} \Leftrightarrow \frac{3}{2}n^2 \geq 10^5 \Leftrightarrow n \geq 258.2 \Rightarrow n \geq 259. \text{ Take } n = 259 \text{ for } M_n.$$

$$20. (a) T_8 = \frac{1}{8} \cdot \frac{1}{2} \{f(0) + 2[f(\frac{1}{8}) + f(\frac{2}{8}) + \cdots + f(\frac{7}{8})] + f(1)\} \approx 0.902333$$

$$M_8 = \frac{1}{8} [f(\frac{1}{16}) + f(\frac{3}{16}) + f(\frac{5}{16}) + \cdots + f(\frac{15}{16})] = 0.905620$$

(b) $f(x) = \cos(x^2)$, $f'(x) = -2x \sin(x^2)$, $f''(x) = -2 \sin(x^2) - 4x^2 \cos(x^2)$. For $0 \leq x \leq 1$, $\sin$ and $\cos$ are positive, so $|f''(x)| = 2 \sin(x^2) + 4x^2 \cos(x^2) \leq 2 \cdot 1 + 4 \cdot 1 \cdot 1 = 6$ since $\sin(x^2) \leq 1$ and $\cos(x^2) \leq 1$ for all x , and $x^2 \leq 1$ for $0 \leq x \leq 1$. So for $n = 8$, we take $K = 6$, $a = 0$, and $b = 1$ in Theorem 3, to get $|E_T| \leq 6 \cdot 1^3 / (12 \cdot 8^2) = \frac{1}{128} = 0.0078125$ and $|E_M| \leq \frac{1}{256} = 0.00390625$. [A better estimate is obtained by noting from a graph of f'' that $|f''(x)| \leq 4$ for $0 \leq x \leq 1$.]

(c) Using $K = 6$ as in part (b), we have $|E_T| \leq 6 \cdot 1^3 / (12n^2) = 1 / (2n^2) \leq 10^{-5} \Rightarrow 2n^2 \geq 10^5 \Rightarrow n \geq \sqrt{\frac{1}{2} \cdot 10^5}$ or $n \geq 224$. To guarantee that $|E_M| \leq 0.00001$, we need $6 \cdot 1^3 / (24n^2) \leq 10^{-5} \Rightarrow 4n^2 \geq 10^5 \Rightarrow n \geq \sqrt{\frac{1}{4} \cdot 10^5}$ or $n \geq 159$.

21. (a) $T_{10} = \frac{1}{10 \cdot 2} \{f(0) + 2[f(0.1) + f(0.2) + \cdots + f(0.9)] + f(1)\} \approx 1.71971349$
 $S_{10} = \frac{1}{10 \cdot 3} [f(0) + 4f(0.1) + 2f(0.2) + 4f(0.3) + \cdots + 4f(0.9) + f(1)] \approx 1.71828278$
 Since $I = \int_0^1 e^x dx = [e^x]_0^1 = e - 1 \approx 1.71828183$, $E_T = I - T_{10} \approx -0.00143166$ and $E_S = I - S_{10} \approx -0.00000095$.

(b) $f(x) = e^x \Rightarrow f''(x) = e^x \leq e$ for $0 \leq x \leq 1$. Taking $K = e$, $a = 0$, $b = 1$, and $n = 10$ in Theorem 3, we get $|E_T| \leq e(1)^3 / (12 \cdot 10^2) \approx 0.002265 > 0.00143166$ [actual $|E_T|$ from (a)]. $f^{(4)}(x) = e^x < e$ for $0 \leq x \leq 1$. Using Theorem 4, we have $|E_S| \leq e(1)^5 / (180 \cdot 10^4) \approx 0.0000015 > 0.00000095$ [actual $|E_S|$ from (a)]. We see that the actual errors are about two-thirds the size of the error estimates.

(c) From part (b), we take $K = e$ to get $|E_T| \leq \frac{K(b-a)^3}{12n^2} \leq 0.00001 \Rightarrow n^2 \geq \frac{e(1^3)}{12(0.00001)} \Rightarrow n \geq 150.5$. Take $n = 151$ for T_n . Now $|E_M| \leq \frac{K(b-a)^3}{24n^2} \leq 0.00001 \Rightarrow n \geq 106.4$. Take $n = 107$ for M_n . Finally, $|E_S| \leq \frac{K(b-a)^5}{180n^4} \leq 0.00001 \Rightarrow n^4 \geq \frac{e(1^5)}{180(0.00001)} \Rightarrow n \geq 6.23$. Take $n = 8$ for S_n (since n has to be even for Simpson's Rule).

22. From Example 7(b), we take $K = 76e$ to get $|E_S| \leq 76e(1)^5 / (180n^4) \leq 0.00001 \Rightarrow n^4 \geq 76e / [180(0.00001)] \Rightarrow n \geq 18.4$. Take $n = 20$ (since n must be even).

23. (a) Using a CAS, we differentiate $f(x) = e^{\cos x}$ twice, and find that $f''(x) = e^{\cos x} (\sin^2 x - \cos x)$. From the graph, we see that the maximum value of $|f''(x)|$ occurs at the endpoints of the interval $[0, 2\pi]$. Since $f''(0) = -e$, we can use $K = e$ or $K = 2.8$.

(b) A CAS gives $M_{10} \approx 7.954926518$. (In Maple, use student [middlesum].)

(c) Using Theorem 3 for the Midpoint Rule, with $K = e$, we get $|E_M| \leq \frac{e(2\pi - 0)^3}{24 \cdot 10^2} \approx 0.280945995$. With

$$K = 2.8, \text{ we get } |E_M| \leq \frac{2.8(2\pi - 0)^3}{24 \cdot 10^2} = 0.289391916.$$

(d) A CAS gives $I \approx 7.954926521$.

(e) The actual error is only about 3×10^{-9} , much less than the estimate in part (c).

- (f) We use the CAS to differentiate twice more, and then graph

$$f^{(4)}(x) = e^{\cos x} (\sin^4 x - 6 \sin^2 x \cos x + 3 - 7 \sin^2 x + \cos x).$$

From the graph, we see that the maximum value of $|f^{(4)}(x)|$ occurs at the endpoints of the interval $[0, 2\pi]$. Since $f^{(4)}(0) = 4e$, we can use $K = 4e$ or $K = 10.9$.

- (g) A CAS gives
- $S_{10} \approx 7.953789422$
- . (In Maple, use
- `student [simpson]`
- .)

- (h) Using Theorem 4 with
- $K = 4e$
- , we get
- $|E_S| \leq \frac{4e(2\pi - 0)^5}{180 \cdot 10^4} \approx 0.059153618$
- . With
- $K = 10.9$
- , we get

$$|E_S| \leq \frac{10.9(2\pi - 0)^5}{180 \cdot 10^4} \approx 0.059299814.$$

- (i) The actual error is about
- $7.954926521 - 7.953789422 \approx 0.00114$
- . This is quite a bit smaller than the estimate in part (h), though the difference is not nearly as great as it was in the case of the Midpoint Rule.

- (j) To ensure that
- $|E_S| \leq 0.0001$
- , we use Theorem 4:
- $|E_S| \leq \frac{4e(2\pi)^5}{180 \cdot n^4} \leq 0.0001 \Rightarrow \frac{4e(2\pi)^5}{180 \cdot 0.0001} \leq n^4 \Rightarrow n^4 \geq 5,915,362 \Leftrightarrow n \geq 49.3$
- . So we must take
- $n \geq 50$
- to ensure that
- $|I - S_n| \leq 0.0001$
- . (
- $K = 10.9$
- leads to the same value of
- n
- .)

24. (a) Using the CAS, we differentiate
- $f(x) = \sqrt{4 - x^3}$
- twice,

$$\text{and find that } f''(x) = -\frac{9x^4}{4(4 - x^3)^{3/2}} - \frac{3x}{(4 - x^3)^{1/2}}.$$

From the graph, we see that $|f''(x)| < 2.2$ on $[-1, 1]$.

- (b) A CAS gives
- $M_{10} \approx 3.995804152$
- . (In Maple, use
- `student [middlesum]`
- .)

- (c) Using Theorem 3 for the Midpoint Rule, with
- $K = 2.2$
- , we get
- $|E_M| \leq \frac{2.2[1 - (-1)]^3}{24 \cdot 10^2} \approx 0.00733$
- .

- (d) A CAS gives
- $I \approx 3.995487677$
- .

- (e) The actual error is about
- -0.0003165
- , much less than the estimate in part (c).

- (f) We use the CAS to differentiate twice more, and then graph

$$f^{(4)}(x) = \frac{9}{16} \frac{x^2(x^6 - 224x^3 - 1280)}{(4 - x^3)^{7/2}}.$$

From the graph, we see that $|f^{(4)}(x)| < 18.1$ on $[-1, 1]$.

- (g) A CAS gives
- $S_{10} \approx 3.995449790$
- . (In Maple, use
- `student [simpson]`
- .)

- (h) Using Theorem 4 with
- $K = 18.1$
- , we get
- $|E_S| \leq \frac{18.1[1 - (-1)]^5}{180 \cdot 10^4} \approx 0.000322$
- .

- (i) The actual error is about
- $3.995487677 - 3.995449790 \approx 0.0000379$
- . This is quite a bit smaller than the estimate in part (h).

(j) To ensure that $|E_S| \leq 0.0001$, we use Theorem 4: $|E_S| \leq \frac{18.1(2)^5}{180 \cdot n^4} \leq 0.0001 \Rightarrow \frac{18.1(2)^5}{180 \cdot 0.0001} \leq n^4 \Rightarrow n^4 \geq 32,178 \Rightarrow n \geq 13.4$. So we must take $n \geq 14$ to ensure that $|I - S_n| \leq 0.0001$.

25. $I = \int_0^1 x^3 dx = \left[\frac{1}{4}x^4\right]_0^1 = 0.25$. $f(x) = x^3$.

$n = 4$: $L_4 = \frac{1}{4} \left[0^3 + \left(\frac{1}{4}\right)^3 + \left(\frac{2}{4}\right)^3 + \left(\frac{3}{4}\right)^3 \right] = 0.140625$

$R_4 = \frac{1}{4} \left[\left(\frac{1}{4}\right)^3 + \left(\frac{2}{4}\right)^3 + \left(\frac{3}{4}\right)^3 + 1^3 \right] = 0.390625$

$T_4 = \frac{1}{4 \cdot 2} \left[0^3 + 2\left(\frac{1}{4}\right)^3 + 2\left(\frac{2}{4}\right)^3 + 2\left(\frac{3}{4}\right)^3 + 1^3 \right] = 0.265625$,

$M_4 = \frac{1}{4} \left[\left(\frac{1}{8}\right)^3 + \left(\frac{3}{8}\right)^3 + \left(\frac{5}{8}\right)^3 + \left(\frac{7}{8}\right)^3 \right] = 0.2421875$,

$E_L = I - L_4 = \frac{1}{4} - 0.140625 = 0.109375$, $E_R = \frac{1}{4} - 0.390625 = -0.140625$,

$E_T = \frac{1}{4} - 0.265625 = -0.015625$, $E_M = \frac{1}{4} - 0.2421875 = 0.0078125$

$n = 8$: $L_8 = \frac{1}{8} \left[f(0) + f\left(\frac{1}{8}\right) + f\left(\frac{2}{8}\right) + \cdots + f\left(\frac{7}{8}\right) \right] \approx 0.191406$

$R_8 = \frac{1}{8} \left[f\left(\frac{1}{8}\right) + f\left(\frac{2}{8}\right) + \cdots + f\left(\frac{7}{8}\right) + f(1) \right] \approx 0.316406$

$T_8 = \frac{1}{8 \cdot 2} \{ f(0) + 2[f\left(\frac{1}{8}\right) + f\left(\frac{2}{8}\right) + \cdots + f\left(\frac{7}{8}\right)] + f(1) \} \approx 0.253906$

$M_8 = \frac{1}{8} \left[f\left(\frac{1}{16}\right) + f\left(\frac{3}{16}\right) + \cdots + f\left(\frac{13}{16}\right) + f\left(\frac{15}{16}\right) \right] = 0.248047$

$E_L \approx \frac{1}{4} - 0.191406 \approx 0.058594$, $E_R \approx \frac{1}{4} - 0.316406 \approx -0.066406$,

$E_T \approx \frac{1}{4} - 0.253906 \approx -0.003906$, $E_M \approx \frac{1}{4} - 0.248047 \approx 0.001953$.

$n = 16$: $L_{16} = \frac{1}{16} \left[f(0) + f\left(\frac{1}{16}\right) + f\left(\frac{2}{16}\right) + \cdots + f\left(\frac{15}{16}\right) \right] \approx 0.219727$

$R_{16} = \frac{1}{16} \left[f\left(\frac{1}{16}\right) + f\left(\frac{2}{16}\right) + \cdots + f\left(\frac{15}{16}\right) + f(1) \right] \approx 0.282227$

$T_{16} = \frac{1}{16 \cdot 2} \{ f(0) + 2[f\left(\frac{1}{16}\right) + f\left(\frac{2}{16}\right) + \cdots + f\left(\frac{15}{16}\right)] + f(1) \} \approx 0.250977$

$M_{16} = \frac{1}{16} \left[f\left(\frac{1}{32}\right) + f\left(\frac{3}{32}\right) + \cdots + f\left(\frac{31}{32}\right) \right] \approx 0.249512$

$E_L \approx \frac{1}{4} - 0.219727 \approx 0.030273$, $E_R \approx \frac{1}{4} - 0.282227 \approx -0.032227$,

$E_T \approx \frac{1}{4} - 0.250977 \approx -0.000977$, $E_M \approx \frac{1}{4} - 0.249512 \approx 0.000488$.

n	L_n	R_n	T_n	M_n
4	0.140625	0.390625	0.265625	0.242188
8	0.191406	0.316406	0.253906	0.248047
16	0.219727	0.282227	0.250977	0.249512

n	E_L	E_R	E_T	E_M
4	0.109375	-0.140625	-0.015625	0.007813
8	0.058594	-0.066406	-0.003906	0.001953
16	0.030273	-0.032227	-0.000977	0.000488

Observations:

1. E_L and E_R are always opposite in sign, as are E_T and E_M .
2. As n is doubled, E_L and E_R are decreased by about a factor of 2, and E_T and E_M are decreased by a factor of about 4.
3. The Midpoint approximation is about twice as accurate as the Trapezoidal approximation.
4. All the approximations become more accurate as the value of n increases.
5. The Midpoint and Trapezoidal approximations are much more accurate than the endpoint approximations.

$$26. \int_0^2 e^x dx = [e^x]_0^2 = e^2 - 1 \approx 6.389056. \quad f(x) = e^x$$

$$n = 4: \quad \Delta x = (2 - 0)/4 = \frac{1}{2}$$

$$L_4 = \frac{1}{2} [e^0 + e^{1/2} + e^1 + e^{3/2}] \approx 4.924346$$

$$R_4 = \frac{1}{2} [e^{1/2} + e^1 + e^{3/2} + e^2] \approx 8.118874$$

$$T_4 = \frac{1}{2 \cdot 2} [e^0 + 2e^{1/2} + 2e^1 + 2e^{3/2} + e^2] \approx 6.521610$$

$$M_4 = \frac{1}{2} [e^{1/4} + e^{3/4} + e^{5/4} + e^{7/4}] \approx 6.322986.$$

$$E_L \approx 6.389056 - 4.924346 \approx 1.464710, \quad E_R \approx 6.389056 - 8.118874 = -1.729818,$$

$$E_T \approx 6.389056 - 6.521610 \approx -0.132554, \quad E_M \approx 6.389056 - 6.322986 = 0.0660706.$$

$$n = 8: \quad \Delta x = (2 - 0)/8 = \frac{1}{4}$$

$$L_8 = \frac{1}{4} [e^0 + e^{1/4} + e^{1/2} + e^{3/4} + e^1 + e^{5/4} + e^{3/2} + e^{7/4}] \approx 5.623666$$

$$R_8 = \frac{1}{4} [e^{1/4} + e^{1/2} + e^{3/4} + e^1 + e^{5/4} + e^{3/2} + e^{7/4} + e^2] \approx 7.220930$$

$$T_8 = \frac{1}{4 \cdot 2} [e^0 + 2e^{1/4} + 2e^{1/2} + 2e^{3/4} + 2e^1 + 2e^{5/4} + 2e^{3/2} + 2e^{7/4} + e^2] \approx 6.422298$$

$$M_8 = \frac{1}{4} [e^{1/8} + e^{3/8} + e^{5/8} + e^{7/8} + e^{9/8} + e^{11/8} + e^{13/8} + e^{15/8}] \approx 6.372448$$

$$E_L \approx 6.389056 - 5.623666 \approx 0.765390, \quad E_R \approx 6.389056 - 7.220930 \approx -0.831874,$$

$$E_T \approx 6.389056 - 6.422298 \approx -0.033242, \quad E_M \approx 6.389056 - 6.372448 \approx 0.016608.$$

$$n = 16: \quad \Delta x = (2 - 0)/16 = \frac{1}{8}$$

$$L_{16} = \frac{1}{8} [f(0) + f(\frac{1}{8}) + f(\frac{2}{8}) + \cdots + f(\frac{14}{8}) + f(\frac{15}{8})] \approx 5.998057$$

$$R_{16} = \frac{1}{8} [f(\frac{1}{8}) + f(\frac{2}{8}) + f(\frac{3}{8}) + \cdots + f(\frac{15}{8}) + f(2)] \approx 6.796689$$

$$T_{16} = \frac{1}{8 \cdot 2} [f(0) + 2[f(\frac{1}{8}) + f(\frac{2}{8}) + f(\frac{3}{8}) + \cdots + f(\frac{15}{8})] + f(2)] \approx 6.397373$$

$$M_{16} = \frac{1}{8} [f(\frac{1}{16}) + f(\frac{3}{16}) + f(\frac{5}{16}) + \cdots + f(\frac{29}{16}) + f(\frac{31}{16})] \approx 6.384899$$

$$E_L \approx 6.389056 - 5.998057 \approx 0.390999, \quad E_R \approx 6.389056 - 6.796689 \approx -0.407633,$$

$$E_T \approx 6.389056 - 6.397373 \approx -0.008317, \quad E_M \approx 6.389056 - 6.384899 \approx 0.004158.$$

n	E_L	E_R	E_T	E_M
4	1.464710	-1.729818	-0.132554	0.066071
8	0.765390	-0.831874	-0.033242	0.016608
16	0.390999	-0.407633	-0.008317	0.004158

Observations:

1. E_L and E_R are always opposite in sign, as are E_T and E_M .
2. As n is doubled, E_L and E_R are decreased by a factor of about 2, and E_T and E_M are decreased by a factor of about 4.
3. The Midpoint approximation is about twice as accurate as the Trapezoidal approximation.
4. All the approximations become more accurate as the value of n increases.
5. The Midpoint and Trapezoidal approximations are much more accurate than the endpoint approximations.

$$27. \int_1^4 \sqrt{x} \, dx = \left[\frac{2}{3} x^{3/2} \right]_1^4 = \frac{2}{3} (8 - 1) = \frac{14}{3} \approx 4.666667$$

$$n = 6: \quad \Delta x = (4 - 1)/6 = \frac{1}{2}$$

$$T_6 = \frac{1}{2 \cdot 2} [\sqrt{1} + 2\sqrt{1.5} + 2\sqrt{2} + 2\sqrt{2.5} + 2\sqrt{3} + 2\sqrt{3.5} + \sqrt{4}] \approx 4.661488$$

$$M_6 = \frac{1}{2} [\sqrt{1.25} + \sqrt{1.75} + \sqrt{2.25} + \sqrt{2.75} + \sqrt{3.25} + \sqrt{3.75}] \approx 4.669245$$

$$S_6 = \frac{1}{2 \cdot 3} [\sqrt{1} + 4\sqrt{1.5} + 2\sqrt{2} + 4\sqrt{2.5} + 2\sqrt{3} + 4\sqrt{3.5} + \sqrt{4}] \approx 4.666563$$

$$E_T \approx \frac{14}{3} - 4.661488 \approx 0.005178, \quad E_M \approx \frac{14}{3} - 4.669245 \approx -0.002578,$$

$$E_S \approx \frac{14}{3} - 4.666563 \approx 0.000104.$$

$$n = 12: \quad \Delta x = (4 - 1)/12 = \frac{1}{4}$$

$$T_{12} = \frac{1}{4 \cdot 2} (f(1) + 2[f(1.25) + f(1.5) + \cdots + f(3.5) + f(3.75)] + f(4)) \approx 4.665367$$

$$M_{12} = \frac{1}{4} [f(1.125) + f(1.375) + f(1.625) + \cdots + f(3.875)] \approx 4.667316$$

$$S_{12} = \frac{1}{4 \cdot 3} [f(1) + 4f(1.25) + 2f(1.5) + 4f(1.75) + \cdots + 4f(3.75) + f(4)] \approx 4.666659$$

$$E_T \approx \frac{14}{3} - 4.665367 \approx 0.001300, \quad E_M \approx \frac{14}{3} - 4.667316 \approx -0.000649,$$

$$E_S \approx \frac{14}{3} - 4.666659 \approx 0.000007.$$

Note: These errors were computed more precisely and then rounded to six places. That is, they were not computed by comparing the rounded values of T_n , M_n , and S_n with the rounded value of the actual integral.

n	T_n	M_n	S_n
6	4.661488	4.669245	4.666563
12	4.665367	4.667316	4.666659

n	E_T	E_M	E_S
6	0.005178	-0.002578	0.000104
12	0.001300	-0.000649	0.000007

Observations:

1. E_T and E_M are opposite in sign and decrease by a factor of about 4 as n is doubled.
2. The Simpson's approximation is much more accurate than the Midpoint and Trapezoidal approximations, and seems to decrease by a factor of about 16 as n is doubled.

$$28. I = \int_{-1}^2 x e^x \, dx = [x e^x - e^x]_{-1}^2 = e^2 + 2/e \approx 8.124815. \quad f(x) = x e^x.$$

$$n = 6: \quad \Delta x = [2 - (-1)]/6 = \frac{1}{2}$$

$$T_6 = \frac{1}{2 \cdot 2} \{f(-1) + 2[f(-0.5) + f(0) + \cdots + f(1.5)] + f(2)\} \approx 8.583514$$

$$M_6 = \frac{1}{2} [f(-0.75) + f(-0.25) + \cdots + f(1.75)] \approx 7.896632$$

$$S_6 = \frac{1}{2 \cdot 3} [f(-1) + 4f(-0.5) + 2f(0) + 4f(0.5) + 2f(1) + 4f(1.5) + f(2)] \approx 8.136885$$

$$E_T \approx I - 8.583514 \approx -0.458699, \quad E_M \approx I - 7.896632 \approx 0.228183,$$

$$E_S \approx I - 8.136885 \approx -0.012070.$$

$$n = 12: \quad \Delta x = [2 - (-1)]/12 = \frac{1}{4}$$

$$T_{12} = \frac{1}{4 \cdot 2} \{f(-1) + 2[f(-0.75) + f(-0.5) + \cdots + f(1.75)] + f(2)\} \approx 8.240073$$

$$M_{12} = \frac{1}{4} [f(-\frac{7}{8}) + f(-\frac{5}{8}) + \cdots + f(\frac{13}{8}) + f(\frac{15}{8})] \approx 8.067259$$

$$S_{12} = \frac{1}{4 \cdot 3} [f(-1) + 4f(-0.75) + 2f(-0.5) + \cdots + 2f(1.5) + 4f(1.75) + f(2)] \approx 8.125593$$

$$E_T \approx I - 8.240073 \approx -0.115258, E_M \approx I - 8.067259 \approx 0.057556,$$

$$E_S \approx I - 8.125593 \approx -0.000778$$

n	T_n	M_n	S_n
6	8.583514	7.896632	8.136885
12	8.240073	8.067259	8.125593

n	E_T	E_M	E_S
6	-0.458699	0.228183	-0.012070
12	-0.115258	0.057556	-0.000778

Observations:

1. E_T and E_M are opposite in sign and decrease by a factor of about 4 as n is doubled.
2. The Simpson's approximation is much more accurate than the Midpoint and Trapezoidal approximations, and seems to decrease by a factor of about 16 as n is doubled.

29. $\Delta x = (4 - 0) / 4 = 1$

(a) $T_4 = \frac{1}{2}[f(0) + 2f(1) + 2f(2) + 2f(3) + f(4)] \approx \frac{1}{2}[0 + 2(3) + 2(5) + 2(3) + 1] = 11.5$

(b) $M_4 = 1 \cdot [f(0.5) + f(1.5) + f(2.5) + f(3.5)] \approx 1 + 4.5 + 4.5 + 2 = 12$

(c) $S_4 = \frac{1}{3}[f(0) + 4f(1) + 2f(2) + 4f(3) + f(4)] \approx \frac{1}{3}[0 + 4(3) + 2(5) + 4(3) + 1] = 11.\bar{6}$

30. If x = distance from left end of pool and $w = w(x)$ = width at x , then Simpson's Rule with $n = 8$ and $\Delta x = 2$ gives Area = $\int_0^{16} w \, dx \approx \frac{2}{3}[0 + 4(6.2) + 2(7.2) + 4(6.8) + 2(5.6) + 4(5.0) + 2(4.8) + 4(4.8) + 0] \approx 84 \text{ m}^2$.

31. (a) We are given the function values at the endpoints of 8 intervals of length 0.4, so we'll use the Midpoint Rule with $n = 8/2 = 4$ and $\Delta x = (3.2 - 0)/4 = 0.8$.

$$\begin{aligned} \int_0^{3.2} f(x) \, dx &\approx M_4 = 0.8[f(0.4) + f(1.2) + f(2.0) + f(2.8)] \\ &= 0.8[6.5 + 6.4 + 7.6 + 8.8] \\ &= 0.8(29.3) = 23.44 \end{aligned}$$

(b) $-4 \leq f''(x) \leq 1 \Rightarrow |f''(x)| \leq 4$, so use $K = 4$, $a = 0$, $b = 3.2$, and $n = 4$ in Theorem 3. So

$$|E_M| \leq \frac{4(3.2 - 0)^3}{24(4)^2} = \frac{128}{375} = 0.341\bar{3}.$$

32. We use Simpson's Rule with $n = 10$ and $\Delta x = \frac{1}{2}$:

$$\begin{aligned} \text{distance} &= \int_0^5 v(t) \, dt \approx S_{10} = \frac{1}{2 \cdot 3}[f(0) + 4f(0.5) + 2f(1) + \cdots + 4f(4.5) + f(5)] \\ &= \frac{1}{6}[0 + 4(4.67) + 2(7.34) + 4(8.86) + 2(9.73) + 4(10.22) \\ &\quad + 2(10.51) + 4(10.67) + 2(10.76) + 4(10.81) + 10.81] \\ &= \frac{1}{6}(268.41) = 44.735 \text{ m} \end{aligned}$$

33. By the Net Change Theorem, the increase in velocity is equal to $\int_0^6 a(t) \, dt$. We use Simpson's Rule with $n = 6$ and $\Delta t = (6 - 0)/6 = 1$ to estimate this integral:

$$\begin{aligned} \int_0^6 a(t) \, dt &\approx S_6 = \frac{1}{3}[a(0) + 4a(1) + 2a(2) + 4a(3) + 2a(4) + 4a(5) + a(6)] \\ &\approx \frac{1}{3}[0 + 4(0.5) + 2(4.1) + 4(9.8) + 2(12.9) + 4(9.5) + 0] = \frac{1}{3}(113.2) = 37.7\bar{3} \text{ ft/s} \end{aligned}$$

34. By the Net Change Theorem, the total amount of water that leaked out during the first six hours is equal to $\int_0^6 r(t) dt$. We use Simpson's Rule with $n = 6$ and $\Delta t = \frac{6-0}{6} = 1$ to estimate this integral:

$$\begin{aligned}\int_0^6 r(t) dt &\approx S_6 = \frac{1}{3}[r(0) + 4r(1) + 2r(2) + 4r(3) + 2r(4) + 4r(5) + r(6)] \\ &\approx \frac{1}{3}[4 + 4(3) + 2(2.4) + 4(1.9) + 2(1.4) + 4(1.1) + 1] \\ &= \frac{1}{3}(36.6) = 12.2 \text{ liters}\end{aligned}$$

The function values were obtained from a high-resolution graph.

35. By the Net Change Theorem, the energy used is equal to $\int_0^6 P(t) dt$. We use Simpson's Rule with $n = 12$ and $\Delta t = (6 - 0)/12 = \frac{1}{2}$ to estimate this integral:

$$\begin{aligned}\int_0^6 P(t) dt &\approx S_{12} = \frac{1}{3}[P(0) + 4P(0.5) + 2P(1) + 4P(1.5) + 2P(2) + 4P(2.5) \\ &\quad + 2P(3) + 4P(3.5) + 2P(4) + 4P(4.5) + 2P(5) + 4P(5.5) + P(6)] \\ &= \frac{1}{6}[1814 + 4(1735) + 2(1686) + 4(1646) + 2(1637) + 4(1609) + 2(1604) \\ &\quad + 4(1611) + 2(1621) + 4(1666) + 2(1745) + 4(1886) + 2052] \\ &= \frac{1}{6}(61,064) = 10,177.\bar{3} \text{ megawatt-hours.}\end{aligned}$$

36. By the Net Change Theorem, the total amount of data transmitted is equal to $\int_0^8 D(t) dt \times 3600$ [since $D(t)$ is measured in megabits per second and t is in hours]. We use Simpson's Rule with $n = 8$ and $\Delta t = (8 - 0)/8 = 1$ to estimate this integral:

$$\begin{aligned}\int_0^8 D(t) dt &\approx S_8 = \frac{1}{3}[D(0) + 4D(1) + 2D(2) + 4D(3) + 2D(4) + 4D(5) + 2D(6) + 4D(7) + D(8)] \\ &\approx \frac{1}{3}[0.35 + 4(0.32) + 2(0.41) + 4(0.50) + 2(0.51) + 4(0.56) + 2(0.56) + 4(0.83) + 0.88] \\ &= \frac{1}{3}(13.03) = 4.34\bar{3}\end{aligned}$$

Now multiply by 3600 to obtain 15,636 megabits.

37. Let $y = f(x)$ denote the curve. Using cylindrical shells, $V = \int_2^{10} 2\pi x f(x) dx = 2\pi \int_2^{10} x f(x) dx = 2\pi I$. Now use Simpson's Rule to approximate I :

$$\begin{aligned}I &\approx S_8 = \frac{10-2}{3(8)} [2f(2) + 4 \cdot 3f(3) + 2 \cdot 4f(4) + 4 \cdot 5f(5) + 2 \cdot 6f(6) \\ &\quad + 4 \cdot 7f(7) + 2 \cdot 8f(8) + 4 \cdot 9f(9) + 10f(10)] \\ &\approx \frac{1}{3}[2(0) + 12(1.5) + 8(1.9) + 20(2.2) + 12(3.0) + 28(3.8) + 16(4.0) + 36(3.1) + 10(0)] \\ &= \frac{1}{3}(395.2)\end{aligned}$$

Thus, $V \approx 2\pi \cdot \frac{1}{3}(395.2) \approx 827.7$ or 828 cubic units.

38. $\text{Work} = \int_0^{18} f(x) dx \approx S_6 = \frac{18-0}{6 \cdot 3} [f(0) + 4f(3) + 2f(6) + 4f(9) + 2f(12) + 4f(15) + f(18)]$
 $= 1 \cdot [9.8 + 4(9.1) + 2(8.5) + 4(8.0) + 2(7.7) + 4(7.5) + 7.4] = 148 \text{ joules}$

39. $\text{Volume} = \pi \int_0^2 (\sqrt[3]{1+x^3})^2 dx = \pi \int_0^2 (1+x^3)^{2/3} dx$. $V \approx \pi \cdot S_{10}$ where $f(x) = (1+x^3)^{2/3}$ and $\Delta x = (2 - 0)/10 = \frac{1}{5}$. Therefore,

$$\begin{aligned}V &\approx \pi \cdot S_{10} = \pi \cdot \frac{1}{5 \cdot 3} [f(0) + 4f(0.2) + 2f(0.4) + 4f(0.6) + 2f(0.8) + 4f(1) \\ &\quad + 2f(1.2) + 4f(1.4) + 2f(1.6) + 4f(1.8) + f(2)] \approx 12.325078\end{aligned}$$

40. Using Simpson's Rule with $n = 10$, $\Delta x = \frac{\pi/2}{10}$, $L = 1$, $\theta_0 = \frac{42\pi}{180}$ radians, $g = 9.8 \text{ m/s}^2$, $k^2 = \sin^2(\frac{1}{2}\theta_0)$, and $f(x) = 1/\sqrt{1 - k^2 \sin^2 x}$, we get

$$\begin{aligned} T &= 4 \sqrt{\frac{L}{g}} \int_0^{\pi/2} \frac{dx}{\sqrt{1 - k^2 \sin^2 x}} \approx 4 \sqrt{\frac{L}{g}} S_{10} \\ &= 4 \sqrt{\frac{1}{9.8}} \left(\frac{\pi/2}{10 \cdot 3} \right) [f(0) + 4f(\frac{\pi}{20}) + 2f(\frac{2\pi}{20}) + \cdots + 4f(\frac{9\pi}{20}) + f(\frac{\pi}{2})] \approx 2.07665 \end{aligned}$$

41. $I(\theta) = \frac{N^2 \sin^2 k}{k^2}$, where $k = \frac{\pi N d \sin \theta}{\lambda}$, $N = 10,000$, $d = 10^{-4}$, and $\lambda = 632.8 \times 10^{-9}$. So
- $$I(\theta) = \frac{(10^4)^2 \sin^2 k}{k^2}, \text{ where } k = \frac{\pi (10^4) (10^{-4}) \sin \theta}{632.8 \times 10^{-9}}. \text{ Now } n = 10 \text{ and } \Delta\theta = \frac{10^{-6} - (-10^{-6})}{10} = 2 \times 10^{-7},$$
- so $M_{10} = 2 \times 10^{-7} [I(-0.0000009) + I(-0.0000007) + \cdots + I(0.0000009)] \approx 59.4$.

42. $f(x) = \cos(\pi x)$, $\Delta x = \frac{20-0}{10} = 2 \Rightarrow$

$$\begin{aligned} T_{10} &= \frac{2}{2} \{f(0) + 2[f(2) + f(4) + \cdots + f(18)] + f(20)\} \\ &= 1[\cos 0 + 2(\cos 2\pi + \cos 4\pi + \cdots + \cos 18\pi) + \cos 20\pi] \\ &= 1 + 2(1 + 1 + 1 + 1 + 1 + 1 + 1 + 1 + 1 + 1) + 1 = 20 \end{aligned}$$

The actual value is $\int_0^{20} \cos(\pi x) dx = \frac{1}{\pi} [\sin \pi x]_0^{20} = \frac{1}{\pi} (\sin 20\pi - \sin 0) = 0$. The discrepancy is due to the fact that the function is sampled only at points of the form $2n$, where its value is $f(2n) = \cos(2n\pi) = 1$.

43. Consider the function f whose graph is shown. The area $\int_0^2 f(x) dx$ is close to 2. The Trapezoidal Rule gives

$$T_2 = \frac{2-0}{2-2} [f(0) + 2f(1) + f(2)] = \frac{1}{2} [1 + 2 \cdot 1 + 1] = 2.$$

The Midpoint Rule gives

$$M_2 = \frac{2-0}{2} [f(0.5) + f(1.5)] = 1[0 + 0] = 0,$$

so the Trapezoidal Rule is more accurate.

44. Consider the function $f(x) = |x - 1|$, $0 \leq x \leq 2$. The area

$\int_0^2 f(x) dx$ is exactly 1. So is the right endpoint approximation:

$R_2 = f(1) \Delta x + f(2) \Delta x = 0 \cdot 1 + 1 \cdot 1 = 1$. But Simpson's Rule approximates f with the parabola $y = (x - 1)^2$, shown dashed, and

$$S_2 = \frac{\Delta x}{3} [f(0) + 4f(1) + f(2)] = \frac{1}{3} [1 + 4 \cdot 0 + 1] = \frac{2}{3}.$$

45. Since the Trapezoidal and Midpoint approximations on the interval $[a, b]$ are the sums of the Trapezoidal and Midpoint approximations on the subintervals $[x_{i-1}, x_i]$, $i = 1, 2, \dots, n$, we can focus our attention on one such interval. The condition $f''(x) < 0$ for $a \leq x \leq b$ means that the graph of f is concave down as in Figure 5. In that figure, T_n is the area of the trapezoid $AQRD$, $\int_a^b f(x) dx$ is the area of the region $AQPRD$, and M_n is the area of the trapezoid $ABCD$, so $T_n < \int_a^b f(x) dx < M_n$. In general, the condition $f'' < 0$ implies that the graph of f on $[a, b]$ lies above the chord joining the points $(a, f(a))$ and $(b, f(b))$. Thus, $\int_a^b f(x) dx > T_n$. Since M_n is the area under a tangent to the graph, and since $f'' < 0$ implies that the tangent lies above the graph, we also have $M_n > \int_a^b f(x) dx$. Thus, $T_n < \int_a^b f(x) dx < M_n$.

46. Let f be a polynomial of degree ≤ 3 ; say $f(x) = Ax^3 + Bx^2 + Cx + D$. It will suffice to show that Simpson's estimate is exact when there are two subintervals ($n = 2$), because for a larger even number of subintervals the sum of exact estimates is exact. As in the derivation of Simpson's Rule, we can assume that $x_0 = -h$, $x_1 = 0$, and $x_2 = h$. Then Simpson's approximation is

$$\begin{aligned}\int_{-h}^h f(x) dx &\approx \frac{1}{3}h[f(-h) + 4f(0) + f(h)] \\ &= \frac{1}{3}h[(-Ah^3 + Bh^2 - Ch + D) + 4D + (Ah^3 + Bh^2 + Ch + D)] \\ &= \frac{1}{3}h[2Bh^2 + 6D] = \frac{2}{3}Bh^3 + 2Dh\end{aligned}$$

The exact value of the integral is

$$\begin{aligned}\int_{-h}^h (Ax^3 + Bx^2 + Cx + D) dx &= 2 \int_0^h (Bx^2 + D) dx \quad [\text{by Theorem 5.5.6(a) and (b)}] \\ &= 2\left[\frac{1}{3}Bx^3 + Dx\right]_0^h = \frac{2}{3}Bh^3 + 2Dh\end{aligned}$$

Thus, Simpson's Rule is exact.

47. $T_n = \frac{1}{2} \Delta x [f(x_0) + 2f(x_1) + \cdots + 2f(x_{n-1}) + f(x_n)]$ and

$M_n = \Delta x [f(\bar{x}_1) + f(\bar{x}_2) + \cdots + f(\bar{x}_{n-1}) + f(\bar{x}_n)]$, where $\bar{x}_i = \frac{1}{2}(x_{i-1} + x_i)$. Now

$$\begin{aligned}T_{2n} &= \frac{1}{2} \left(\frac{1}{2} \Delta x \right) [f(x_0) + 2f(\bar{x}_1) + 2f(x_1) + 2f(\bar{x}_2) + 2f(x_2) + \cdots \\ &\quad + 2f(\bar{x}_{n-1}) + 2f(x_{n-1}) + 2f(\bar{x}_n) + f(x_n)]\end{aligned}$$

$$\begin{aligned}\text{so} \quad \frac{1}{2}(T_n + M_n) &= \frac{1}{2}T_n + \frac{1}{2}M_n \\ &= \frac{1}{4} \Delta x [f(x_0) + 2f(x_1) + \cdots + 2f(x_{n-1}) + f(x_n)] \\ &\quad + \frac{1}{4} \Delta x [2f(\bar{x}_1) + 2f(\bar{x}_2) + \cdots + 2f(\bar{x}_{n-1}) + 2f(\bar{x}_n)] \\ &= T_{2n}\end{aligned}$$

48. $T_n = \frac{\Delta x}{2} \left[f(x_0) + 2 \sum_{i=1}^{n-1} f(x_i) + f(x_n) \right]$ and $M_n = \Delta x \sum_{i=1}^n f\left(x_i - \frac{\Delta x}{2}\right)$, so

$$\frac{1}{3}T_n + \frac{2}{3}M_n = \frac{1}{3}(T_n + 2M_n) = \frac{\Delta x}{3 \cdot 2} \left[f(x_0) + 2 \sum_{i=1}^{n-1} f(x_i) + f(x_n) + 4 \sum_{i=1}^n f\left(x_i - \frac{\Delta x}{2}\right) \right]$$

where $\Delta x = \frac{b-a}{n}$. Let $\delta x = \frac{b-a}{2n}$. Then $\Delta x = 2\delta x$, so

$$\begin{aligned}\frac{1}{3}T_n + \frac{2}{3}M_n &= \frac{\delta x}{3} \left[f(x_0) + 2 \sum_{i=1}^{n-1} f(x_i) + f(x_n) + 4 \sum_{i=1}^n f(x_i - \delta x) \right] \\ &= \frac{1}{3}\delta x [f(x_0) + 4f(x_1 - \delta x) + 2f(x_1) + 4f(x_2 - \delta x) \\ &\quad + 2f(x_2) + \cdots + 2f(x_{n-1}) + 4f(x_n - \delta x) + f(x_n)]\end{aligned}$$

Since $x_0, x_1 - \delta x, x_1, x_2 - \delta x, x_2, \dots, x_{n-1}, x_n - \delta x, x_n$ are the subinterval endpoints for S_{2n} , and since

$\delta x = \frac{b-a}{2n}$ is the width of the subintervals for S_{2n} , the last expression for $\frac{1}{3}T_n + \frac{2}{3}M_n$ is the usual expression for S_{2n} . Therefore, $\frac{1}{3}T_n + \frac{2}{3}M_n = S_{2n}$.

8.8 Improper Integrals

1. (a) Since $\int_1^\infty x^4 e^{-x^4} dx$ has an infinite interval of integration, it is an improper integral of Type I.
- (b) Since $y = \sec x$ has an infinite discontinuity at $x = \frac{\pi}{2}$, $\int_0^{\pi/2} \sec x dx$ is a Type II improper integral.
- (c) Since $y = \frac{x}{(x-2)(x-3)}$ has an infinite discontinuity at $x = 2$, $\int_0^2 \frac{x}{x^2 - 5x + 6} dx$ is a Type II improper integral.
- (d) Since $\int_{-\infty}^0 \frac{1}{x^2 + 5} dx$ has an infinite interval of integration, it is an improper integral of Type I.
2. (a) Since $y = 1/(2x - 1)$ is defined and continuous on $[1, 2]$, the integral is proper.
- (b) Since $y = \frac{1}{2x - 1}$ has an infinite discontinuity at $x = \frac{1}{2}$, $\int_0^1 \frac{1}{2x - 1} dx$ is a Type II improper integral.
- (c) Since $\int_{-\infty}^\infty \frac{\sin x}{1 + x^2} dx$ has an infinite interval of integration, it is an improper integral of Type I.
- (d) Since $y = \ln(x - 1)$ has an infinite discontinuity at $x = 1$, $\int_1^2 \ln(x - 1) dx$ is a Type II improper integral.
3. The area under the graph of $y = 1/x^3 = x^{-3}$ between $x = 1$ and $x = t$ is
 $A(t) = \int_1^t x^{-3} dx = \left[-\frac{1}{2}x^{-2}\right]_1^t = -\frac{1}{2}t^{-2} - \left(-\frac{1}{2}\right) = \frac{1}{2} - 1/(2t^2)$. So the area for $1 \leq x \leq 10$ is
 $A(10) = 0.5 - 0.005 = 0.495$, the area for $1 \leq x \leq 100$ is $A(100) = 0.5 - 0.00005 = 0.49995$, and the area for
 $1 \leq x \leq 1000$ is $A(1000) = 0.5 - 0.0000005 = 0.4999995$. The total area under the curve for $x \geq 1$ is
 $\lim_{t \rightarrow \infty} A(t) = \lim_{t \rightarrow \infty} \left[\frac{1}{2} - 1/(2t^2)\right] = \frac{1}{2}$.

4. (a)

(b) The area under the graph of f from $x = 1$ to $x = t$ is

$$\begin{aligned} F(t) &= \int_1^t f(x) dx = \int_1^t x^{-1.1} dx = \left[-\frac{1}{0.1}x^{-0.1}\right]_1^t \\ &= -10(t^{-0.1} - 1) = 10(1 - t^{-0.1}) \end{aligned}$$

and the area under the graph of g is

$$\begin{aligned} G(t) &= \int_1^t g(x) dx = \int_1^t x^{-0.9} dx = \left[\frac{1}{0.1}x^{0.1}\right]_1^t \\ &= 10(t^{0.1} - 1) \end{aligned}$$

t	$F(t)$	$G(t)$
10	2.06	2.59
100	3.69	5.85
10^4	6.02	15.12
10^6	7.49	29.81
10^{10}	9	90
10^{20}	9.9	990

(c) The total area under the graph of f is $\lim_{t \rightarrow \infty} F(t) = \lim_{t \rightarrow \infty} 10(1 - t^{-0.1}) = 10$.The total area under the graph of g does not exist, since $\lim_{t \rightarrow \infty} G(t) = \lim_{t \rightarrow \infty} 10(t^{0.1} - 1) = \infty$.

$$5. I = \int_1^{\infty} \frac{1}{(3x+1)^2} dx = \lim_{t \rightarrow \infty} \int_1^t \frac{1}{(3x+1)^2} dx. \text{ Now}$$

$$\int \frac{1}{(3x+1)^2} dx = \frac{1}{3} \int \frac{1}{u^2} du \quad [u = 3x+1, du = 3 dx]$$

$$= -\frac{1}{3u} + C = -\frac{1}{3(3x+1)} + C,$$

$$\text{so } I = \lim_{t \rightarrow \infty} \left[-\frac{1}{3(3x+1)} \right]_1^t = \lim_{t \rightarrow \infty} \left[-\frac{1}{3(3t+1)} + \frac{1}{12} \right] = 0 + \frac{1}{12} = \frac{1}{12}. \quad \text{Convergent}$$

$$6. \int_{-\infty}^0 \frac{1}{2x-5} dx = \lim_{t \rightarrow -\infty} \int_t^0 \frac{1}{2x-5} dx = \lim_{t \rightarrow -\infty} \left[\frac{1}{2} \ln |2x-5| \right]_t^0 = \lim_{t \rightarrow -\infty} \left[\frac{1}{2} \ln 5 - \frac{1}{2} \ln |2t-5| \right] = -\infty.$$

30. $\int_1^9 \frac{dx}{\sqrt[3]{x-9}} = \lim_{t \rightarrow 9^-} \int_1^t \frac{dx}{\sqrt[3]{x-9}} = \lim_{t \rightarrow 9^-} \left[\frac{3}{2}(x-9)^{2/3} \right]_1^t = \lim_{t \rightarrow 9^-} \left[\frac{3}{2}(t-9)^{2/3} - \frac{3}{2}(4) \right] = 0 - 6 = -6.$

Convergent

31. $\int_{-2}^3 \frac{dx}{x^4} = \int_{-2}^0 \frac{dx}{x^4} + \int_0^3 \frac{dx}{x^4}$, but $\int_{-2}^0 \frac{dx}{x^4} = \lim_{t \rightarrow 0^-} \left[-\frac{x^{-3}}{3} \right]_{-2}^t = \lim_{t \rightarrow 0^-} \left[-\frac{1}{3t^3} - \frac{1}{24} \right] = \infty. \text{ Divergent}$

32. $\int_0^1 \frac{dx}{\sqrt{1-x^2}} = \lim_{t \rightarrow 1^-} \int_0^t \frac{dx}{\sqrt{1-x^2}} = \lim_{t \rightarrow 1^-} [\sin^{-1} x]_0^t = \lim_{t \rightarrow 1^-} \sin^{-1} t = \frac{\pi}{2}. \text{ Convergent}$

33. There is an infinite discontinuity at $x = 1$. $\int_0^{33} (x-1)^{-1/5} dx = \int_0^1 (x-1)^{-1/5} dx + \int_1^{33} (x-1)^{-1/5} dx$. Here $\int_0^1 (x-1)^{-1/5} dx = \lim_{t \rightarrow 1^-} \int_0^t (x-1)^{-1/5} dx = \lim_{t \rightarrow 1^-} \left[\frac{5}{4} (x-1)^{4/5} \right]_0^t = \lim_{t \rightarrow 1^-} \left[\frac{5}{4} (t-1)^{4/5} - \frac{5}{4} \right] = -\frac{5}{4}$ and $\int_1^{33} (x-1)^{-1/5} dx = \lim_{t \rightarrow 1^+} \int_t^{33} (x-1)^{-1/5} dx = \lim_{t \rightarrow 1^+} \left[\frac{5}{4} (x-1)^{4/5} \right]_t^{33} = \lim_{t \rightarrow 1^+} \left[\frac{5}{4} \cdot 16 - \frac{5}{4} (t-1)^{4/5} \right] = 20$. Thus, $\int_0^{33} (x-1)^{-1/5} dx = -\frac{5}{4} + 20 = \frac{75}{4}$. Convergent

34. $f(y) = 1/(4y-1)$ has an infinite discontinuity at $y = \frac{1}{4}$.

$$\begin{aligned} \int_{1/4}^1 \frac{1}{4y-1} dy &= \lim_{t \rightarrow (1/4)^+} \int_t^1 \frac{1}{4y-1} dy = \lim_{t \rightarrow (1/4)^+} \left[\frac{1}{4} \ln |4y-1| \right]_t^1 \\ &= \lim_{t \rightarrow (1/4)^+} \left[\frac{1}{4} \ln 3 - \frac{1}{4} \ln(4t-1) \right] = \infty \end{aligned}$$

so $\int_{1/4}^1 \frac{1}{4y-1} dy$ diverges, and hence, $\int_0^1 \frac{1}{4y-1} dy$ diverges. Divergent

35. $\int_0^\pi \sec x dx = \int_0^{\pi/2} \sec x dx + \int_{\pi/2}^\pi \sec x dx$. $\int_0^{\pi/2} \sec x dx = \lim_{t \rightarrow \pi/2^-} \int_0^t \sec x dx$
 $= \lim_{t \rightarrow \pi/2^-} \left[\ln |\sec x + \tan x| \right]_0^t = \lim_{t \rightarrow \pi/2^-} \ln |\sec t + \tan t| = \infty$. Divergent

36. $\int_0^4 \frac{dx}{x^2+x-6} = \int_0^4 \frac{dx}{(x+3)(x-2)} = \int_0^2 \frac{dx}{(x-2)(x+3)} + \int_2^4 \frac{dx}{(x-2)(x+3)}$, and
 $\int_0^2 \frac{dx}{(x-2)(x+3)} = \lim_{t \rightarrow 2^-} \int_0^t \left[\frac{1/5}{x-2} - \frac{1/5}{x+3} \right] dx$ [partial fractions] $= \lim_{t \rightarrow 2^-} \left[\frac{1}{5} \ln \left| \frac{x-2}{x+3} \right| \right]_0^t$
 $= \lim_{t \rightarrow 2^-} \frac{1}{5} \left[\ln \left| \frac{t-2}{t+3} \right| - \ln \frac{2}{3} \right] = -\infty$. Divergent

37. There is an infinite discontinuity at $x = 0$. $\int_{-1}^1 \frac{e^x}{e^x-1} dx = \int_{-1}^0 \frac{e^x}{e^x-1} dx + \int_0^1 \frac{e^x}{e^x-1} dx$.
 $\int_{-1}^0 \frac{e^x}{e^x-1} dx = \lim_{t \rightarrow 0^-} \int_{-1}^t \frac{e^x}{e^x-1} dx = \lim_{t \rightarrow 0^-} \left[\ln |e^x-1| \right]_{-1}^t = \lim_{t \rightarrow 0^-} \left[\ln |e^t-1| - \ln |e^{-1}-1| \right] = -\infty$,
 so $\int_{-1}^1 \frac{e^x}{e^x-1} dx$ is divergent. The integral $\int_0^1 \frac{e^x}{e^x-1} dx$ also diverges since
 $\int_0^1 \frac{e^x}{e^x-1} dx = \lim_{t \rightarrow 0^+} \int_t^1 \frac{e^x}{e^x-1} dx = \lim_{t \rightarrow 0^+} \left[\ln |e^x-1| \right]_t^1 = \lim_{t \rightarrow 0^+} \left[\ln |e-1| - \ln |e^t-1| \right] = \infty$.
 Divergent

38. $\int_0^2 \frac{x-3}{2x-3} dx = \int_0^{3/2} \frac{x-3}{2x-3} dx + \int_{3/2}^2 \frac{x-3}{2x-3} dx$ and
 $\int \frac{x-3}{2x-3} dx = \frac{1}{2} \int \frac{2x-6}{2x-3} dx = \frac{1}{2} \int \left[1 - \frac{3}{2x-3} \right] dx = \frac{1}{2} x - \frac{3}{4} \ln |2x-3| + C$, so
 $\int_0^{3/2} \frac{x-3}{2x-3} dx = \lim_{t \rightarrow 3/2^-} \left[\frac{1}{2} t - \frac{3}{4} \ln |2t-3| \right]_0^t = \infty$. Divergent

$$\begin{aligned}
 39. I &= \int_0^2 z^2 \ln z \, dz = \lim_{t \rightarrow 0^+} \int_t^2 z^2 \ln z \, dz \stackrel{101}{=} \lim_{t \rightarrow 0^+} \left[\frac{z^3}{3^2} (3 \ln z - 1) \right]_t^2 \\
 &= \lim_{t \rightarrow 0^+} \left[\frac{8}{9} (3 \ln 2 - 1) - \frac{1}{9} t^3 (3 \ln t - 1) \right] = \frac{8}{3} \ln 2 - \frac{8}{9} - \frac{1}{9} \lim_{t \rightarrow 0^+} [t^3 (3 \ln t - 1)] = \frac{8}{3} \ln 2 - \frac{8}{9} - \frac{1}{9} L.
 \end{aligned}$$

$$\text{Now } L = \lim_{t \rightarrow 0^+} [t^3 (3 \ln t - 1)] = \lim_{t \rightarrow 0^+} \frac{3 \ln t - 1}{t^{-3}} \stackrel{H}{=} \lim_{t \rightarrow 0^+} \frac{3/t}{-3/t^4} = \lim_{t \rightarrow 0^+} (-t^3) = 0. \text{ Thus, } L = 0 \text{ and}$$

$$I = \frac{8}{3} \ln 2 - \frac{8}{9}. \quad \text{Convergent}$$

$$40. \text{ Integrate by parts with } u = \ln x, dv = dx/\sqrt{x} \Rightarrow du = dx/x, v = 2\sqrt{x}.$$

$$\begin{aligned}
 \int_0^1 \frac{\ln x}{\sqrt{x}} \, dx &= \lim_{t \rightarrow 0^+} \int_t^1 \frac{\ln x}{\sqrt{x}} \, dx = \lim_{t \rightarrow 0^+} \left([2\sqrt{x} \ln x]_t^1 - 2 \int_t^1 \frac{dx}{\sqrt{x}} \right) = \lim_{t \rightarrow 0^+} \left(-2\sqrt{t} \ln t - 4[\sqrt{x}]_t^1 \right) \\

 &= \frac{1}{2} \lim_{t \rightarrow \infty} [\ln(t^2 + 9) - \ln 9] = \infty
 \end{aligned}$$

Infinite area

45.

$$\begin{aligned} \text{Area} &= \int_0^{\pi/2} \sec^2 x \, dx = \lim_{t \rightarrow (\pi/2)^-} \int_0^t \sec^2 x \, dx \\ &= \lim_{t \rightarrow (\pi/2)^-} [\tan x]_0^t = \lim_{t \rightarrow (\pi/2)^-} (\tan t - 0) \\ &= \infty \end{aligned}$$

Infinite area

46.

$$\begin{aligned} \text{Area} &= \int_{-2}^0 \frac{1}{\sqrt{x+2}} \, dx = \lim_{t \rightarrow -2^+} \int_t^0 \frac{1}{\sqrt{x+2}} \, dx \\ &= \lim_{t \rightarrow -2^+} [2\sqrt{x+2}]_t^0 = \lim_{t \rightarrow -2^+} (2\sqrt{2} - 2\sqrt{t+2}) \\ &= 2\sqrt{2} - 0 = 2\sqrt{2} \end{aligned}$$

47. (a)

t	$\int_1^t g(x) \, dx$
2	0.447453
5	0.577101
10	0.621306
100	0.668479
1000	0.672957
10,000	0.673407

$$g(x) = \frac{\sin^2 x}{x^2}.$$

It appears that the integral is convergent.

$$(b) -1 \leq \sin x \leq 1 \Rightarrow 0 \leq \sin^2 x \leq 1 \Rightarrow 0 \leq \frac{\sin^2 x}{x^2} \leq \frac{1}{x^2}. \text{ Since } \int_1^\infty \frac{1}{x^2} \, dx \text{ is convergent}$$

(Equation 2 with $p = 2 > 1$), $\int_1^\infty \frac{\sin^2 x}{x^2} \, dx$ is convergent by the Comparison Theorem.

(c)

Since $\int_1^\infty f(x) \, dx$ is finite and the area under $g(x)$ is less than the area under $f(x)$ on any interval $[1, t]$, $\int_1^\infty g(x) \, dx$ must be finite; that is, the integral is convergent.

48. (a)

t	$\int_2^t g(x) \, dx$
5	3.830327
10	6.801200
100	23.328769
1000	69.023361
10,000	208.124560

$$g(x) = \frac{1}{\sqrt{x} - 1}.$$

It appears that the integral is divergent.

(b) For $x \geq 2$, $\sqrt{x} > \sqrt{x} - 1 \Rightarrow \frac{1}{\sqrt{x}} < \frac{1}{\sqrt{x} - 1}$. Since $\int_2^\infty \frac{1}{\sqrt{x}} dx$ is divergent (Equation 2 with

$p = \frac{1}{2} \leq 1$), $\int_2^\infty \frac{1}{\sqrt{x} - 1} dx$ is divergent by the Comparison Theorem.

(c) 2.5

Since $\int_2^\infty f(x) dx$ is infinite and the area under $g(x)$ is greater than the area under $f(x)$ on any interval $[2, t]$, $\int_2^\infty g(x) dx$ must be infinite; that is, the integral is divergent.

49. For $x \geq 1$, $\frac{\cos^2 x}{1+x^2} \leq \frac{1}{1+x^2} < \frac{1}{x^2}$. $\int_1^\infty \frac{1}{x^2} dx$ is convergent by Equation 2 with $p = 2 > 1$, so $\int_1^\infty \frac{\cos^2 x}{1+x^2} dx$ is convergent by the Comparison Theorem.

50. For $x \geq 1$, $\frac{2+e^{-x}}{x} > \frac{2}{x}$ [since $e^{-x} > 0$] $> \frac{1}{x}$. $\int_1^\infty \frac{1}{x} dx$ is divergent by Equation 2 with $p = 1 \leq 1$, so

$\int_1^\infty \frac{2+e^{-x}}{x} dx$ is divergent by the Comparison Theorem.

51. For $x \geq 1$, $x + e^{2x} > e^{2x} > 0 \Rightarrow \frac{1}{x + e^{2x}} \leq \frac{1}{e^{2x}} = e^{-2x}$ on $[1, \infty)$.

$\int_1^\infty e^{-2x} dx = \lim_{t \rightarrow \infty} \left[-\frac{1}{2} e^{-2x} \right]_1^t = \lim_{t \rightarrow \infty} \left[-\frac{1}{2} e^{-2t} + \frac{1}{2} e^{-2} \right] = \frac{1}{2} e^{-2}$. Therefore, $\int_1^\infty e^{-2x} dx$ is convergent,

and by the Comparison Theorem, $\int_1^\infty \frac{dx}{x + e^{2x}}$ is also convergent.

52. For $x \geq 1$, $0 < \frac{x}{\sqrt{1+x^6}} < \frac{x}{\sqrt{x^6}} = \frac{x}{x^3} = \frac{1}{x^2}$. $\int_1^\infty \frac{1}{x^2} dx$ is convergent by Equation 2 with $p = 2 > 1$, so

$\int_1^\infty \frac{x}{\sqrt{1+x^6}} dx$ is convergent by the Comparison Theorem.

53. $\frac{1}{x \sin x} \geq \frac{1}{x}$ on $(0, \frac{\pi}{2}]$ since $0 \leq \sin x \leq 1$. $\int_0^{\pi/2} \frac{dx}{x} = \lim_{t \rightarrow 0^+} \int_t^{\pi/2} \frac{dx}{x} = \lim_{t \rightarrow 0^+} [\ln x]_t^{\pi/2} = \lim_{t \rightarrow 0^+} (\ln \frac{\pi}{2} - \ln t) = -\infty$.

But $\ln t \rightarrow -\infty$ as $t \rightarrow 0^+$, so $\int_0^{\pi/2} \frac{dx}{x}$ is divergent, and by the Comparison Theorem, $\int_0^{\pi/2} \frac{dx}{x \sin x}$ is also divergent.

54. For $0 \leq x \leq 1$, $e^{-x} \leq 1 \Rightarrow \frac{e^{-x}}{\sqrt{x}} \leq \frac{1}{\sqrt{x}}$.

$\int_0^1 \frac{1}{\sqrt{x}} dx = \lim_{t \rightarrow 0^+} \int_t^1 \frac{1}{\sqrt{x}} dx = \lim_{t \rightarrow 0^+} [2\sqrt{x}]_t^1 = \lim_{t \rightarrow 0^+} (2 - 2\sqrt{t}) = 2$ is convergent. Therefore, $\int_0^1 \frac{e^{-x}}{\sqrt{x}} dx$

is convergent by the Comparison Theorem.

$$\begin{aligned}
 55. \int_0^\infty \frac{dx}{\sqrt{x}(1+x)} &= \int_0^1 \frac{dx}{\sqrt{x}(1+x)} + \int_1^\infty \frac{dx}{\sqrt{x}(1+x)} = \lim_{t \rightarrow 0^+} \int_t^1 \frac{dx}{\sqrt{x}(1+x)} + \lim_{t \rightarrow \infty} \int_1^t \frac{dx}{\sqrt{x}(1+x)}. \text{ Now} \\
 \int \frac{dx}{\sqrt{x}(1+x)} &= \int \frac{2u du}{u(1+u^2)} \quad [u = \sqrt{x}, x = u^2, dx = 2u du] \\
 &= 2 \int \frac{du}{1+u^2} = 2 \tan^{-1} u + C = 2 \tan^{-1} \sqrt{x} + C,
 \end{aligned}$$

$$\begin{aligned}
 \text{so } \int_0^\infty \frac{dx}{\sqrt{x}(1+x)} &= \lim_{t \rightarrow 0^+} [2 \tan^{-1} \sqrt{x}]_t^1 + \lim_{t \rightarrow \infty} [2 \tan^{-1} \sqrt{x}]_1^t \\
 &= \lim_{t \rightarrow 0^+} [2(\frac{\pi}{4}) - 2 \tan^{-1} \sqrt{t}] + \lim_{t \rightarrow \infty} [2 \tan^{-1} \sqrt{t} - 2(\frac{\pi}{4})] = \frac{\pi}{2} - 0 + 2(\frac{\pi}{2}) - \frac{\pi}{2} = \pi.
 \end{aligned}$$

$$\begin{aligned}
 56. \int_2^\infty \frac{dx}{x\sqrt{x^2-4}} &= \int_2^3 \frac{dx}{x\sqrt{x^2-4}} + \int_3^\infty \frac{dx}{x\sqrt{x^2-4}} = \lim_{t \rightarrow 2^+} \int_t^3 \frac{dx}{x\sqrt{x^2-4}} + \lim_{t \rightarrow \infty} \int_3^t \frac{dx}{x\sqrt{x^2-4}}. \text{ Now} \\
 \int \frac{dx}{x\sqrt{x^2-4}} &= \int \frac{2 \sec \theta \tan \theta d\theta}{2 \sec \theta \tan \theta} \quad [x = 2 \sec \theta, \text{ where } 0 \leq \theta < \pi/2 \text{ or } \pi \leq \theta < 3\pi/2] \\
 &= \frac{1}{2} \theta + C = \frac{1}{2} \sec^{-1}(\frac{1}{2}x) + C, \text{ so} \\
 \int_2^\infty \frac{dx}{x\sqrt{x^2-4}} &= \lim_{t \rightarrow 2^+} [\frac{1}{2} \sec^{-1}(\frac{1}{2}x)]_t^3 + \lim_{t \rightarrow \infty} [\frac{1}{2} \sec^{-1}(\frac{1}{2}x)]_3^t \\
 &= \frac{1}{2} \sec^{-1}(\frac{3}{2}) - 0 + \frac{1}{2}(\frac{\pi}{2}) - \frac{1}{2} \sec^{-1}(\frac{3}{2}) = \frac{\pi}{4}
 \end{aligned}$$

$$57. \text{ If } p = 1, \text{ then } \int_0^1 \frac{dx}{x^p} = \lim_{t \rightarrow 0^+} \int_t^1 \frac{dx}{x} = \lim_{t \rightarrow 0^+} [\ln x]_t^1 = \infty. \text{ Divergent.}$$

$$\text{If } p \neq 1, \text{ then } \int_0^1 \frac{dx}{x^p} = \lim_{t \rightarrow 0^+} \int_t^1 \frac{dx}{x^p} \quad (\text{note that the integral is not improper if } p < 0)$$

$$= \lim_{t \rightarrow 0^+} \left[\frac{x^{-p+1}}{-p+1} \right]_t^1 = \lim_{t \rightarrow 0^+} \frac{1}{1-p} \left[1 - \frac{1}{t^{p-1}} \right]$$

$$\text{If } p > 1, \text{ then } p-1 > 0, \text{ so } \frac{1}{t^{p-1}} \rightarrow \infty \text{ as } t \rightarrow 0^+, \text{ and the integral diverges.}$$

$$\text{If } p < 1, \text{ then } p-1 < 0, \text{ so } \frac{1}{t^{p-1}} \rightarrow 0 \text{ as } t \rightarrow 0^+ \text{ and } \int_0^1 \frac{dx}{x^p} = \frac{1}{1-p} \left[\lim_{t \rightarrow 0^+} (1 - t^{1-p}) \right] = \frac{1}{1-p}.$$

Thus, the integral converges if and only if $p < 1$, and in that case its value is $\frac{1}{1-p}$.

$$58. \text{ Let } u = \ln x. \text{ Then } du = dx/x \Rightarrow \int_e^\infty \frac{dx}{x(\ln x)^p} = \int_1^\infty \frac{du}{u^p}. \text{ By Example 4, this converges to } \frac{1}{p-1} \text{ if } p > 1 \text{ and diverges otherwise.}$$

$$59. \text{ First suppose } p = -1. \text{ Then}$$

$$\int_0^1 x^p \ln x \, dx = \int_0^1 \frac{\ln x}{x} \, dx = \lim_{t \rightarrow 0^+} \int_t^1 \frac{\ln x}{x} \, dx = \lim_{t \rightarrow 0^+} \left[\frac{1}{2} (\ln x)^2 \right]_t^1 = -\frac{1}{2} \lim_{t \rightarrow 0^+} (\ln t)^2 = -\infty,$$

so the integral diverges. Now suppose $p \neq -1$. Then integration by parts gives
